ABOUT ESCEO

The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) is a not-for-profit organization, dedicated to a close interaction between clinical scientists dealing with bone, joint and muscle disorder, pharmaceutical industry developing new compounds in this field, regulators responsible for the registration of such drugs and health policy makers, to integrate the management of Osteoporosis and Osteoarthritis within the comprehensive perspective of health resources utilization.

The objective of ESCEO is to provide practitioners with the latest clinical and economic information, allowing them to organize their daily practice, in an evidence-based medicine perspective, with a cost-conscious perception.

www.esceo.org

ABOUT IOF

The International Osteoporosis Foundation (IOF) is the world's largest nongovernmental organization dedicated to the prevention, diagnosis, and treatment of osteoporosis and related musculoskeletal diseases. Its members — including committees of leading scientific researchers and 349 patient, medical, and research organizations across 152 countries — work together to make fracture prevention and healthy mobility a global healthcare priority.

www.osteoporosis.foundation

Mission

- Increase awareness and understanding of osteoporosis.
- Motivate people to take action to prevent, diagnose and treat osteoporosis.
- Support national osteoporosis societies in order to maximize their effectiveness

DEAR COLLEAGUES,

We are delighted to welcome you to the 2026 IOF-ESCEO World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases in Prague.

The Congress' scientific programme has been developed by a team comprising members of the Committee of Scientific Advisors of the International Osteoporosis Foundation (IOF) and the Scientific Advisory Board of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO). We would like to thank the respective Scientific Programme Chairs — Professors Nicholas Harvey and René Rizzoli — for taking the lead in shaping a comprehensive programme that brings together the world's leading experts in musculoskeletal health and disease, while fully leveraging the synergies and combined expertise of our two organisations. Additionally, we extend our sincere thanks to the local organising society, the Czech Society of Metabolic Bone Diseases, for their invaluable support and collaboration.

With a shared goal, we come together to acquire new knowledge, skills and tools for preventing and treating osteoporosis, osteoarthritis and sarcopenia, the most common and disabling musculoskeletal conditions affecting older adults. Specific related focus areas of this year's meeting include novel care pathways for structured post-fracture follow-up and secondary prevention, the role of obesity and diabetes in bone and joint health and advances in long-term osteoporosis management, as well as emerging topics such as the musculoskeletal effects of GLP-1 receptor agonists, AI in clinical practice and global challenges in bone health management, among many other cutting edge topics. By presenting innovative strategies and new options for prevention, diagnosis, and treatment, this Congress will advance the field for the benefit of patients worldwide.

The core scientific programme consists of **10** plenary lectures by renowned speakers and **41** oral communications selected from the very best of hundreds of submitted abstracts, and **22** oral presentations of selected posters. In addition, participants can choose among **10** different Meet-The-Expert sessions and **14** special sessions and symposia on issues of clinical importance. We also encourage you to attend the scheduled poster sessions and the industry-sponsored satellite symposia. Be sure to visit the large commercial exhibition, presented by leading companies in the bone field, as well as the 'CNS Village,' where you can meet IOF's member societies from around the world.

We are proud to share that our World Congress, the largest in the field, continues to set new records each year for attendance and abstract submissions. We are especially grateful for your ongoing support and engagement and are committed to making this meeting a memorable and enriching experience for all.

PRE-COMPETITIVE CONSORTIUM ON OSTEOPOROSIS AND BONE HEALTH

An initiative from ESCEO and IOF to support the five-year partnership signed between ESCEO and the World Health Organization to improve the management of osteoporosis

ESCEO and IOF are very proud to announce the creation of the Pre-Competitive Consortium on Osteoporosis and Bone Health (PRECCO). This Consortium, created to support the five-year partnership signed between ESCEO and the **World Health Organization** to improve the management of osteoporosis, involves a diverse range of stakeholders, who place the osteoporotic patients at the center of their priorities, independently of their immediate strategy, in terms of content and timeline. The stakeholders supporting the PRECCO are listed below.

ECHOLIGHT · MEDIMAPS We understand bone health · IBSA Institute Biochimique SA · VIATRIS

ABIOGEN PHARMA · GEDEON RICHTER · angitia · IBEX BH Bone Health

RADIUS® · Theramex For Women, For Health · OSTEOPOROSIS RESEARCH LIMITED · CELLTRION

3D-SHAPER · BINDEX Osteoporosis Diagnostics · 16BIT · MONASH University

08:00 - 09:00
NON-SPONSORED SYMPOSIA

MR - D9 **Musculoskeletal Aging: where East meets West**
Chairperson: Elaine Dennison
- Musculoskeletal aging in the oldest old: when East meets West Elaine Dennison
- The ROAD study: an overview Noriko Yoshimura
- The SALSA study: an overview Faidra Laskou
- How does musculoskeletal health and its determinants in East and West differ? Leo Westbury

MR - D8 **Cardiovascular Comorbidities in Osteoporosis: WHO Report**
Chairperson: Joshua Lewis
- Move to Improve: Osteoporosis, Cardiovascular Risk, and the Role of Exercise in Healthy Aging Cassandra Smith
- Bone Appétit: Influence of Cardiovascular Disease on Musculoskeletal Health: A Key Role for Nutrition? Marc Sim
- A Model of Atherosclerotic Calcifications as a Consequence of Osteoporosis Gordon Klein
- Q&A

MR - D3 **The metabolic profile of psoriatic disease. Obesity, musculoskeletal manifestations and management**
Chairperson: Panagiotis Athanassiou
- Psoriatic disease Lambros Athanassiou
- Psoriatic disease and metabolic syndrome Yannis Dionyssiotis
- Psoriatic disease and obesity Yannis Athanassiou, Ifigenia Kostoglou-Athanassiou
- Psoriatic disease and treatment Panagiotis Athanassiou

MR- D4 **Standardizing Periprosthetic DXA in Hip and Knee Arthroplasty: From Variability to Robust Data**
Chairpersons: Jose Francisco Torres-Naranjo, Cristina Ojeda-Thies
- Why Periprosthetic DXA Needs Standardization: Evidence, Variability, and the RAND/UCLA Process Iñigo Etxebarria Foronda
- From Pixels to Protocols: A Practical Framework for High-Quality Periprosthetic DXA Jose Francisco Torres-Naranjo
- Interpreting Perprosthetic BMD: Precision, Longitudinal Change, and Therapy-Aware Flags Roberto Enrique Lopez-Cervantes

MR - D1 **Capture the Fracture - Building High-Quality Fracture Liaison Services: Practical Lessons from Global Experience**
Chairperson: Maria Luisa Brandi
- The FLS history in Italy: A decade of action Maria Luisa Brandi
- Learning from peers and building a strong FLS community – the Japanese experience Atsushi Suzuki
- A set of variables for the assessment of Fragility Fracture patients in an FLS environment in Latin America (Country Specific Datasets) Monica Calo
- Q&A

08:00 - 09:00 - MR - C1
ESCEO MEETS DVO Current highlights in Osteology

Chairpersons: Ralf Schmidmaier, Manju Chandran
- One for all? Scoring of vertebral fractures? Uwe Maus
- Treatment induced osteoporosis in women with breast cancer - the updated position statement Peyman Hadji
- Fracture and Osteoporosis - Riskfactor, Endpoint, Complication,Treatment Andreas Kurth

08:00 - 09:00 - MR - D12
ESCEO SYMPOSIUM

Update of the 2017 recommendations for the use of Hyaluronic Acid injections in patients with knee osteoarthritis: a patient-centered experts' consensus

Chairpersons: François Rannou, Ali Mobasheri
- Efficacy of IAHA in osteoarthritis Olivier Bruyère
- Safety of IAHA in osteoarthritis Emmanuel Maheu
- New perspectives in the use of IAHA for the management of osteoarthritis Nicholas Fuggle
- Discussion leaders Elaine Dennison, Alberto Migliore

09:00 - 10:30 - Auditorium 1
SCIENTIFIC SESSION I

Chairpersons: Charlotte Beaudart, Peter Ebeling

09:00 **Plenary Lecture**
Management of very high fracture risk in the context of a lifelong osteoporosis treatment plan
Michael McClung

09:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

09:30 **OC1** PREDICTIVE VALUE OF BMD FOR HIP AND OTHER FRACTURES A META-ANALYSIS TO UPDATE FRAX
Presenting author: E. McCloskey
Authors: N. C. Harvey, H. Johansson, E. Liu, L. Vandenput, M. Lorentzon, W. D. Leslie, J. A. Kanis, Frax Meta-Analysis Cohort Group

09:40 **OC2** LIFE EXPECTANCY FOLLOWING FIRST DXA - ARE MEN REFERRED TOO LATE? AN ANALYSIS OF THE 1900-1960 BIRTH COHORT
Presenting author: B. Abrahamsen
Authors: B. Bakke Hansen, B. Haddock, N. Rye Jørgensen, P. Vestergaard, U. Kock Wiil, L. Folkestad, S. Möller, B. Langdahl, K. Hass Rubin

09:50 **OC3** EARLY INITIATION OF OSTEOPOROSIS TREATMENT AFTER FRACTURE REDUCES SECONDARY FRACTURES IN ADULTS AGED ≥75 YEARS
Presenting author: M. Tsukamoto
Authors: T. Hamasaki, N. Okimoto, Y. Saito, S. Fujiwara

10:00 **OC4** TIMING OF ANTI-OSTEOPOROTIC TREATMENT INITIATION AFTER VERTEBRAL FRACTURE AND RISK OF NEW FRACTURE IN A FLS MODEL
Presenting author: N. Padron Orozco
Authors: P. Perez Andrés, C. Reyes Diez, M. J. Montesa Cabrera, B. Gonzalez Alvarez

10:10 **OC5** THE NUMBER NEEDED TO TREAT (NNT) ANALYSIS: A CLINICAL CONTEXT FOR THE TREATMENT-RELATED CHANGE IN TOTAL HIP BONE MINERAL DENSITY: THE ASBMR-SABRE PROJECT
Presenting author: T. Vilaca
Authors: L. Lui, M. Schini, S. K. Ewing, A. Thompson, E. Vittinghoff, D. C. Bauer, B. Langdahl, D. Black, M. Bouxsein, R. Eastell

10:20 **OC6** ADHERENCE TO CARDIOVASCULAR RISK MINIMIZATION MEASURES FOR ROMOSOZUMAB INTERIM RESULTS FROM A EUROPEAN MULTI-DATABASE DRUG UTILISATION STUDY
Presenting author: E. H. Tan
Authors: T. Rathod-Mistry, M. T. Sanchez-Santos, C. Reyes, M. Far, J. Reinold, L. Pederson, B. Darvalics, K. Verhamme, A. Brutau Abia, F. Riefolo, P. Beukelaers, S. Lisart, A. Moayerri, D. Prieto-Alhambra

10:30 - 12:15 - Auditorium 1
SCIENTIFIC SESSION II

Chairpersons: Radmila Matijevic, Etienne Cavalier

10:30 **Presentation of the 2026 ESCEO Medal of Excellence** Jean-Yves Reginster

10:40 **Plenary Lecture**
Barriers and facilitators for orthogeriatric success Celia Gregson

11:10 **OC7** REVISED SWEDISH FRAX MODELS AND THE ESTABLISHMENT OF AGE-DEPENDENT INTERVENTION THRESHOLDS
Presenting author: K. Axelsson
Authors: H. Litsne, N. C. Harvey, J. A. Kanis, E. McCloskey, H. Johansson, M. Lorentzon

11:20 **OC8** IMPROVED 10-YEAR FRACTURE RISK PREDICTION WITH THE “;BONE STRAIN INDEX“; BEYOND BONE MINERAL DENSITY AND FRAX IN COMMUNITY-DWELLING OLDER WOMEN
Presenting author: J.-J. Body
Authors: J. M. K. De Filette, A. Bellanger, L. Rinaudo, F. M. Ulivieri, I. Calderone, S. Cuttone, D. Sanchez-Rodriguez, F. Baleanu, A.-S. Hambye, F. Benoit, M. Surquin, L. Iconaru, P. Bergmann

11:30 **OC9** EROSIVE HAND OSTEOARTHRITIS IS ASSOCIATED WITH INCREASED RISK OF INCIDENT OSTEOPOROTIC FRACTURES IN POST-MENOPAUSAL WOMEN (QUALYOR COHORT)
Presenting author: M. Auroux
Authors: A. Mercier-Guery, A. Piot, B. Merle, M. Proriol, E. Fontanges, E. Duvert, E. Lespessailles, R. Chapurlat

11:40 **OC10** MUSCULOSKELETAL HEALTH AND LIFE-SPACE MOBILITY, SOCIAL ISOLATION AND LONELINESS IN THE OLDEST OLD FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY
Presenting author: L. Westbury
Authors: G. Bevilacqua, H. P. Patel, F. Laskou, E. M. Dennison

11:50 **OC11** BONE COMPONENT DISORGANIZATION IN METABOLIC AND GENETIC BONE DISEASES, INCLUDING HYPOPHOSPHATASIA NOVEL INSIGHTS INTO DISEASE PATHOGENESIS AND PATIENT ASSESSMENT
Presenting author: R. Zebaze
Authors: C. Chiang, C. Shore-Lorenti, F. Milat, R. Ebeling

12:00 **OC12** FREQUENCY OF ECTOPIC CALCIFICATIONS AMONG PATIENTS WITH HYPOPHOSPHATASIA IN THE GLOBAL HPP REGISTRY
Presenting author: P. Ebeling
Authors: A. Linglart, K. M. Dahir, P. S. Kishnani, A. Petryk, L. K. Burke, S. Fang, W. Högler, G. A. Martos Moreno, C. Rockman-Greenberg, L. Seefried, K. Ozono

12:15 - 13:45 - Auditorium 1
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

12:15 - 13:45 - Auditorium 2
SPONSORED LUNCH SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

14:00 - 15:00
MEET-THE-EXPERT SESSION

MR - D9 **PTH, vitamin D and bone turnover markers from the laboratory perspective: more than you can eat!** Etienne Cavalier

MR - D8 **Skeletal microarchitecture and fracture risk** Roland Chapurlat

MR - D1 **FLS: current global challenges** Manju Chandran

MR - D2 **Managing bone health after bariatric surgery** Bernard Cortet

14:00 - 15:00 - MR- D4
EDUCATIONAL LECTURE
Revolution in Osteoporosis Patient Care Necessity, Opportunities, Possibilities and Results. The Czech Paradigm
Chairpersons: Eugene McCloskey, Vladimir Palicka, Richard Pikner

- Osteoporosis Care in the Czech Republic: where we are and where we go Vladimir Palicka
- Czech National Population Programme for Early Detection of Osteoporosis - Methodology, Principles, and 30 Months Results Richard Pikner
- Discussion

14:00 - 15:00 - Podium
ORAL PRESENTATIONS OF SELECTED POSTERS
Chairperson: Elaine Dennison

14:00 **OP1 - P416** FROM WRIST TO HIP CAN EARLY FLS INTERVENTION AFTER A DISTAL RADIUS FRACTURE PREVENT THE NEXT FRAGILITY FRACTURE
Presenting author: C. Singh
Authors: A. E. Elsalamwy, D. C. Charchoglyan, S. Z. Zidan

14:06 **OP2 - P1154** ASSOCIATION BETWEEN THE TREATMENT-RELATED CHANGE IN BONE MINERAL DENSITY AND FRACTURE RISK REDUCTION ACCORDING TO THE PRE-TREATMENT BMD ANALYSIS FROM THE FNIH-ASBMR SABRE PROJECT
Presenting author: M. Schini
Authors: L. Lui, T. Vilaca, S. K. Ewing, A. Thompson, B. L. Langdahl, D. M. Black, M. L. Bouxsein, R. Eastell

14:12 **OP3 - P1770** REAL-WORLD TREATMENT STRATEGIES FOR OSTEOPOROSIS IN OLDER ADULTS WITH CKD-MBD IMPACT OF GERIATRIC SYNDROMES AND TREATMENT COMPLIANCE
Presenting author: S. Z. Şahin Tırnova
Authors: E. Pınar, Z. Fetullahoğlu, D. Seyithanoğlu, H. Arıcı, T. Erdoğan, S. Öztürk, O. Soyluk Selçukbiricik, G. Yenidünya Yalın, N. Gül, A. S. Artan, M. A. Karan, G. Bahat

14:18 **OP4 - P365 -** GLP-1 RECEPTOR AGONISTS AND MUSCULOSKELETAL OUTCOMES A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS
Presenting author: C. Beaudart
Authors: Y. Malréchauffé, S. van Heden, D. Sanchez-Rodriguez, A. Scheen, O. Bruyère, A. Mobasheri, G. Duque, R. Rizzoli, J.-Y. Reginster

14:24 **OP5 - P1076** BISPHOSPHONATES OR DENOSUMAB AFTER FRACTURE? REAL-WORLD EVIDENCE FROM A TARGET TRIAL EMULATION IN MULTIMORBID ADULTS
Presenting author: M. Lin
Authors: T. Tran, R. Blank, J. R. Center, D. Bliuc

14:36 **OP6 - P806** HIP BONE COMPARTMENT RESPONSES TO ROMOSOZUMAB VERSUS ALENDRONATE IN PATIENTS WITH DIABETES A SUBGROUP ANALYSIS FROM THE ARCH TRIAL USING 3D-DXA MODELLING
Presenting author: S. Ferrari
Authors: N. Napoli, B. L. Langdahl, K. Luijtens, J. Timoshanko, L. Humbert, M. Bracco

14:42 **OP7 - P261** THE EFFECTIVENESS OF THE INTENSIVE CARE PROGRAM FOR FLS IMPLEMENTATION TO REDUCE MORPHOMETRIC VERTEBRAL FRACTURES IN OSTEOPOROSIS PATIENTS AT VERY HIGH FRACTURE RISK COMPARED TO THE PRIMARY CARE PHYSICIAN-LED STANDARD CARE JOINT-08 TRIAL
Presenting author: A. Suzuki
Authors: H. Hagino, Y. Uemura, J. Iwamoto, S. Tanaka, Y. Takeuchi, S. Tanaka, S. Soen, E. Hamaya, J. Shimauchi, K. M. Javaid

Authors: Beaudart, Y. Malréchauffé, S. van Heden, D. Sanchez-Rodriguez, A. Scheen, O. Bruyère, A. Mobasheri, G. Duque, R. Rizzoli, J.-Y. Reginster

15:42 **OCs5 - FRAGILITY RUNS IN THE FAMILY** INTERGENERATIONAL CLUSTERING OF OSTEOPOROSIS IN A RURAL INDIAN COHORT
Presenting author: L. Nagendra
Authors: O. Deshmukh, C. Yajnik, On Behalf Of The Pune Maternal Nutrition Study

15:50 **Presentation of the IOF Committee of National Societies Medal** Famida Jiwa

15:55 **Presentation of the CNS Best Booth Award** Philippe Halbout

16:00 **OCs6** DEVELOPMENT AND VALIDATION OF DIABETES HIP FRACTURE SCORE (D-HFS) IN PATIENTS WITH TYPE 2 DIABETES A POPULATION-BASED COHORT STUDY OF HONG KONG
Presenting author: D. T.-W. Lui
Authors: Y. Zhang, C. H.-Y. Fong, M. Chandran, W.-S. Chow, K. C.-B. Tan, C.-H. Lee, Y.-C. Woo, K. S.-L. Lam

16:08 **OCs7** LIFESTYLE AND CLINICAL FACTORS ASSOCIATED WITH FEMORAL NECK BONE MINERAL DENSITY IN AFRICAN ADULTS FINDINGS FROM THE FRACTURE-E3 STUDY
Presenting author: C. Pearse
Authors: L. S. Gates, A. J. Burton, M. K. Jallow, T. Manyanga, C. Grundy, N. J. Crabtree, E. M. Clark, H. Wilson, A. M. Manyara, T. Madanhire, B. Cassim, R. A. Ferrand, C. L. Gregson, K. A. Ward

16:16 **OCs8** USING RESEARCH TO TRANSFORM HEALTH POLICY FOR PATIENTS WITH FRAGILITY FRACTURE IN BRITISH COLUMBIA, CANADA
Presenting author: S. Singh
Authors: L. Funnell, J. Solarzano, L. Battersby, L. Li, T. Bubela, D. Whitehurst, S. Hejazi, S. Bayat, T. O'Callaghan, A. Godfreyson, I. Matthes, B. Ballantyne, L. Matheson-Jennings, J. Robinson, R. Kherani, A. Tecson, O. Slavutskiy, A. Virk

16:24 **OCs9 - OSTEOSARCOPENIA AND RISK OF ALL- CAUSE MORTALITY FOR COMMUNITY-DWELLING OLDER ADULTS** THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM
Presenting author: G. Shafiee
Authors: N. Fahimfar, M. Sanjari, K. Khalagi, I. Nabipour, R. Heshmat

16:32 **OCs10 - AI-ASSISTED OPPORTUNISTIC DETECTION OF VERTEBRAL COMPRESSION FRACTURES IN CT SCANS** OCS10 - AI-ASSISTED OPPORTUNISTIC DETECTION OF VERTEBRAL COMPRESSION FRACTURES IN CT SCANS
Presenting author: A. Cheung
Authors: R. Bleakney, A. Kamona, F. Alavi, E. V. Navarro, Y. Zhang, T. Chung, H.-J. Jang, A. M. Cheung

15:00 - 17:00 - Auditorium 1
SCIENTIFIC SESSION III
Chairpersons: Richard Pikner, Patricia Clark

15:00 **Plenary Lecture**
Hyperglycaemia and bone health: disease and therapy Kate Ward

15:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

15:30 **OC13** INCIDENCE OF NEW OSTEOPOROTIC FRACTURES UP TO THREE YEARS OF FOLLOW-UP IN SUBJECTS WITH TYPE 2 DIABETES MELLITUS WHO INITIATE ANY OSTEOPOROSIS MEDICATION COMPARED TO NON-DIABETICS A POPULATION-BASED COHORT STUDY
Presenting author: L. Gomez Rodriguez
Authors: C. Carbonell-Abella, P. Satorra Herbera, C. Reyes, M. A. Pou Gimenez, C. Diaz Torné, D. Martinez-Laguna, C. Tebé-Cordomí

15:40 **OC14** TYPE 2 DIABETES MELLITUS AND FRACTURE RISK AN INTERNATIONAL META-ANALYSIS
Presenting author: N. C. Harvey
Authors: E. M. Curtis, H. Johansson, L. Westbury, E. V. McCloskey, E. Liu, L. Vandenput, D. P. Kiel, M. Lorentzon, W. D. Leslie, J. A. Kanis, Frax Meta-Analysis Cohort Group

15:50 **OC15** LONGITUDINAL EFFECTS OF DENOSUMAB, ROMOSOZUMAB, AND COMBINATION THERAPY ON MUSCLE QUALITY AND METABOLIC PROFILES A RANDOMIZED CONTROLLED TRIAL
Presenting author: H.-K. Yen
Authors: J. Y. Hsu, C. C. Hung, S. H. Fu, C. Y. Wang

16:00 **OC16** PREGNANCY-RELATED CHANGES IN BONE HEALTH A LONGITUDINAL REMS-BASED STUDY
Presenting author: V. A. Degennaro
Authors: S. Casciaro, F. Conversano, F. A. Lombardi, G. Peluso, P. Pisani, T. Ghi

16:10 **OC17** COST-EFFECTIVENESS OF AI-ENHANCED OPPORTUNISTIC OSTEOPOROSIS SCREENING USING CHEST RADIOGRAPHS EVIDENCE FROM SIX INTERNATIONAL ANALYSES
Presenting author: M. Hiligsmann
Authors: M. Alokail, J.-Y. Reginster

16:20 **OC18** CLINICALLY INTERPRETABLE PREDICTORS OF IMMINENT SUBSEQUENT FRACTURES IN A DEEP-LEARNING PREDICTION MODEL
Presenting author: H. Nguyen
Authors: T. Tran, D. Bliuc, R. Blank, C. White, J. Center

16:30 **Plenary Lecture**
Is there a role for sex hormones in the management of musculoskeletal disorders? Tommaso Simonicini

17:00 - 18:30 - Auditorium 1
SPONSORED SATELLITE SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

18:30 - 19:30
NON-SPONSORED SYMPOSIA

MR - C1 **Bone Turnover Markers in CKD-Associated Osteoporosis: Translating European Consensus to Practice**
Chairpersons: Maria Fusaro, Etienne Cavalier
- Applying Bone Turnover Markers in Dialysis and Transplantation: Case-Based Insights Thomas Nickolas
- BALP, TRACP-5b and iPINP: New Reference Markers and Diagnostic Cut-offs in CKD Hanne Skou Jørgensen

MR - D9 **Clinical Outcomes of Sarcopenia: A GLIS Symposium**
Chairpersons: Alfonso Cruz Jentoft, Jean-Yves Reginster
- The Global Leadership Initiative on Sarcopenia (GLIS): objectives, structure, and achievements Alfonso Cruz Jentoft
- Health outcomes of sarcopenia: Insights from the GLIS Outcome Working Group and clinical implications Gustavo Duque
- Updated meta-analysis on the health outcomes of sarcopenia Charlotte Beaudart

MR - D12 **Mind Body Exercises: Yoga and its effect on Bone and Muscle Health: Myth, Magic, or Measurable Impact?**
Chairperson: Ambrish Mithal
- Introduction to Yoga and Its Relevance to Musculoskeletal Health Manju Chandran
- Effect of Yoga on bone mineral metabolism Lakshmi Nagendra
- Effect of yoga on muscle strength Paras Bajaj
- Yoga demonstration
- Q&A

MR - D2 **Women's Bone Health and Hormones Therapy Update: Integrating Gynecology Into Multidisciplinary Osteoporosis Care**
Chairpersons: Maria Celeste Osório Wender, Adriana Orcesi Pedro

- Estradiol Therapy in 2025: Optimizing Type, Dose, and Route for Bone Protection Across Menopausal Stages Maria Celeste Osório Wender
- Beyond Endometrial Safety: Do Different Progestogens Change Long-Term Skeletal and Metabolic Risk? Jaime Kulak Junior
- Androgens and the Female Musculoskeletal System: Evidence, Gaps, and the Future of Therapy Adriana Orcesi Pedro
- Q&A

MR - D3 **Osteoporosis in Inflammatory Diseases: Clinical Challenges and Diagnostic Gaps**
Chairperson: Elena Bischoff

- High prevalence of osteoporosis in autoimmune and inflammatory diseases Elena Bischoff
- Clinical Challenges and Diagnostic Gaps: REMS technology Mira Hristova

MR - D4 **Managing Bone Fragility in Older Adults with Diabetes: Pathophysiology, Assessment, and Therapeutic Considerations in Older Adults**
Chairpersons: Gulistan Bahat, Dilek Gogas Yavuz

- Pathophysiology, Risk Assessment Challenges, and Non-Pharmacological Strategies in Diabetic Bone Fragility Tugba Erdogan
- Skeletal Effects of Anti-Diabetic Drugs and Osteoporosis Management in Patients with Diabetes Serdar Ozkok

MR - D1 **Artificial Intelligence in Osteoporosis: What's new and what's next**
Chairperson: Nicholas Fuggle

- The AI Landscape in Bone Health 2026: From Multimodal Models to Clinical Agents Nicholas Fuggle
- Current ML models for predicting fracture risk - Do they meet the clinical need and if not then what are the next steps? Bo Abrahamsen
- Ensuring Safe, Equitable, and Regulated AI in Osteoporosis Care Ankeet Tanna

MR - D7 **Kidney and bone health in hypoparathyroidism**
Chairperson: Maria Luisa Brandi

- Kidney health in hypoparathyroidism Jean-Philippe Bertocchio
- Bone health in hypoparathyroidism Aliya Khan

MR - D8 **Hip Fracture and Osteoporosis**
Chairperson: Christopher Niedhart

- Hip Biomechanics and Fracture Risk: Beyond Bone Density Andreas Kurth
- Management of Hip Fractures – The German Approach Katharina Michalke
- Local Bone Augmentation to Prevent Hip Fractures Uwe Maus

08:00 - 09:00

NON-SPONSORED SYMPOSIA

MR - D9 Update in Musculoskeletal Conditions with Hand Involvement

Chairpersons: Fitnat Dincer, Andreas Winkelmann

- Update in Degenerative joint disease of Hand, Osteoarthritic Hand Fitnat Dincer
- Update in Soft tissue lesions /non articular involvement of Hand Andreas Winkelmann

MR - D8 Music, Rhythm, Music, and Cognition: Implementing Dalcroze Eurhythmics to Preserve Capacity in Care Home Residents

Chairpersons: Yasser El Miedany, Naglaa Gadallah

- The Neurological Symphony: Rhythmic Auditory-Motor Coupling and Dual-Task Training Effects of Eurhythmics on Balance and Executive Function Naglaa Gadallah
- "The Moving Body": Developing a Scalable and Safe Dalcroze Protocol for Older Adults with Varying Cognitive and Physical Limitations in Residential Care Mohamed Hassan Abu Zaid
- Beyond Falls: Assessing the Impact of Dalcroze Eurhythmics on Quality of Life, Social Engagement, and Care Home Service Cost-Effectiveness Yasser El Miedany

MR - D1 Muscle impairment in patients with rheumatic diseases: A pragmatic approach

Chairpersons: Osvaldo Daniel Messina, Jorge Luis Alberto Morales-Torres

- Introduction: the need for pragmatic approaches for patients at risk. Osvaldo Daniel Messina, Jorge Luis Alberto Morales-Torres
- Muscle impairment: the problem with outcomes Gustavo Duque
- Muscle impairment: adapting diagnosis to joint limitations Jorge Luis Alberto Morales-Torres
- Muscle impairment: primary and secondary prevention today Osvaldo Daniel Messina
- Discussion and conclusions

MR - D2 Multimorbidity and Fracture Outcomes

Chairpersons: Jacqueline R. Center, Robert D. Blank

- Multimorbidity contribues to the osteoporosis treatment gap. Dana Bliuc
- Multimorbidity double burden: Elevated fracture risk despite high mortality following fracture. Mike Lin
- Risk stratification for imminent subsequent fractures: A DeepHit approach using administrative health data. Huy Nguyen

MR- D4 Low-dose Radiotherapy in Musculoskeletal Disorders: Emerging Strategies for Pain Management and Inflammatory Modulation

Chairperson: África Fernández Forné

- Low-dose radiotherapy in degenerative musculoskeletal disorders: From radiobiological principles to clinical practice. África Fernández Forné
- Beyond conventional therapies: A rheumatologist's perspective on the management of complex and refractory patients. Nerea Costas Torrijo
- Building clinical evidence: Preliminary results from the FINGERT and TROCANTERT studies José Pardo Masferrer
- Discussion and Q&A

MR - D7 Emphasizing the importance of osteoporotic vertebral fractures: focus on diagnosis and care.

Chairperson: Anabela Barcelos

- Early Detection of Vertebral Fragility Fractures: Bridging the Diagnostic Gap Luís C. Semedo
- Opportunistic diagnosis of vertebral fractures using routine CT-scans: the Portuguese experience and literature review Ana Paula Barbosa
- Assessing Quality of Life After Vertebral Fracture: The Value of the Portuguese-Validated QUALEFFO-41 Over Generic Instruments Sofia Azevedo
- Closing remarks Anabela Barcelos

08:00 - 09:00 - Auditorium 1
SPONSORED SATELLITE SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

08:00 - 09:00 - Auditorium 2
SPONSORED BREAKFAST SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

08:00 - 09:00 - MR - D12
ESCEO AND IOF MEET WFS
Fracture Prevention in Older Adults
Chairpersons: Tahir Masud, Nicholas C. Harvey

- Pharmacological treatments for osteoporosis in the oldest older persons Nicholas C. Harvey
- The interplay between osteoporosis, dementia and fragility fractures Carmelinda Ruggiero
- Reducing falls and fractures by medication optimisation Lotta Seppala

09:00 - 10:30 - Auditorium 1
SCIENTIFIC SESSION IV
Chairpersons: Fitnat Dincer, Vladimir Palicka

09:00 **Plenary Lecture**
En route to a global sarcopenia consensus
Alfonso Cruz Jentoft

09:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

09:30 **OC19** HIGH MORTALITY IN OLDER MEN WITH LOW MUSCLE MASS AND STRENGTH – THE PROSPECTIVE STRAMBO STUDY
Presenting author: P. Szulc
Authors: R. Chapurlat

09:40 **OC20** LOWER INTRINSIC CAPACITY AND SARCOPENIA DATA FROM THE GEELONG OSTEOPOROSIS STUDY
Presenting author: K. L. Holloway-Kew
Authors: L. Stuart, K. B. Anderson, J. Pasco, E. C. Emma, L. J. Williams

09:50 **OC21** INCREASED DIETARY FIBER INTAKE IS ASSOCIATED WITH BETTER GRIP STRENGTH AND PHYSICAL PERFORMANCE IN COMMUNITY-DWELLING OLDER ADULTS
Presenting author: L. Lapauw
Authors: N. Amini, L. Peeters, M. Derrien, J. Raes, E. Gielen, J. Dupont

10:00 **OC22** EFFECT OF DALCROZE EURHYTHMICS EXERCISE ON MUSCLE, PHYSICAL AND COGNITIVE FUNCTION, AND FALLS IN SARCOPENIC OLDER ADULTS THE SARCARE RANDOMIZED CONTROLLED TRIAL
Presenting author: A. Trombetti
Authors: A. Tahar, F. Herrmann, C. Graf, T. Chevalley, R. Rizzoli, M. Hars

10:10 **OC23** IDENTIFICATION OF FACTORS ASSOCIATED WITH NON-RESPONSE TO A MULTICOMPONENT INTERVENTION IN OLDER ADULTS WITH PHYSICAL FRAILTY AND SARCOPENIA
Presenting author: R. Calvani
Authors: E. Marzetti, A. E. Nuzzi, A. Álvarez-Bustos, H. J. Coelho Júnior, S. Cacciatore, M. Tosato, F. Landi

10:20 **Presentation of the ESCEO-IOF Pierre Meunier Young Scientist Award** René Rizzoli

10:30 - 12:15 - Auditorium 1
SCIENTIFIC SESSION V
Chairpersons: Manju Chandran, Karel Pavelka

10:30 **Presentation of the IOF Olof Johnell Science Award** Nicholas C. Harvey

10:35 **Presentation of the ESCEO-IOF Young Investigator Awards** Jean-Yves Reginster, Nicholas C. Harvey

10:40 **Presentation of the ESCEO-Aging Clinical and Experimental Research Award** Nicola Veronese, Jean-Yves Reginster

10:45 **Plenary Lecture**
Nutritional strategies for optimal muscle health
Bess Dawson-Hughes

11:15 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

11:15 **OC24** CAN AI-DERIVED BMD FROM ROUTINE RADIOGRAPHS PREDICT FRACTURE RISK? A 6-YEAR FOLLOW-UP STUDY
Presenting author: J.-Y. Hsu
Authors: S.-H. Fu, T.-H. Tseng, C.-C. Hung, P.-C. Tsao, G. H. Chang, C.-Y. Wang

11:25 **OC25** FOREARM BMD IS A FRAX INDEPENDENT PREDICTOR OF FRACTURE RISK
Presenting author: E. McCloskey
Authors: H. Johansson, N. C. Harvey, M. Lorentzon, W. Leslie, J. Kanis

11:35 **OC26** PREDICTION OF INCIDENT FRACTURES USING THE AI-BASED TBS REVEAL BONE FRAGILITY INDEX A BAYESIAN SURVIVAL ANALYSIS
Presenting author: G. Gatineau
Authors: P. Eghbalishamsabadi, M. De Gruttola, K. Hind, M. Davies, A. Walstra, D. Krueger, N. Binkley, O. Suhail Alsaed, S. Alemadi, D. Hans

11:45 **OC27** 3D-SHAPER DIFFERENTIATION OF CORTICAL AND TRABECULAR BONE DESCRIBES FRACTURE STATUS IN PATIENTS WITH KIDNEY DISEASE
Presenting author: T. Nickolas
Authors: H. El-Bilbeisi, T. Kotzur, M. A. Aponte, M. Hussain, M. Balogun, M. Mohseni, L. Humbert, M. Bracco

11:55 **OC28** PERFORMANCE OF NOGG GUIDELINES BASED ON FRAX PRIOR TO DXA VS FRAX CALCULATED USING A FEMORAL NECK ESTIMATE FROM AN OPPORTUNISTIC SCREEN OF LOW BONE DENSITY FROM STANDARD X-RAY
Presenting author: C. Syme
Authors: M. D. Cicero, M. Lopes, A. Bilbily

12:05 **OC29** SUPERIOR FRAGILITY FRACTURE DISCRIMINATION BY CORTICAL ULTRASOUND SPECTROSCOPY COMPARED WITH BONE MINERAL DENSITY IN WOMEN AND MEN
Presenting author: K. Raum
Authors: G. Armbrecht, E. Wiebe

12:15 - 13:45 - Auditorium 1
SPONSORED SATELLITE SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

12:15 - 13:45 - Auditorium 2
SPONSORED SATELLITE SYMPOSIUM
See details on the Sponsored Sessions Section (Pages 28-29)

14:00 - 15:00
MEET-THE-EXPERT SESSION

MR - D9 **Screening for high fracture risk** Eugene McCloskey
MR - D8 **Rare bone diseases for the osteoporosis physician** Maria Luisa Brandi
MR - D1 **Meta-analysis: makings sense of umbrella and network approaches** Charlotte Beaudart
MR - D2 **Exercise: what to recommend in osteoporosis** Olivier Bruyère, Daniel Pinto

14:00 - 15:00 - Podium
ORAL PRESENTATIONS OF SELECTED POSTERS
Chairperson: Elaine Dennison

14:00 **OP11 - P1094** WHAT PROPORTION OF WOMEN EXPERIENCE SIGNIFICANT TRANSMENOPAUSAL BONE LOSS?
Presenting author: M. McClung
Author: A. Clark

14:06 **OP12 - P1496** APPLICATION OF MACHINE LEARNING MODELS FOR OSTEOPOROSIS SCREENING BUSHEHR ELDERLY HEALTH (BEH) PROGRAM
Presenting author: A. Razi
Authors: A. Shahsavand, S. Forghani A. Dadras, S. Nayebirad, A. Razi, K. Khalagi, N. Fahimfar, G. Shafiee, M. Sanjari, I. Nabipour, B. Larijani, H. Kavoosi

14:12 **OP13 - P1702** HOW COMMON IS IT? HIGH AND VERY HIGH-RISK FRACTURE RATES AMONG PATIENTS WITH A NON-OSTEOPOROTIC-RANGE BONE MINERAL DENSITY IN A DXA DATABASE FROM A TERTIARY MEDICAL CENTER
Presenting author: Y. Eden-Friedman
Authors: I. Vered, N. Tripto, N. Minsky, Y. Levy-Shraga, P. Rotman-Pikielny, L. Tripto-Shkolnik

14:18 **OP14 - P807** SERUM PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS) AND BONE MINERAL DENSITY IN NORWEGIAN ADOLESCENTS SEX-SPECIFIC ASSOCIATIONS AND MIXTURE EFFECTS
Presenting author: J. Wang
Authors: M. Averina, S. Huber, G. Grimnes, G. Fosse, Å. Bjørnerem, E. Evensen, J. Johansson, R. Joakimsen

14:24 **OP15 - P1370** MATERNAL DIABETES IN PREGNANCY AND FRACTURE RISK IN OFFSPRING A VICTORIA STATE-WIDE DATA LINKAGE STUDY
Presenting author: P. N. Che
Authors: M. Breslin, M. Thompson, M. Dalton, F. Johnston, L. S. Lieke

14:30 **OP16 - P527** SEX- AND DISTRIBUTION-SPECIFIC PROSPECTIVE MUSCLE-FAT-FRACTURE RELATIONSHIPS IN UK BIOBANK
Presenting author: E. Curtis
Authors: S. X. Lin, S. D'Angelo, L. Westbury, R. Moon, C. Cooper, K. A. Ward, N. C. Harvey

14:36 **OP17 - P735** THE LANDSCAPE OF RENAL OSTEODYSTROPHY IN EUROPE A FIRST REPORT FROM THE EUROD BONE BIOPSY DATABASE
Presenting author: I. Ystrøm
Authors: S. Salam, G. Spasovski, A. Ferreira, A. C. Ferreira, S. Keronen, H. Kröger, P. Evenepoel, H. S. Jørgensen

14:42 **OP18 - P1437** LONG-TERM QUALITY OF LIFE TRAJECTORIES IN FIBROUS DYSPLASIA AND MCCUNE-ALBRIGHT SYNDROME
Presenting author: R. Vijjhalwar
Authors: F. Clemeno, M. A. Legrand, R. Pinedo-Villanueva, M. K. Javaid

14:48 **OP19 - P500** IMPAIRED ORAL HEALTH PREDICTS FRACTURES AND FALLS IN OLDER ADULTS A PROSPECTIVE COHORT STUDY
Presenting author: E. Biver
Authors: A. Kada, N. Chebib, M. Papageorgiou, M. Hars, M. Hars, A. Trombetti, S. Ferrari, F. Müller

14:54 **OP20 - P849** THE SINTER STUDY A RECALL-BY-GENOTYPE DESIGN WITH MULTIDIMENSIONAL MUSCULOSKELETAL PHENOTYPING ACROSS INTERNAL-MEDICINE OUTPATIENT CLINICS
Presenting author: K. Huininga
Authors: F. Koromani, S. Li, K. Trajanoska, K. Berk, M. Boon, L. Chaker, P. van Daele, J. Hofland, M. van Hoek, M. Hemmelder, J. Roeters van Lennep, M. Medici, J. Olieman, B. Ozcan, R. Peters, F. Mattace-Raso, E. Mulugeta, E. F. C. van Rossum, J. van Rooij, A. Uitterlinden, W. Visser, E. F. van Velsen, M. C. Zillikens, F. Rivadeneira

15:00 **OP21 - P586** DEVELOPMENT AND EXPERT VALIDATION OF AN INTERNATIONAL POSTMENOPAUSAL OSTEOPOROSIS RISK ASSESSMENT AND LIFESTYLE (IPORL) QUESTIONNAIRE
Presenting author: F. Alradini
Author: A. Alblooshi

15:06 **OP22 - P386** FRACTURES AND BONE MINERAL DENSITY LOSS IN ADULTS LIVING WITH HIV IN LOW- AND MIDDLE-INCOME COUNTRIES A SYSTEMATIC REVIEW AND META-ANALYSIS
Presenting author: C. Gregson
Authors: M. Westby, A. De Wilton, T. Madanhire, J. Savovic, G. Gwaze, M. Vitoria, J. Amuthavalli Thiyagarajan, K. A. Ward

14:00 - 15:00 - MR- D4
EDUCATIONAL LECTURE
CKD-Associated Osteoporosis: The Over-looked Burden of Bone Fragility in CKD
Chairperson: Maria Fusaro, Nicholas C. Harvey
- Denosumab use in advanced CKD patients: yes or no, this is the dilemma Maria Fusaro
- Mendelian randomization role of vitamin D in coronary heart disease Giovanni Tripepi
- Bone quality in CKD: How to assess and why it matters Hanne Skou Jørgensen
- KIDNEY-FRAX: Is it the right time to perform it? Jordi Bover

14:00 - 15:00 - MR - D3
ESCEO MEETS OARSI
Obesity and its implications for pain and structure in osteoarthritis
Chairpersons: Martin Englund, Jean-Yves Reginster
- The role of obesity and adipose tissue dysfunction in osteoarthritis pain Marie Binvignat
- Structural changes with weight loss in knee osteoarthritis Mikael Boesen

14:00 - 15:00 - MR - D12
ESCEO AND IOF MEET EUGMS
Integrating falls and fractures management in the patient-centered care
Chairpersons: Nathalie Van der Velde, Carmelinda Ruggiero, René Rizzoli
- Landscape for integrated falls and fragility fracture pathways across Europe: where do we stand? Nathalie Van der Velde
- Falls and fragility fractures in older adults with neurocognitive disorders: preparing for the impending storm Tahir Masud
- Integrating falls and fragility fractures secondary prevention: the small win of the orthogeriatric care pathway Maria Bonnici

15:00 - 16:45 - MR - D12
COMMITTEE OF SCIENTIFIC ADVISORS SPECIAL SESSION
Chairpersons: Eugene McCloskey, Etienne Cavalier

- Fragile Bone, Fragile Constructs? Bone Health Assessment and Osteoporosis Therapies in Spinal Fusion Manju Chandran
- PTH Analog Therapy in CKD G4-G5D: Current Evidence and Potential Role of Abaloparatide in Adynamic Bone Disease Maria Fusaro
- Crosstalk of bone and muscle in ageing Gustavo Duque

15:00 - 17:10 - Auditorium 1
SCIENTIFIC SESSION VI
Chairpersons: Claudia Campusano, Atsushi Suzuki

15:00 **Plenary Lecture**
State of the art: advances in osteoarthritis imaging Felix Eckstein

15:30 **ORAL COMMUNICATIONS SELECTED FROM ABSTRACTS**

15:30 **OC30** INFRAPATELLAR FAT PAD MORPHOLOGY AND SIGNAL PREDICTS KNEE REPLACEMENT RISK IN OSTEOARTHRITIS AN 8-YEAR MRI CASE-CONTROL STUDY
Presenting author: J.-P. Pelletier
Authors: P. Paiement, M. Dorais, J.-P. Raynauld, J. Martel-Pelletier

15:40 **OC31** QUANTIFYING TREATMENT-RELATED INFLAMMATORY CHANGE IN KNEE OSTEOARTHRITIS USING NORMALIZED MRI INFLAMMATION VOLUME (NORMI)
Presenting author: M. Clark
Authors: O. Kubassova, A. Singareddy, R. Hagoug, D. Skerrett

15:50 **OC32** FROM MODEL TO APPLICATION METABOLOMIC-DRIVEN MACHINE LEARNING FOR PROGNOSIS OF KNEE STRUCTURAL OSTEOARTHRITIS PROGRESSION
Presenting author: J. Martel-Pelletier
Authors: A. Jamshidi, G. Zhai, M. Liu, W. Zhang, G. Jones, F. M. Cicuttini, J.-P. Pelletier

16:00 **OC33 - TOWARDS OA PATIENTS ENDOTYPING** DEVELOPMENT OF AN LC-MS/MS METHOD FOR THE QUANTITATION OF JOINT-RELATED COLLAGENS FRAGMENTS
Presenting author: J. Demeuse
Authors: L. Kalut, A. Mackowiak, M. Piette, E. Grifnée, E. Cavalier

16:10 **OC34** INTRA-ARTICULAR POLYACRYLAMIDE HYDROGEL FOR KNEE OSTEOARTHRITIS 1-YEAR RESULTS FROM THE LUNA OBSERVATIONAL STUDY.
Presenting author: T. Klonschinski
Authors: A. Migliore, E. Fockens, P. Peev, P. Massin, J. Beier, S. Maimen, P. Drees, H. Henning

16:20 **OC35** EXPERT CONSENSUS ON HYALURONIC ACID INJECTIONS FOR KNEE OSTEOARTHRITIS A PATIENT-CENTERED APPROACH
Presenting author: A. Mobasheri
Authors: N. Fuggle, F. Rannou, E. Maheu, A. Migliore, N. Al-Daghri, M. Alokail, P. Ammann, F. Berenbaum, A. Botto-van Bemden, M. L. Brandi, N. Burlet, R. Chapurlat, C. Cooper, E. Dennison, N. C. Harvey, G.-I. Im, A. Kurth, R. Matijevic, D. Messina, J. Monfort Faure, R. P. Radermecker, R. Schmidmaier, S. Silverman, J. Wegrzyn, L. Zakraoui, R. Rizzoli, O. Bruyère, J.-Y. Reginster

16:30 **OC36** IS EFFUSION SYNOVITIS, ASSESSED QUANTITATIVELY BY MORPHOMETRY OR SEMI-QUANTITATIVELY BY EXPERT READING; RELATED TO OSTEOARTHRITIS PROGRESSION
Presenting author: F. Eckstein
Authors: K. Sheikhi Valashani, T. Winkler, J. Collins, F. Roemer, A. Guermazi, D. Hunter, W. Wirth

16:40 **Plenary Lecture**
Novel emerging therapies for osteoarthritis
Ida Haugen

17:10 - 18:10
NON-SPONSORED SYMPOSIA

MR - C1 **Narrowing the "Treatment Gap of Osteoporosis" Using the Optimal Clinical Paradigm**
Chairperson: P. Dean Cummings

- Closing the Care Gap: Defining a Scalable Pathway to Transform Bone Health Evaluation Across Health Systems Rachel Patel
- Integrating Biology, Behavior, Function, and Environment: A 4-Pillar Framework Driving Comprehensive Bone Health Optimization Nikos Koumontzis
- Mapping the Future: Using Structured Assessment to Guide Implementation, Direction, and Impact in Bone Health Care P. Dean Cummings

MR - D9 **Vitamin D Metabolite Ratio (VMR): From LC–MS/MS Technology to Clinical Decision-Making in Bone and Metabolic Health**
Chairpersons: Etienne Cavalier, Nasser M. Al-Daghri
- Analytical Principles and Performance Considerations in LC–MS/MS Profiling of Vitamin D Metabolites Etienne Cavalier
- Vitamin D Metabolite Ratio as a Functional Biomarker Across Health Outcomes Nasser M. Al-Daghri, Shaun Sabico
- Q&A

MR - D8 **Osteoporosis Diagnosis in Intellectual Disability**
Chairperson: Elena Bischoff
- The Importance of Bone Health Monitoring and Fracture Risk Prediction in Intellectual Disability: State of the Art Eilish Burke
- REMS Application in Individuals with Intellectual Disability Federica Saponaro

MR - D1 **Bridging Science and Service: Biomarkers, Translational Models, and Equity in Implementation in the Identification and Management of Sarcopenia and Frailty**
Chairpersons: Nicholas Fuggle, Manju Chandran
- The Global Leadership Initiative on Sarcopenia (GLIS): Defining a Pathway into the Medical Glossary Ben Kirk
- Integrating imaging biomarkers and biochemical markers of sarcopenia into frailty care pathways Ali Mobasheri
- Translating Research into Service: The "Frailty in Community" Program – From Science to Real-World Care Joyce McSwan
- Strengths-based approaches to frailty assessments in partnership with older Aboriginal and Torres Strait Islander adults Jesse Zanker

MR - D2 **From Bone Fragility to Fracture: Perspectives on Diagnosis and Prevention**
Chairperson: Nicola Veronese
- Fragility Fractures in Osteoporosis: Diagnostic Limitations and Early Prevention Strategies Elena Bischoff
- Improving Fracture Prevention Through Advanced Diagnostic Tools Nikola Kirilov
- Fracture Prevention in high-risk Patients: The Clinical Role of REMS Technology Giuseppe Guglielmi

MR - D3 **From Fracture to Function: A Dynamic Physiotherapy Pathway for Vertebral Fracture Recovery**
Chairperson: George Ioannidis
- Physical performance measures for the assessment of functional limitations in older adults with vertebral fractures Alexandra Papaioannou
- Applying and integrating clinical care pathways to guide personalized exercise prescriptions Bonny O'Hare

MR- D4 **Innovative HTA Approaches for Sarcopenia: From Economic Burden to Patient-Centered Value**
Chairperson: Mickael Hiligsmann
- The Economic Burden of Sarcopenia and Its Impact on Societal Costs and Quality of Life Olivier Bruyère
- Economic Evaluation and HTA Approaches to Assess Value in Sarcopenia Mickael Hiligsmann
- Listening the Voice of Participants in Sarcopenia Research Charlotte Beaudart

MR - D12 **Transforming Episode Accountability Model: An Opportunity to Drive Bone Health Optimization and Fracture Liaison Service Uptake in the United States**
Chairperson: Rita Roy
- Transforming Episode Accountability Model (TEAM): Impact on Orthopaedic, Spine, and Bone Health Clinical Practice and Opportunities to Drive Osteoporosis Diagnosis and Treatment Rita Roy
- A Spine Surgeon Perspective on the Need for Spine and Bone Health Optimization and Implementation of Fracture Liaison Service Programs Tom Schuler

08:00 - 09:00

NON-SPONSORED SYMPOSIA

MR - D9 **Nutrition and Physical Exercise: Individual Roles and Synergy in Sarcopenia Management**

Chairperson: Bernardo Abel Cedeño Veloz

- Molecular Mechanisms Underlying Sarcopenia: From Basic Research to Clinical Implications Marta Montes Resano
- Nutritional Strategies for Managing Sarcopenia Bernardo Abel Cedeño Veloz
- Integrating Nutrition and Exercise: A Synergistic Approach Chenhui Chen
- Discussion + Q&A

MR - D8 **Lipoprotein (a): New evidence for Bone-Vascular axis in Osteoporosis and Atherosclerosis**

Chairperson: Sekib Sokolovic

OP1 - P416

FROM WRIST TO HIP: CAN EARLY FLS INTERVENTION AFTER A DISTAL RADIUS FRACTURE PREVENT THE NEXT FRAGILITY FRACTURE

A. E. Elsalamwy[1], D. C. Charchoglyan[2], S. Z. Zidan[3], C. S. Singh[1]

[1]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-sea, United Kingdom; [2]Emergency Department, Southend on sea, United Kingdom; [3]Trauma & Orthopaedic Department, North Middlesex University Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom

Background

Distal radius fracture (DRF) is frequently the first clinical manifestation of osteoporosis and a strong predictor of future major fragility fractures, particularly hip fractures. The risk of a subsequent hip fracture is reported to be **1.4–3.5 times higher** following a DRF, with the majority occurring within two years. This "imminent risk" period represents a key opportunity for secondary prevention. Despite NICE and Royal Osteoporosis Society (ROS) guidance, many patients with DRF are not referred for bone health assessment. The Fracture Liaison Service (FLS) model provides a structured approach for identification, investigation, and treatment. We evaluated whether FLS-led management following DRF at Southend University Hospital reduced the risk of subsequent hip and other fragility fractures.

Methods

We retrospectively reviewed all adults aged ≥50 years presenting with an index DRF between January 2018 and December 2024. Patients were stratified into:

(1) **FLS group:** completed FLS pathway (assessment ≤90 days, DXA scan, initiation of anti-osteoporosis therapy, and falls assessment).

(2) **Non-FLS group:** no referral or incomplete pathway.

The primary outcome was hospital admission with a hip fracture within 24 months. Secondary outcomes included any new major osteoporotic fracture and treatment adherence. Kaplan–Meier survival analysis and multivariable Cox regression were used to estimate hazard ratios (HR) adjusted for age, sex, comorbidities, and previous fractures.

Results

Among **612 eligible patients** (mean age 72 ± 10 years; 78% female), **48%** received full FLS follow-up. Over 24 months, **15.6%** of the non-FLS group sustained a second fragility fracture compared with **8.9%** in the FLS group. Hip fractures occurred in **5.1% vs 2.4%**, respectively. FLS management was associated with a **34% lower hazard** of any secondary fracture (adjusted HR 0.66; 95% CI 0.48–0.91; p = 0.01).

Conclusions

Patients presenting with a distal radius fracture face a high imminent risk of subsequent hip or major fragility fractures. Comprehensive post-fracture management through an FLS pathway significantly reduced secondary fracture rates within two years. These findings reinforce the value of universal FLS coverage and early bone-health optimisation to transform the distal radius fracture from a precursor to a preventable event in the fracture-care continuum.

ASSOCIATION BETWEEN THE TREATMENT-RELATED CHANGE IN BONE MINERAL DENSITY AND FRACTURE RISK REDUCTION ACCORDING TO THE PRE-TREATMENT BMD: ANALYSIS FROM THE FNIH-ASBMR SABRE PROJECT

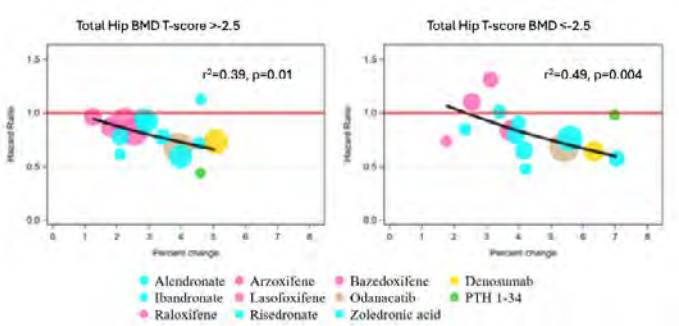
M. Schini[1], L. Lui[2], T. Vilaca[3], S. K. Ewing[4], A. Thompson[4], B. L. Langdahl[5], D. M. Black[4], M. L. Bouxsein[6], R. Eastell[1]

[1]The University of Sheffield, SHEFFIELD, United Kingdom; [2]Research Institute, California Pacific Medical Center, San Francisco, United States; [3]The University of Sheffield, Sheffield, United Kingdom; [4]Department of Epidemiology & Biostatistics, University of California, San Francisco, United States; [5]Department of Clinical Medicine, Department of Endocrinology and Internal Medicine, Aarhus University, Aarhus, Denmark; [6]Center for Advanced Orthopedic Studies, Beth Israel Deaconess Medical Center and Department of Orthopedic Surgery, Harvard Medical School, Boston, United States

Objective

In December 2025, the FDA has qualified the use of total hip BMD (TH BMD) as a surrogate endpoint for future trials of anti-osteoporosis therapies. This was based on analyses and evidence from the FNIH-ASBMR SABRE (Study to Advance BMD as a Regulatory Endpoint) project. However, if future trials do not have to demonstrate anti-fracture efficacy, they may enrol lower-risk subjects. Thus, it is essential to determine whether baseline BMD levels affect the relationship between changes in TH BMD and fracture risk reduction.

Methods



Using the SABRE database, we separated participants into those with a TH BMD T-score ≤ -2.5 and those with a TH BMD T-score> -2.5. We performed trial-level meta-regressions comparing the association between the 24-month between-treatment difference in TH BMD per cent change and clinical fracture risk reduction across baseline TH BMD T-score subgroups. We calculated the r^2 (95% CI) for each group. The clinical fracture category was defined as non-vertebral + clinical vertebral fractures.

Results

Data from 15 trials were included in the meta-regression. There were 20,474 participants in the T-score ≤ -2.5 group and 54,196 in the T-score > -2.5 group. The meta-regression results were similar across groups, with r^2 (95% CI) for the T-score ≤ -2.5 group of 0.49 (0.08 to 0.70), p = 0.004, and for the T-score > -2.5 group, r^2 = 0.39 (0.02 to 0.64), p = 0.01. The p value for the r^2 interaction term was 0.66.

Conclusion

Notably, the range of BMD per cent change was greater in the low-BMD group. This was because the results were expressed as a percentage, however, the absolute changes in BMD were similar. The higher BMD group had more trials from less potent medications. These findings suggest that, in future trials of new osteoporosis treatments where efficacy will be judged by total hip BMD change, participants can be included independently of their baseline total hip T-score, as the association between bone mineral density per cent change and fracture risk reduction is similar.

OP3 - P1770

REAL-WORLD TREATMENT STRATEGIES FOR OSTEOPOROSIS IN OLDER ADULTS WITH CKD-MBD: IMPACT OF GERIATRIC SYNDROMES AND TREATMENT COMPLIANCE

Z. Şahin Tırnova[1], E. Pınar[1], Z. Fetullahoğlu[1], D. Seyithanoğlu[1], H. Arıcı[1], T. Erdoğan[1], S. Öztürk[2], O. Soyluk Selçukbiricik[3], G. Yenidünya Yalın[3], N. Gül[3], A. S. Artan[2], M. A. Karan[1], G. Bahat[1]

[1]Istanbul University Faculty of Medicine, Geriatrics, Istanbul, Türkiye; [2]Istanbul University Faculty of Medicine, Nephrology, Istanbul, Türkiye; [3]Istanbul University Faculty of Medicine, Endocrinology, Istanbul , Türkiye

Aim: Osteoporosis (OP) management in chronic kidney disease (CKD) is complicated by altered bone turnover, mineral metabolism, renal drug clearance, and coexisting geriatric syndromes. Frailty and high fall risk may justify treatment even without low T-scores. This study presents a real-world, multidisciplinary, and individualized approach to managing older adults with OP and CKD–mineral bone disease (MBD), focusing on geriatric syndromes and treatment compliance (access, duration, adverse effects).

Participants and Methods: Twenty older adults with OP and stage 3a–5 CKD were evaluated by a multidisciplinary team. Baseline data (December 2023) included clinical, DXA, biochemical, and comprehensive geriatric assessment(CGA) findings; fracture and treatment history; inappropriate medication use(IMU); and fall-risk-increasing drugs (FRIDs). Patients were categorized as OP-only, OP + adynamic bone disease(ABD), or OP + osteomalacia(OM). Treatment was individualized based on bone turnover, renal function, prior therapy, and CGA. Compliance was reassessed at two years (December 2025).

Results: Median age was 78 years; 45% were male. Frailty was present in 50%, orthostatic hypotension in 50%, falls in 35%, and polypharmacy in 95% (median 9 drugs). IMU was identified in 12(60%) of patients, with 1–3 inappropriate drugs deprescribed per patient, and FRIDs were used by 75%. Malnutrition was present in 25%. Prior fragility fractures were common (65%), yet only two patients were on OP treatment at baseline. Diagnosis, treatment decisions, and compliance are summarized in Table 1. At two years, 50% patients were fully compliant, 30% required treatment modification (reimbursement issues, comorbidities, or switching/interruptions), 10% were lost to follow-up, and 10% were managed conservatively. No severe hypocalcemia, new fragility fractures, or adverse-effect–related discontinuations occurred.

Conclusions: Managing osteoporosis in older adults with CKD requires a nuanced, patient-specific strategy supported by multidisciplinary collaboration, considering bone turnover, renal impairment, and complex geriatric syndromes. Treatment compliance remains crucial; in our cohort, reimbursement delays and comorbidities were the main barriers. Overall, denosumab—combined with structured calcium supplementation and monitoring—appeared to be the most feasible therapeutic option.

Table-4: Diagnosis, Treatment Decisions, Duration and Compliance Outcomes of the Study Patient

Patient Number	Diagnosis	Decision	Treatment Compliance	Treatment Duration (months)
1	CKD-MBD (ABD) + OP	Teriparatide	Lost to follow-up	-
2	CKD-MBD (ABD) + OP	Teriparatide after discontinuation of vit D and calcium	Could not start teriparatide (reimbursement issues); switched to denosumab	18
3	OP-only	Oral bisphosphonate therapy continued	Compliant, no complications	28
4	OP-only	Zoledronate	Compliant, no complications	21

5	CKD-MBD (ABD) + OP	Teriparatide after discontinuation of active vitamin D and phosphate binders	Compliant, no complications	18
6	CKD-MBD (ABD) + OP	Follow-up without treatment (Due to no indication) Cessation of active vitamin D and calcium	Follow-up without treatment	-
7	OP-only	Romosozumab	Compliant, no complications	12 mo romosozumab, followed by denosumab
8	OP-only	Romosozumab	Irregular romosozumab use, later switched to denosumab	10 months irregular romosozumab, then switched to denosumab
9	OP-only	Denosumab + Testosterone replacement	Compliant, no complications	17
10	OP-only	Teriparatide	Could not initiate teriparatide due to recurrent hospitalizations (GI bleeding, ileus); later switched to denosumab	7
11	OP-only	Denosumab	Compliant, no complications	18
12	OP-only	Denosumab	Lost to follow-up	-
13	CKD-MBD (ABD) + OP	Teriparatide	Compliant, no complications	24 months teriparatide, followed by denosumab
14	CKD-MBD (ABD) + OP	Teriparatide	Compliant, no complications	10
15	CKD-MBD (ABD) + OP	Denosumab, after discontinuation of calcium and no evidence of ABD	Compliant, no complications	10
16	CKD-MBD (OM) + OP	Denosumab after calcium and vitamin D supplementation	Interrupted after 2nd denosumab dose (1-year gap), later resumed therapy	19 months (with interruption)
17	OP-only	Follow-up without treatment (Due to low life expectancy and being bedridden)	Follow-up without treatment	-
18	CKD-MBD (OM) + OP	Teriparatide after vitamin D supplementation	Could not start teriparatide (recurrent UTIs/urosepsis) then refused further treatment	-
19	CKD-MBD (OM) + OP	Denosumab after vitamin D supplementation	Delayed denosumab initiation due to cardiac problems; sustained fracture during delay, denosumab later started	3
20	OP-only	Denosumab	Compliant, no complications	3

ABD: Adynamic Bone Disease, CKD-MBD: Chronic Kidney Disease – Mineral and Bone Disorder, OM: Osteomalacia, OP: Osteoporosis, UTI: Urinary Tract Infection, GI: Gastrointestinal

GLP-1 RECEPTOR AGONISTS AND MUSCULOSKELETAL OUTCOMES: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

C. Beaudart[1], Y. Malréchauffé[1], S. van Heden[1], D. Sanchez-Rodriguez[2], A. Scheen[3], O. Bruyère[4], A. Mobasheri[5], G. Duque[6], R. Rizzoli[7], J.-Y. Reginster[8]

[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), Research Institute for Life Sciences (NARILIS), University of Namur, Namur, Belgium; [2]Department of Geriatrics, Brugmann University Hospital, Université Libre de Bruxelles, Bruxelles, Belgium; [3]Division of Diabetes, Nutrition and Metabolic Disorders, Department of Medicine, CHU Liège, Liège, Belgium; [4]Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium; [5]Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; [6]Bone, Muscle & Geroscience Group, Research Institute of the McGill University Health Centre, Montréal, Canada; [7]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland; [8]Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia

Introduction: This systematic review/meta-analysis aims to synthesize clinical data on the effects of Glucagon-like peptide-1 (GLP-1) receptor agonists (RAs) on key relevant bone, muscle, and joint outcomes. The primary objective is to establish whether these agents are safe for the musculoskeletal system; secondarily, the study examines their potential protective role in mitigating age- and disease-related decline and in improving some key relevant outcomes in musculoskeletal health.

Methods: MEDLINE, Cochrane Central Register of Controlled Trials (CENTRAL) (both via Ovid® platform) and Embase were searched in March 2025 to identify relevant randomized controlled trials (RCTs) or real-world evidence (RWE) studies to be included. This bibliographic search was completed with manual search. A random-effect model meta-analysis was performed for any outcome reported in at least 2 studies. Subgroup analyses were performed on the type of GLP-1 RAs, type of comparator used and study design. Sensitivity analyses were performed to test the robustness of the data. This work has been performed in adherence with PRISMA statement. (PROSPERO Record ID: CRD420251024082).

Results: From 1,148 potentially relevant references, 61 articles (47 RCTs, 13 RWE studies and 1 pharmacovigilance study, combining a total of 1,250,778 individuals) met the inclusion criteria. Different GLP1-RAs were represented across the panel of studies i.e., semaglutide, liraglutide, exenatide, dulaglutide, and tirzepatide (dual agonist GIP/GLP-1), as well as others such as albiglutide, lixisenatide, and SAR425899 (bamadutide). No effect on bone outcomes (i.e., bone mineral density (all sites) and fractures (all sites) were observed when models included the most adjusted effect size. Regarding muscle outcomes, a significant decrease of lean body mass/fat-free mass was consistently observed with GLP1-RAs in the global model (k=28, SMD0.52, 95%CI -0.8; -0.23, I^2 88%, p-value for heterogeneity <0.0001), which remained robust in all sensitivity analyses. Subgroup analyses showed that the effect was mainly driven by liraglutide and semaglutide, with a decrease in lean body mass/fat-free mass observed when GLP-1 RAs were compared with placebo. No publication bias was found. Regarding joint outcome, models revealed no significant change in WOMAC pain, physical function and stiffness.

Conclusion: This meta-analysis is the first to investigate the effects of GLP-1 RAs on a large panel of musculoskeletal health outcomes. While no effect on bone outcomes and joint outcomes was found, effects on muscle mass outcomes (i.e., decrease of lean body mass/fat-free mass) were observed, apparently in line with body weight reduction. The clinical relevance of these results needs to be firmly established. Further studies in this field, including those looking at muscle function and using multivariate models considering confounding are needed to better reinforce the models and final findings.

OP5 - P1076

BISPHOSPHONATES OR DENOSUMAB AFTER FRACTURE? REAL-WORLD EVIDENCE FROM A TARGET TRIAL EMULATION IN MULTIMORBID ADULTS

M. Lin[1,2,3], T. Tran[1,4], R. Blank[1,5], J. R. Center[1,2,6], D. Bliuc[1,7]

[1]Bone Epidemiology, Clinical and Translation Science Lab, Garvan Institute of Medical Research, Darlinghurst, Australia; [2]St Vincent's Clinical School, Faculty of Medicine and Health UNSW, Darlinghurst, Australia; [3]Department of Endocrinology, Royal Prince Alfred Hospital, Camperdown, Australia; [4]School of Medical Engineering, University of Technology, Ultimo, Australia; [5]Medical College of Wisconsin, Milwaukee, United States; [6]Department of Endocrinology, St Vincent's Hospital, Camperdown, Australia; [7]North Wales Medical School, Bangor University, Wales, United Kingdom

Objective: Individuals with multimorbidity (MM) are often excluded from randomised trials, limiting evidence on comparative effectiveness of antiresorptive therapies. We implemented target trial emulation (TTE) to compare bisphosphonates (BP) versus denosumab (Dmab) for refracture and all-cause mortality across MM clusters.

Methods: Using whole-population linked administrative data, we identified treatment-naïve adults aged ≥50 years in New South Wales, Australia, who sustained fractures requiring emergency or hospital admission between 2010 and 2018. We excluded individuals with prior osteoporosis treatment, prior fractures, metastatic cancer, or other metabolic bone disorders. A clone-censor-weight approach compared two strategies: initiation of BP (alendronate, risedronate, or zoledronic acid) versus Dmab within

12 months post-fracture (grace period). Time zero was the fracture date, with follow-up of up to 4 years for refracture and mortality. Individuals were cloned, assigned to each strategy, and censored if their observed treatment deviated from the assigned strategy. Inverse probability of censoring weights addressed informative censoring. Latent class analysis (LCA) classified individuals into MM clusters based on comorbidities at time of fracture. Sex-specific weighted pooled logistic regression estimated hazard ratios (HRs) and 4-year risk differences (RDs).

Results: Among 117,031 eligible individuals (mean age 75.7 years; 64% women), 6036 initiated BP and 2611 initiated Dmab within grace period. LCA identified four MM clusters (cardiovascular, cardiometabolic, geriatric, mental health; median comorbidity count: 4-12) and one low MM cluster (median: 0). Compared with Dmab, BP use was associated with lower all-cause mortality in women (HR 0.71, 95% CI 0.67–0.76; RD −26.3%, 95% CI −31.1% to −21.1%) and men (HR 0.79, 95% CI 0.74–0.85; RD −24.4%, 95% CI −30.6% to −17.9%). Mortality reduction was consistent across multimorbidity clusters. Refracture risk was comparable between treatment groups.

Conclusion: In this real-world TTE, initiation of BP after fracture was associated with lower mortality compared to Dmab in both healthy and MM populations, with comparable refracture risk. These findings suggest BP have non-skeletal benefits that warrant further investigation.

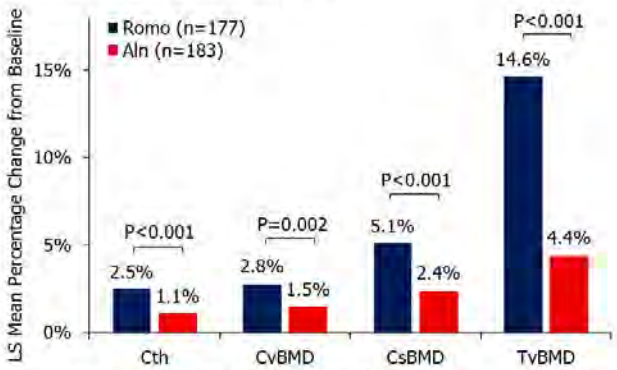
OP6 - P806

HIP BONE COMPARTMENT RESPONSES TO ROMOSOZUMAB VERSUS ALENDRONATE IN PATIENTS WITH DIABETES: A SUBGROUP ANALYSIS FROM THE ARCH TRIAL USING 3D-DXA MODELLING

S. Ferrari[1], N. Napoli[2], B. L. Langdahl[3,4], K. Luijtens[5], J. Timoshanko[6], L. Humbert[7], M. Bracco[7]

[1]University Hospital of Geneva, Division of Bone Diseases, Geneva, Switzerland; [2]University of Rome, Unit of Endocrinology and Diabetes Campus Bio-Medico, Rome, Italy; [3]Aarhus University, Department of Endocrinology, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [5]UCB, Brussels, Belgium; [6]UCB, Slough, United Kingdom; [7]3D-SHAPER Medical, Barcelona, Spain

Objective(s): Type 2 diabetes mellitus (T2DM) is linked to increased fracture risk.[1] The paradox of preserved bone mineral density (BMD) and trabecular bone structure but impaired cortical bone parameters in T2DM underscores the importance of advanced imaging for fracture risk assessment. We sought to evaluate changes in hip bone parameters with romosozumab (Romo) versus alendronate (Aln) in postmenopausal women with osteoporosis (OP) and T2DM.



Materials and Methods: In ARCH (NCT01631214)[2], postmenopausal women with OP were randomised to monthly subcutaneous Romo (210 mg) or weekly oral Aln (70 mg) for 12 months (blinded). We analysed a subset of 360 women (Romo: n=177; Aln: n=183) who had T2DM at baseline and total hip Dual-Energy X-ray Absorptiometry (DXA) scans available. Cortical thickness (Cth), cortical volumetric BMD (CvBMD), cortical surface BMD (CsBMD) and trabecular volumetric BMD (TvBMD) estimates were obtained with 3DShaper Research software (v2.14, 3D-Shaper Medical, Barcelona, Spain). Percentage changes from baseline to Month 12 between treatments were assessed using an ANCOVA model adjusted for baseline covariates.

Results: Baseline characteristics, including mean (standard deviation) age (Romo: 75.8 [7.2] vs Aln: 75.5 [6.9] years), prevalence of severe vertebral fracture (66% vs 62%, respectively) and total hip areal BMD (0.659 [0.087] vs 0.651 [0.085] g/cm^2, respectively) were comparable between groups and generally consistent with overall ARCH populations.[2] At Month 12, Romo resulted in greater increases in all hip compartment-specific parameters vs Aln (least squares mean difference in cortical parameters: 1.3–2.7%; TvBMD: 10.2%; **Figure**).

Conclusions: In postmenopausal women with OP and T2DM, Romo demonstrated greater hip structural and density improvements vs Aln. The magnitude and pattern of these responses in the T2DM subgroup were consistent with the overall ARCH population.[3] Thus, T2DM did not attenuate the clinical efficacy of Romo.

Objectives:

Recently, initial use of osteoanabolic agents is recommended in goal-directed treatment algorithms for patients at very high fracture risk (VHFR). Although FLS and Osteoporosis Liaison Service (OLS) have been established to improve the osteoporosis management, the effectiveness of these intensive care programs which integrate osteoanabolic therapies has not been established. We designed a clinical trial to investigate the effectiveness of intensive care (FLS-CARE) aligned with the goal-directed osteoporosis treatment compared with usual care in patients at VHFR.

Methods and Analysis:

Japanese Osteoporosis Intervention Trial-08 (JOINT-08), a multi-center, site classification into two groups, on-going intervention study, involves postmenopausal Japanese women at VHFR aged 55 and older, defined by any of: bone mineral density (BMD) T-score < -3.3, two or more prevalent vertebral fractures, at least one semi-quantitative (SQ) grade 3, one or more fragility fractures with BMD T-score < -2.5, or a prevalent hip fragility fracture.

The patients in FLS-CARE group are registered at medical institutions with a Japan Osteoporosis Society-certified physician and OLS manager and receive an intensive care program integrating goal-directed osteoporosis treatment and FLS/OLS support (education on osteoporosis and treatment management). Patients in the control (PCP-CARE) group receive standard care at the discretion of their primary care physician.

The primary endpoint of this study is the incidence of morphometric vertebral fractures by SQ grade at 12 months, and the key secondary endpoint is the incidence of morphometric vertebral fractures at 24 months. The other secondary end points are adherence, persistence, incidence of non-vertebral fractures, incidence of worsening of vertebral fracture by SQ grade, changes in BMD at lumbar spine, femoral neck, and total hip at 12 months as well as descriptive analyses of adverse events.

Conclusion:

JOINT-08 is the first study to investigate the effectiveness of an intensive care program, combining goal-directed osteoporosis treatment and patient management by an OLS manager in postmenopausal osteoporosis at VHFR. The findings will be crucial for advancing treatment strategies to prevent osteoporotic fractures.

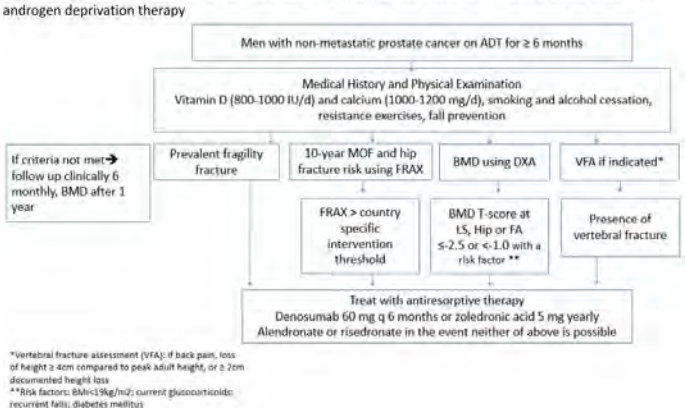
of Medicine, Foggia, Italy, Foggia, Italy; [16]Medical University of Vienna, Vienna, Austria; [17]Stellenbosch University, Western Cape, South Africa, Panorama, South Africa; [18]International Osteoporosis Foundation, Nyon, Switzerland; [19]Geneva University Hospitals, Geneva, Switzerland

Objective



Androgen deprivation therapy (ADT) induces bone loss and significantly increases fracture risk in non-metastatic prostate cancer (nmPCa). Our aim is to provide physicians an evidence-based and practical guidance on the approach to bone health management in patients with nmPCa on ADT.

Material and Methods

The International Osteoporosis Foundation- Bone and Cancer Working Group (BCWG) members agreed on evaluating a set of 7 clinical questions. We addressed each question based on the evidence retrieved from 2 systematic reviews, including original studies and guidelines that aimed to optimize bone health in patients with nmPCa on ADT (CRD42021225502; CRD420251013073). The BCWG members voted anonymously on each question on answer.forms app, using strongly agree (SA), weakly agree (WA), weakly disagree (WD), strongly disagree (SD), not qualified (NQ).

Results

Figure: Suggested approach to bone health management in patients with non-metastatic prostate cancer on androgen deprivation therapy

Patients with nmPCa on ADT should be assessed for a previous fragility fracture (100%SA), and have a bone mineral density (BMD) and a fracture risk assessment upon the initiation of ADT (87%SA, 13%WA). A calcium intake of 1000-1200 mg/d (86%SA; 14%WA) and vitamin D supplementation of 800-2000 IU/d (71%SA; 29%WA) are required. A bone active agent is recommended for a previous fragility fracture (93%SA; 7%WA), a 10-year fracture risk above the country specific intervention threshold (80%SA;20%WA) or a BMD T-score at the lumbar spine, total hip, femoral neck or forearm ≤ -2.5, or ≤ -1 in the presence of one or more risk factors (53%SA; 34%WA; 13% WD). First line treatment options are Denosumab 60mg every 6 months (as it reduces radiologic vertebral fractures by 85% at 1 year, versus placebo) or Zoledronic acid 5mg yearly (as it increases BMD by 6.9% at lumbar spine, versus placebo) (87%SA; 13%WA) (Figure).

Conclusion

ADT increases osteoporosis risk. Bone health in patients with nmPCa should be prioritized. Screening and early intervention following our simple and practical approach allow to reduce fracture and its related morbidity. Strategies to improve guidelines implementation, increase physician and patient awareness, and investigation of the cost effectiveness of our approach are needed to close the bone health care gap.

OP9 - P427

OSTEOPOROSIS AND HEARING LOSS: NATIONWIDE EVIDENCE FOR AN EXTRA-SKELETAL PROTECTIVE EFFECT OF ZOLEDRONIC ACID AND DENOSUMAB

C.-F. Huang[1], S.-H. Hung[2], W. P. Chan[3]

[1]Department of Family Medicine, Chi Mei Medical Center, Tainan City, Taiwan; [2]Department of Otolaryngology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [3]Department of Radiology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Objective

To investigate the association between osteoporosis or fragility fractures and the risk of hearing loss, and to evaluate whether long-acting injectable osteoporosis treatments, specifically zoledronic acid and denosumab, are associated with a reduced risk of hearing loss.

Material and Methods

This nationwide retrospective cohort study used data from Taiwan's National Health Insurance Research Database between January 2011 and December 2020. Adults aged ≥50 years with a diagnosis of osteoporosis or fragility fractures were identified and compared with matched controls without these conditions. Propensity score matching was performed using age, sex, and Charlson Comorbidity Index. A second matched cohort compared patients treated with zoledronic acid or denosumab with untreated individuals. Incident hearing loss was the primary outcome. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazards models, with subgroup and sensitivity analyses conducted to assess sex differences and treatment duration effects.

Results

Individuals with osteoporosis or fragility fractures had a significantly higher risk of hearing loss compared with matched controls (adjusted HR 1.36, 95% CI 1.33–1.38). Among affected individuals, treatment with zoledronic acid (HR 0.87, 95% CI 0.81–0.93) or denosumab (HR 0.91, 95% CI 0.85–0.97) was associated with a significantly lower risk of hearing loss compared with no treatment. Subgroup analyses demonstrated that zoledronic acid was protective in both sexes, whereas the association for denosumab reached statistical significance only in males. Sensitivity analyses indicated that treatment durations of 2–4 years were associated with the greatest risk reduction.

Conclusion(s)

Osteoporosis and fragility fractures are associated with an increased risk of hearing loss. Long-acting injectable osteoporosis therapies, particularly zoledronic acid, are associated with a reduced risk of hearing loss, suggesting a potential extra-skeletal benefit beyond fracture prevention.

OP10 - P739

TRANSLATING MOLECULAR INSIGHTS INTO CLINICAL PROGRESS: RJX-01 FOR MUSCLE RECOVERY AND OSTEOSARCOPENIA THERAPY

A. Ugarte[1], S. Verheijden[1], L. Meuleners[1], E. Mercken[1], A. Beliën[1], J. Aerssens[1]

[1]Rejuvenate Biomed, Diepenbeek, Belgium

Objective

A phase 1b trial using an immobilization (casted leg) model showed that 6-week treatment with RJx-01 improved muscle strength and fatigue resistance. The molecular mechanisms behind RJx-01's effects remained largely unexplored and warrant further study. A phase 2 trial evaluating RJx-01 in hospitalization-associated sarcopenia among COPD patients is currently ongoing. Moving forward, we propose a second phase 2 trial targeting osteosarcopenia.

Material and Methods

In a phase 1 sub-study (placebo versus RJx-01-treated healthy males), transcriptomic profiling (RNA-seq) was performed on muscle biopsies from the immobilized leg at baseline, after 2 weeks immobilization, and after 4 weeks recovery.

Results

Transcriptomic analysis revealed significant changes post-immobilization in both groups: reduced expression of genes linked to mitochondrial energy metabolism and increased expression of genes related to inflammation, immune activation, and collagen fibrosis. After 4 weeks recovery, gene set enrichment analysis showed normalization of these disrupted pathways in the RJx-01 group but not in the placebo group. Complementary hematoxylin & eosin staining confirmed sustained inflammation in placebo subjects during recovery, which was reversed in RJx-01-treated subjects.

Osteosarcopenia is characterized by dynamic crosstalk between bone and muscle, mediated by a range of bioactive factors including myokines, osteokines, and adipokines. Recent studies indicate osteosarcopenia increases risk of disability, frailty, falls, fractures, hospitalization, and mortality compared to either condition alone (osteoporosis, sarcopenia). While pharmacological treatments exist for bone loss, there is an unmet need for sarcopenia therapies. Based on our phase 1 findings, we propose a placebo-controlled phase 2 study to evaluate whether a 6-months RJx-01 treatment can preserve muscle strength and function in postmenopausal osteosarcopenia patients. We hypothesize that RJx-01, combined with standard bone-loss therapy, may improve functional outcomes.

Conclusion

RJx-01 enhances muscle strength and recovery, supported by molecular and histological evidence. The proposed phase 2 trial will determine if RJx-01 can address the unmet need for sarcopenia treatment in osteosarcopenia patients, aiming to improve clinical outcomes and reduce disability.

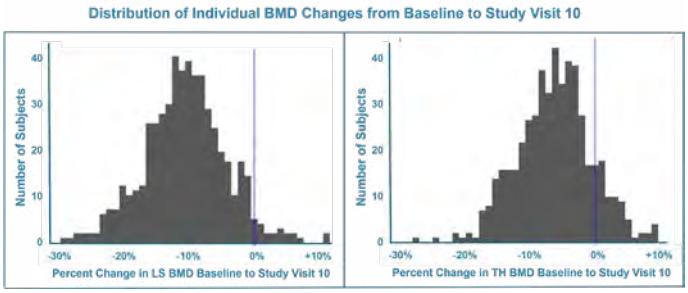
OP11 - P1094

WHAT PROPORTION OF WOMEN EXPERIENCE SIGNIFICANT TRANSMENOPAUSAL BONE LOSS?

M. McClung[1], A. Clark[2]

[1]Oregon Osteoporosis Center, Portland, OR, United States;
[2]Oregon Health & Science University, Portland, OR, United States

The relatively rapid bone loss that occurs during the menopausal transition is an important determinant of the subsequent development of postmenopausal osteoporosis. The Study of Women Across the Nation (SWAN) followed more than 3000 women across the menopausal transition. Reports from SWAN have described the average changes in bone mineral density (BMD) with average losses from 5 years before the final menstrual period (FMP) until 5 years after FMP of 10.6% in the lumbar spine and 9.1% at the femoral neck. Knowing the proportion and characteristics of women who experience significant bone loss during the menopausal transition would aid the development of appropriate strategies to prevent that bone loss in women at high risk for developing osteoporosis.



Objective: To evaluate the distributions of lumbar spine and total hip BMD changes in individual women in SWAN from baseline to Visit 10.

Design: A secondary analysis was conducted using the publicly available SWAN dataset, from baseline through 10 years of annual assessments. The analysis was limited to women undergoing natural menopause without exposure to bone-active drugs (estrogens, osteoporosis medications, tamoxifen, and chemotherapy).

All subjects who had BMD results at baseline and 10 years were evaluated. Menopause status at each visit was categorized as pre-, early peri-, late peri- or post menopause. Percentage change in lumbar spine (LS) and total hip (TH) BMD from baseline to 10 years was calculated. Analyses were conducted in RStudio, version 2024.12.1.

Results: 516 women met inclusion criteria. Mean age was 46.2 years; mean years of menopause 4.5; mean BMI 27.6. Average BMD values at baseline corresponded to T-scores of 0.18 at LS and 0.08 at TH. The average % changes in BMD were 10.4% at LS (almost 1 T-score) and 6.1% at TH. Distributions of individual changes in LS BMD are shown in the Figure. 88% and 72% of

women had losses of at least 3% at LS and TH, respectively, while 83% and 57% had losses of 5% or greater. Maximum individual losses exceeded 25% at both the spine and hip.

Conclusion: Almost all women experience significant bone loss during the menopausal transition, and many would benefit from therapy to prevent bone loss and osteoporosis.

Disclosures: None

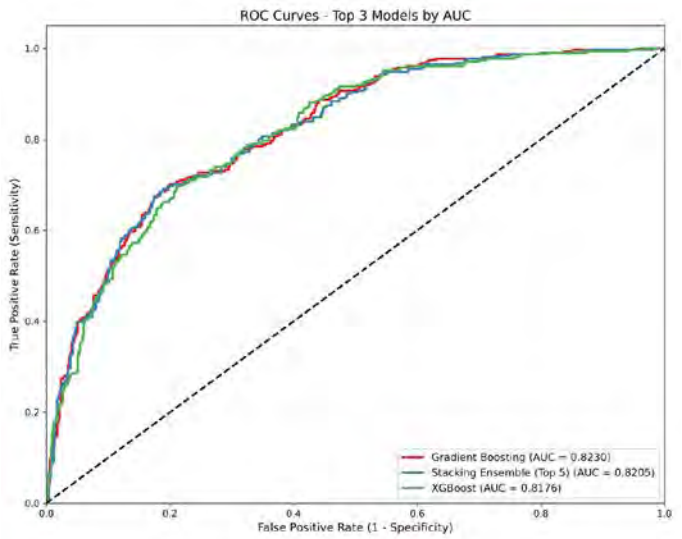
Objective: To design and evaluate machine learning approaches for osteoporosis screening.

Material and Methods: Using baseline data from the Bushehr Elderly Health (BEH) program, we developed screening tools defining osteoporosis as bone mineral density T-score ≤ -2.5 (lumbar spine, femoral neck, or total hip) by dual-energy X-ray absorptiometry. Data were partitioned into training (80%) and independent test (20%) sets. Fifteen algorithms were trained using hybrid feature selection (recursive elimination with logistic regression and XGBoost). We addressed class imbalance via SMOTEENN resampling within stratified cross-validation. Decision thresholds were constrained to maximize F2-score. Model performance was evaluated on the test set using AUC, sensitivity, specificity, and F2-score.

Results: Among 4,110 participants (median age: 66 years; 54.2% female; 37.8% osteoporosis prevalence), key predictors included weight, height, age, parity, and fracture cause. The voting ensemble achieved the highest screening performance (AUC 0.82, sensitivity 95.2%, specificity 39.3%, F2-score 0.80). Gradient boosting demonstrated balanced discrimination (AUC 0.82, sensitivity 90.7%, specificity 52.1%, F2-score 0.80), while LightGBM offered higher specificity (AUC 0.82, sensitivity 82.6%, specificity 60.7%, F2-score 0.75) (Table & Figure).



Conclusion: Machine learning enables effective osteoporosis screening; the voting ensemble excels at exclusion, while Gradient boosting optimizes discriminative balance. This allows tool selection based on surveillance goals and resource constraints. An online risk calculator was developed.

https://osteosarcopenia-risk-calculator-u9pvs4ecg7euxryfcec3mc.streamlit.app/

Table: Performance of the top five models for osteoporosis screening using 10 features.

Model	F2-Score	Sensitivity	Specificity	ROC-AUC
Voting Ensemble	0.800	0.952	0.393	0.817
Extra Trees	0.799	0.949	0.398	0.808
Gradient Boosting	0.796	0.907	0.521	0.823
AdaBoost	0.795	0.929	0.443	0.808
Random Forest	0.794	0.913	0.492	0.817
Feature importance: weight, height, age, parity, fracture cause, diabetes, difficulty walking, hormone replacement therapy, smoking status, difficulty climbing stairs.

OP13 - P1702

HOW COMMON IS IT? HIGH AND VERY HIGH-RISK FRACTURE RATES AMONG PATIENTS WITH A NON-OSTEOPOROTIC-RANGE BONE MINERAL DENSITY IN A DXA DATABASE FROM A TERTIARY MEDICAL CENTER

Y. Eden-Friedman[1,2], I. Vered[1], N. Tripto[3], N. Minsky[1,2], Y. Levy-Shraga[2,4], P. Rotman-Pikielny[2,5], L. Tripto-Shkolnik[1,2]

[1]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel; [2]Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel; [3]Recah Institute of physics, Hebrew University of Jerusalem, Jerusalem, Israel; [4]Pediatric Endocrinology Unit, The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Ramat Gan, Israel; [5]Department of Endocrinology, Meir Medical Center, Kfar Saba, Israel

Objective: Fracture risk assessment has become a mainstay of osteoporosis management. Treatment paradigms for patients with a high or, especially, very high fracture risk based on FRAX assessment prioritize first-line anabolic treatment, even when bone mineral density (BMD) is in the non-osteoporotic (NOP) range. However, data regarding the prevalence of high or very high fracture risk among patients with NOP-range BMD are scarce.

Material and Methods: We utilized computerized BMD data from a tertiary medical center between 2024 and 2025. BMD was measured by the Lunar Prodigy Advance densitometer, and country-specific FRAX calculation ± Trabecular Bone Score (TBS) adjustment was performed by the Encore v18 software. Risk factors were reported by a self-administered questionnaire. Patients were classified as osteoporotic according to T-score ≤-2.5 at either the femoral neck, total hip, or at least two lumbar spine vertebrae. High/very high fracture risk was defined as ≥3/4.5% for hip, or ≥20/30% for major osteoporotic fractures (MOF), respectively. Statistical analysis was performed using Python.

Results: Five thousand and fifteen patients aged 40 years or older (40.3% males, age 66.8 ± 8.9 years) performed BMD test during the study period and were included. Overall, 1523 (30.4%) were classified as osteoporotic and 3492 (69.6%) with a NOP BMD. Among those with a NOP BMD, 1054 (30.2%) had high hip fracture risk, while 639 (18.3%) had very high risk. In contrast, regarding MOF, only 199 (5.7%) had high risk, and 52 (1.5%) had very high risk. TBS adjustment did not significantly change these proportions (high/very high hip fracture risk: 28.9%, p=0.248/17.2% p=0.247, high/very high MOF risk 4.7%, p=0.067;/1.0%, p=0.051).

Patients with BMD-defined osteoporosis, compared to patients in the NOP high-risk group, were younger (67.9 vs. 73.8 years, p<0.001), more likely to be female (82.6% vs. 55.6%, p<0.001), and to have lower BMI (25.5 vs. 27.1 kg/m², p<0.001). Among those with NOP-range BMD, the mean lumbar spine1-4/femoral neck/total hip T-score was 0.10±1.58/-1.24±0.86/-0.56±1.07, respectively.

Conclusions: The proportion of patients with high or very high fracture risk categories despite NOP BMD is substantial and driven primarily by hip fracture risk. These data can inform reimbursement policy decisions regarding first-line anabolic treatment.

SERUM PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS) AND BONE MINERAL DENSITY IN NORWEGIAN ADOLESCENTS: SEX-SPECIFIC ASSOCIATIONS AND MIXTURE EFFECTS

J. Wang[1], M. Averina[2], S. Huber[2], G. Grimnes[3], G. Fosse[2], ?. Bjørnerem[4], E. Evensen[5], R. Joakimsen[3], J. Johansson[6]

[1]UiT-The Arctic University of Norway, Tromsø, Norway; [2]Department of Laboratory Medicine, University Hospital of North Norway, Tromsø, Norway; [3]Tromsø Endocrine Research Group, Department of Clinical Medicine, UiT-The Arctic University of Norway, Tromsø, Norway; [4]Department of Obstetrics and Gynecology, University Hospital of North Norway, Tromsø, Norway; [5]Department of Health and Care Sciences, Faculty of Health Sciences, UiT-The Arctic University of Norway, Tromsø , Norway; [6]Department of Community Medicine, Faculty of Health Sciences, UiT-The Arctic University of Norway, Tromsø , Norway

Background: Adolescence is the critical period for the development of peak bone mass (PBM). Per- and polyfluoroalkyl substances (PFAS) are widespread endocrine disruptors that may disturb skeletal development, but evidence in Nordic adolescents is limited.

Objectives: To evaluate sex-specific associations between serum PFAS and areal bone mineral density (aBMD) Z-scores among Norwegian adolescents.

Methods: This cross-sectional study utilised data from Fit Futures 1 (2010–2011), a cohort of adolescents in Northern Norway. Eighteen serum PFAS were quantified, and aBMD Z-scores (femoral neck, total hip, total body) were calculated using dual-energy X-ray absorptiometry. We used multivariable linear regression and mixture analyses (quantile g-computation and Bayesian kernel machine regression) to estimate sex-specific associations.

Results: Among 889 participants (421 girls and 468 boys; mean age 16.2 years), eight PFAS had detection rates >70%. The sum of linear and branched perfluorooctane sulfonic acid (ΣPFOS) had the highest median concentration (6.23 ng/ml). Perfluorononanoic acid (PFNA) (β = −0.16 per doubling, 95% CI: −0.26, −0.06) and perfluorodecanoic acid (PFDA) (β = −0.15 per doubling, 95% CI: −0.24, −0.06) showed consistent inverse association with total body aBMD. Mixture analyses suggested modest overall adverse mixture effects, with limited evidence of interaction between PFAS. Sex-specific patterns showed more pronounced inverse associations in boys.

Conclusions: Higher concentrations of several PFAS, most consistently PFNA and PFDA, were associated with lower aBMD Z-scores, with stronger inverse patterns in boys. These findings suggest possible sex-specific vulnerabilities in bone accrual, underscoring the need for longitudinal studies to clarify long-term skeletal impacts.

MATERNAL DIABETES IN PREGNANCY AND FRACTURE RISK IN OFFSPRING: A VICTORIA STATE-WIDE DATA LINKAGE STUDY

P. N. C. Che[1], M. B. Breslin[1], M. T. Thompson[2], M. D. Dalton[1], F. J. Johnston[1], L. S. Lieke[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; [2]Department of Endocrinology, Royal Hobart Hospital, Hobart, Australia

Objective

Maternal diabetes in pregnancy may influence fetal skeletal development; therefore, this study examined the association between maternal diabetes subtype and hazard of first long-bone fracture in offspring during the first nine years of life.

Materials and Methods

We conducted a population-based cohort study using linked administrative health data for singleton births in Victoria, Australia. Maternal gestational diabetes (GDM), type 1 diabetes (T1DM), or type 2 diabetes (T2DM) status was identified from the Victorian Perinatal Data Collection (2012–2015) using ICD-10-AM codes. Offspring time to first long-bone fracture and censoring was ascertained from emergency department records between 2013 and 2021 and modelled using Cox proportional hazards regression, with maternal diabetes subtype as the exposure. Models were adjusted for offspring sex, index of relative socioeconomic disadvantage, and maternal smoking during pregnancy.

Results

Among 279,067 mother–offspring pairs, 22,153 (8.0%) mothers had GDM, 998 (0.4%) had T1DM, and 885 (0.3%) had T2DM. A total of 15,275 (5.7%) offspring sustained at least one incident long-bone fracture during follow-up. Compared with offspring of mothers without diabetes, fracture hazard ratio was lower among offspring exposed to GDM (hazard ratio [HR] 0.90; 95% confidence interval [CI] 0.84–0.96), higher among those exposed to T1DM (HR 1.28; 95% CI 1.00–1.64), and not significantly different for T2DM (HR 0.92; 95% CI 0.68–1.25).

Conclusion

Offspring fracture hazard differed by maternal diabetes subtype, with higher hazard following T1DM and lower hazard following GDM, the latter likely reflecting behavioural rather than skeletal factors. Early monitoring and targeted injury-prevention strategies may benefit offspring exposed to maternal T1DM.

SEX- AND DISTRIBUTION-SPECIFIC PROSPECTIVE MUSCLE-FAT-FRACTURE RELATIONSHIPS IN UK BIOBANK

E. M. Curtis[1], S. X. Lin[1], S. D'Angelo[1], L. Westbury[1], R. Moon[1], C. Cooper[1], K. A. Ward[1], N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objectives

We aimed to quantify the prospective associations between site-specific MRIderived fat and muscle volumes and incident fracture in the UK Biobank Imaging Study.

Materials and Methods

We analysed data from UK Biobank Imaging Study participants with MRIderived visceral adipose tissue volume (VAT), abdominal subcutaneous adipose tissue volume (ASAT) and thigh muscle volume (TMV) as exposures. The primary outcome was first osteoporotic fracture, ascertained via hospital record linkage. Cox proportional hazards models were used to estimate hazard ratios (HRs) per standard deviation (SD) increase in each exposure, adjusting for age, socioeconomic deprivation, smoking, exercise, diabetes, and prior fracture. Femoral neck bone mineral density (BMD) adjustments were applied in sensitivity analyses. Participants were followed until first osteoporotic fracture, death, loss to followup or 31 March 2023.

Results

The dataset comprised 50,151 participants (mean age: women 63.7 years; men 65.1 years) with MRI data. 806 incident osteoporotic fractures occurred during a total 223,069 person-years follow-

up time. In fully adjusted models, higher ASAT was consistently associated with lower fracture risk in both sexes [women HR/SD(95%CI): 0.67(0.60–0.74); men 0.79(0.67–0.93)], with similar findings for VAT [women 0.67(0.59-0.75); men 0.82(0.71-0.95)]. These associations remained robust after adjustment for BMD, except for VAT in men. Greater TMV was associated with lower fracture risk in women [0.74(0.64-0.86)] but this relationship was substantially attenuated by adjustment for BMD [0.92(0.78-1.08)], and there was no evidence of an association in men [1.03(0.83-1.28)].

Conclusions

Greater fat volume in subcutaneous or visceral compartments was protective against incident osteoporotic fracture in both sexes, as was greater thigh muscle volume in women, but not men. Associations between incident fracture and visceral adipose tissue (men) or thigh muscle (women) volume appeared BMD-dependent. These findings inform fracture risk assessment and biological understanding of body composition in skeletal health. (UK Biobank access application 3593).

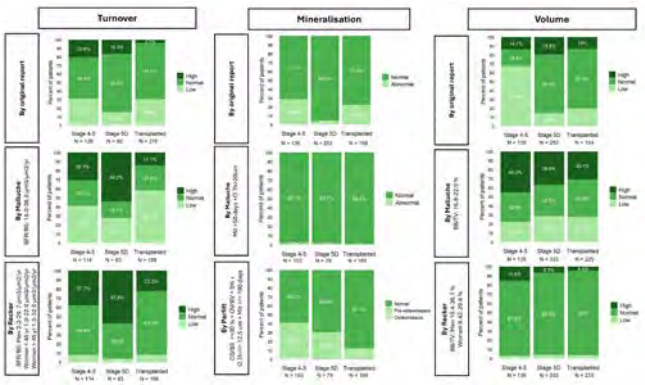
THE LANDSCAPE OF RENAL OSTEODYSTROPHY IN EUROPE: A FIRST REPORT FROM THE EUROD BONE BIOPSY DATABASE

I. Ystrøm[1], S. Salam[2], G. Spasovski[3], A. Ferreira[4], A. C. Ferreira[4], S. Keronen[5], H. Kröger[6], P. Evenepoel[7], H. S. Jørgensen[1]



[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [2]Division of Clinical Medicine, University of Sheffield, Sheffield, United Kingdom; [3]Methodius, Skopje, North Macedonia; [4]Nova Medical School, Lisbon, Portugal; [5]Department of Nephrology, Helsinki University Hospital, Helsinki, Finland; [6]Kuopio Musculoskeletal Research Unit, University of Eastern Finland, Kuopio, Finland; [7]Department of Medicine, Division of Nephrology, UZ Leuven, Leuven, Belgium

Objective: Renal osteodystrophy (ROD) is a major complication of chronic kidney disease (CKD), yet its epidemiology is poorly defined due to the declining use of bone biopsy both in clinical practice and research. Earlier studies indicated a shift from high to low turnover bone disease in CKD[1], but the current spectrum of ROD is uncertain. This study reports from a multicenter bone biopsy database to address this knowledge gap.

Methods: Bone biopsies from 5 countries, collected between 1998 and 2025 were included. Biopsies were from patients across the spectrum of kidney dysfunction, including pre-dialysis, on dialysis, and after kidney transplantation. All centers reported the TMV classification for bone turnover (low, normal, high), mineralisation (normal, abnormal), and volume (low, normal, high). In addition, re-classification to common diagnostic definitions were performed using previously published cut-offs[2].

Results: A total of 851 bone biopsies were available. Of these, 155 were excluded (duplicates, incomplete registrations, or performed on clinical indication). The remaining 696 research-indication biopsies were stratified on CKD grade: Predialysis (CKDG4-5; n=135), on dialysis (CKDG5D, n=335), and post-transplant (TX, n=225). Median age at time of biopsy was 57 years, 32% were female, and 19% had diabetes mellitus. Antiosteoporosis medication was rarely used (CKDG4; 0%, CKDG5D: 2%, TX: 6%). TMV-classification showed high variation depending on cutoffs applied (**Fig** 1). By the original report, normal bone turnover was the most common presentation for all patients. For tetracycline-labeled biopsies (N=341) additional diagnostic definitions were applied. By the Malluche definition[1], the majority of patients in CKDG4-5 and CKDG5D had high bone turnover. This was also the case with the Recker definition[3,4], which labeled all patients as either high or normal bone turnover. Bone mineralization defects were reported for a notable proportion of patients in CKDG4-5, as well as TX

Conclusion: The presentation of ROD was mainly normal to high bone turnover in bone biopsies performed in research context over the past two decades in Europe. Contrary to previous reports, low bone turnover was not dominant. Classification was highly variable depending on diagnostic cutoffs applied, and further efforts should be directed at harmonizing diagnostic criteria. The presence of abnormal bone mineralisation in a sizeable number of patients deserves further attention.

LONG-TERM QUALITY OF LIFE TRAJECTORIES IN FIBROUS DYSPLASIA AND MCCUNE-ALBRIGHT SYNDROME

R. Vijjhalwar[1], F. Clemeno[1], M. A. Legrand[1], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objectives: Fibrous dysplasia and McCune-Albright syndrome (FD/MAS) are associated with substantial morbidity, yet long-term patient-reported outcomes remain poorly characterised. We describe longitudinal health-related quality of life (HRQoL) trajectories in FD/MAS and identify clinically meaningful subgroups at differential risk of deterioration using generic HRQoL (EQ-5D) data.

Material and Methods: We analysed longitudinal EQ-5D-5L data from 74 adults with participant-reported FD/MAS contributing 509 HRQoL observations (median follow-up 6.5 years) from the UK-based RUDY research database (www.rudystudy.org). Linear mixed-effects models estimated annual changes across EQ-5D domains and VAS, adjusting for age, sex, and year of entry. EQ-5D index scores were derived using validated algorithms. Patients with ≥2 measurements underwent unsupervised clustering of baseline-to-follow-up EQ-5D index change. K-means clustering (k=2) was compared with Gaussian mixture modelling (GMM). Baseline associations with cluster membership were tested using Fisher's exact tests.

Results: Population-level analyses showed overall significant annual worsening in mobility, self-care, and anxiety/depression, with declining EQ-5D VAS scores, while pain/discomfort and usual activities remained stable. Clustering identified two distinct trajectories. A high-risk "decliner" group (≈30%) had poor baseline HRQoL (mean EQ-5D index 0.33) with marked deterioration over time (mean change -0.23), while a second majority group remained stable or slightly improved (Figure 1). Baseline EQ-5D index <0.5 was strongly associated with high-risk cluster membership (p=0.0005), whereas age and sex showed no association.

Conclusions: FD/MAS patients demonstrate heterogeneous long-term HRQoL trajectories. A substantial subgroup experiences a severe, progressive decline that may be identified at first assessment using baseline EQ-5D index scores. Early recognition may support targeted monitoring, multidisciplinary intervention, and future trials in this rare disease population.

Declarations: RV, FC, MAL, RPV nothing to declare. MKJ received paid consultancy or sponsorship for external talks from Amgen, UCB, Sanofi, Kyowa Kirin, Nanox-AI, Native Technologies, Thornton Ross and Theramex

IMPAIRED ORAL HEALTH PREDICTS FRACTURES AND FALLS IN OLDER ADULTS: A PROSPECTIVE COHORT STUDY

A. Kada[1], N. Chebib[2], M. Papageorgiou[1], M. Hars[1], A. Trombetti[1], S. Ferrari[1], F. Müller[2], E. Biver[1]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland; [2]Division of Gerodontology and Removable Prosthodontics, University Clinics of Dental Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland

Objective

The interplay between age-related declines in oral and musculoskeletal health, nutrition, and lifestyle in older adults remains poorly understood. The associations between oral health, fractures, falls, and lifestyle factors were investigated in a prospective cohort of older adults.

Methods

A total of 747 participants from the Geneva Retirees Cohort (mean age 67.9 ± 1.5 years; 80% women) were included with a mean follow up of 5.5 ± 1.8 years. Subjective oral health was assessed using the Geriatric Oral Health Assessment Index (GOHAI), a self-reported questionnaire covering functional, psychosocial, and pain/discomfort dimensions. In addition, number of teeth, presence of dental prostheses and/or implants and xerostomia were documented. Incident low-trauma fractures and non-traumatic falls were recorded. Bone density and body composition were assessed by DXA, bone microarchitecture and estimated bone strength by HR-pQCT with finite element analyses, and dietary intake using a food frequency questionnaire. All analyses were adjusted for age and sex.

Results

A total of 85 incident fractures and 230 individuals with at least one fall were recorded. Oral pain/discomfort and oral function impairment were associated with a higher risk of incident fractures (HR 95% CI per one-point decrease in GOHAI score, 1.18 (1.03, 1.35) and 1.09 (1.01, 1.18), respectively). The association of oral pain/discomfort was independent of hip BMD and FRAX. Teeth loss (<24 remaining teeth) and xerostomia were associated with an increased risk of falls (HR 1.53 (1.08, 2.16) and 1.69 (1.06, 2.7), respectively). Participants with teeth loss had lower trabecular density and reduced bone strength at the tibia. Participants with oral functional impairment and/or teeth loss had lower calcium and/or protein intakes, a higher BMI, lower physical activity levels, and a higher prevalence of smoking, without differences in muscle parameters.

Conclusion

Oral health may reflect musculoskeletal fragility beyond bone density measures and FRAX. Perceived pain and functional limitations were associated with an increased risk of fractures, while teeth loss and xerostomia were associated with falls. These associations appear partly related to nutrition and lifestyle

factors, suggesting that maintaining a healthy lifestyle could improve both oral and musculoskeletal health. Supporting oral health in older adults may also contribute to support nutrition and a better musculoskeletal health.

THE SINTER STUDY: A RECALL-BY-GENOTYPE DESIGN WITH MULTIDIMENSIONAL MUSCULOSKELETAL PHENOTYPING ACROSS INTERNAL-MEDICINE OUTPATIENT CLINICS

F. Koromani*[1], K. Huininga*[1], S. Li[1], K. Trajanoska[1], K. Berk[1], M. Boon[1], L. Chaker[1], P. van Daele[1], J. Hofland[1], M. van Hoek[1], M. Hemmelder[1], J. Roeters van Lennep[1], M. Medici[1], J. Olieman[1], B. Ozcan[1], R. Peters[1], F. Mattace-Raso[1], E. Mulugeta[1], E. F. C. van Rossum[1], J. van Rooij[1], A. Uitterlinden[1], W. Visser[1], E. F. van Velsen[1], M. C. Zillikens[1], F. Rivadeneira[1]

[1]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands

Objectives

We describe the design of the EraSmus medIcal CeNTer skEletal fRagility (SINTER) Study, an observational clinical study integrating polygenic risk stratification with advanced musculoskeletal imaging and functional phenotyping to improve characterisation of skeletal fragility in chronic conditions.

Methods and Materials

SINTER is conducted across nine internal medicine outpatient clinics in two stages. First, 5,650 patients undergo genotyping. Second, ~1,500 individuals from the extremes of the polygenic score for bone mineral density (PGSBMD), plus 400 patients with mastocytosis are recalled for musculoskeletal phenotyping. Imaging includes DXA, EOS Edge imaging for three-dimensional spinal alignment and global biomechanics, and peripheral quantitative computed tomography for volumetric density and microarchitectural assessment. Skeletal material and tissue-level properties are assessed using quantitative ultrasound and reference point indentation. Muscle function and physical performance are evaluated using mechanography and handgrip strength. Lifestyle data are extracted from questionnaires, alongside patient-reported outcomes and perceptions related to musculoskeletal health. To validate the RbG design, simulation analyses were performed in the population-based Rotterdam Study, comparing clinical and skeletal characteristics between individuals selected from low and high extremes of the PGSBMD distribution.

Results

Ethical approval has been obtained, and recruitment is ongoing. In the Rotterdam Study, selection based on PGSBMD extremes, results in the expected separation in femoral neck BMD and osteoporotic fracture prevalence, while clinical and lifestyle characteristics remain well balanced, supporting the randomisation properties of the RbG approach (Table).

Conclusions

SINTER establishes a clinically embedded research framework that integrates genetic information with advanced musculoskeletal imaging and functional assessment. Validation in an independent population-based cohort demonstrates that RbG stratification based on polygenic scores achieves randomisation-like balance of clinical characteristics while enriching for skeletal fragility phenotypes, supporting its use for mechanistic musculoskeletal research.

Table. Characteristics of the study population compared between low and high BMD wPGS.

DEVELOPMENT AND EXPERT VALIDATION OF AN INTERNATIONAL POSTMENOPAUSAL OSTEOPOROSIS RISK ASSESSMENT AND LIFESTYLE (IPORL) QUESTIONNAIRE

F. Alradini[1], A. Alblooshi[2]

[1]Department of Family and Community Medicine, College of Medicine, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia; [2]Department of Medical Education, College of medicine and health Sciences, United Arab Emirates (UAE) University, Al Ain, Abu Dhabi, United Arab Emirates

Background: Osteoporosis affects over 200 million women globally, contributing to significant morbidity and socioeconomic burden. Despite the availability of standardized tools such as FRAX and OKAT, few instruments comprehensively assess both biomedical and lifestyle risk factors while remaining adaptable for Postmenopausal women internationally.

Objective: To develop and establish the content validity of an internationally adaptable osteoporosis risk and lifestyle questionnaire for postmenopausal women.

Methods: A 60-item questionnaire was constructed from four validated frameworks: The Menopause Rating Scale (MRS), The Osteoporosis Knowledge Assessment Tool (OKAT), WHO FRAX clinical risk factors, and WHO STEPwise (STEPS) approach. Sociodemographic data were incorporated as the first section of the instrument. Twenty-two multidisciplinary experts in endocrinology, gynecology, family medicine, orthopedics, and public health independently rated each item for relevance, clarity, and necessity on a 4-point scale. The Item-level Content Validity Index (I-CVI) for relevance and modified kappa (k*) were calculated as well as comment burden for each item. Qualitative feedback underwent further content analysis. Decisions to retain, revise, or remove items were based on integrated quantitative and qualitative analysis of experts' recommendations.

Results: Quantitative analysis showed relevance I-CVI values ranging from 0.68–1.00 (S-CVI = 0.92); k* values 0.67–1.00, indicating good to excellent agreement. Comment burdens per item were predominantly low, with 36 items (60%) receiving 0–2 comments, 17 items (28%) receiving 3–5 comments, and only 7 items (12%) receiving six or more comments. Therefore, 32 items retained, 27 revised, and 1 removed. Following further qualitative analysis of the experts' comments, 26 were retained, 32 revised, and 2 removed (household income and menstrual irregularity). Overall, 98% of expert-endorsed items were retained or refined, yielding a 58-item final version.

Conclusion: The International Postmenopausal Osteoporosis Risk assessment and Lifestyle Questionnaire (IPORL-Q) comprising 58 items across five sections 1) Sociodemographic, 2) The Menopause Rating Scale (MRS), 3) Osteoporosis Knowledge Assessment Tool (OKAT), 4) WHO FRAX clinical risk factors, and 5) The WHO STEPwise (STEPS) approach. The IPORL-Q demonstrates excellent content validity, linguistic clarity, and adaptability for global use. It provides a robust foundation for psychometric validation and cross-cultural research in postmenopausal osteoporosis assessment and prevention.

FRACTURES AND BONE MINERAL DENSITY LOSS IN ADULTS LIVING WITH HIV IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. L. Gregson[1], M. Westby[2], A. De Wilton[1], T. Madanhire[3], J. Savovic[2], G. Gwaze[4], M. Vitoria[5], J. Amuthavalli Thiyagarajan[5], K. A. Ward[6]

[1]Global Health and Ageing Research Unit, University of Bristol, Bristol, United Kingdom; [2]Population Health Sciences, University of Bristol, Bristol, United Kingdom; [3]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom; [4]The Health Research Unit, Biomedical Research and Training Institute, Harare, Zimbabwe; [5]The World Health Organization, Geneva, Switzerland; [6]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective

To synthesise low- and middle-income country (LMIC) evidence on fractures and bone mineral density (BMD) loss, including associations with antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) and fracture/BMD risk factors, in adult people living with HIV (PLHIV) or using PrEP.

Methods

We searched Embase, Medline, SciElo, WHO Global Index Medicus for evidence on fractures and BMD in PLHIV in LMICs. Analysis included meta-analysis, network meta-analysis (NMA) and component NMA. We examined heterogeneity with subgroup analysis and meta-regression. 38 studies were included. PROSPERO: CRD42024587101

Results

Pooled fracture prevalence was 10% [95%CI 5, 16%] (self-reported/vertebral imaging) (n=20 studies), 19% [11, 30%] in PLHIV for >5 years, and 25% [14, 39%] with vertebral imaging. HIV is associated with prevalent fracture OR 2.1 [1.2, 3.6] (n=2 studies). In longitudinal DXA studies PLHIV have greater BMD loss than HIV-negative adults, varying with type of ART: over 1-year TDF-ART is associated with 3.5% [3.0, 4.1] more BMD loss (4 studies; n=577) than HIV negative groups. In PLHIV, fracture risk factor analyses for traditional risk factors were sparse and imprecise (few fractures). Lower BMI and smoking were most consistently associated with future BMD loss. TDF ART vs non-TDF ART may be associated with prevalent fracture (pooled OR 1.7, [0.72, 4.1]). For PrEP, NMA of 7 RCTs (21,236 people) suggests TDF monotherapy vs placebo may increase fracture risk (RR 1.3 [0.97, 1.7], but GRADE low certainty evidence). However, TDF PrEP (vs placebo) is associated with greater BMD loss, more so in those adhering to PrEP (BMD difference −1.2% [−1.6, −0.81]). In PLHIV, RCT evidence shows lower BMD for TDF vs non-TDF ART. No study investigated fracture prevention. Two small pilot studies showed

possible benefits of exercise on BMD. Two studies concluded FRAX assessment may underestimate fracture risk in PLHIV.

Conclusion

Fractures are frequent in adult PLHIV in LMICs. Exposure to TDF and smoking accelerate bone loss and may increase fracture risk, with TDF-related BMD declines like those seen in menopause. Other risk factors are understudied, and research mainly involves adults <50yrs. Existing risk assessment tools may underestimate fracture risk in adult PLHIV, and significant evidence gaps remain.

[1]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [3]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; [4]College of Medicine and Public Health, Flinders University, Adelaide, Australia; [5]Department of Medicine, University of Manitoba, Manitoba, Canada; [6]xxx, Sheffield, United Kingdom

Introduction: This study aimed to quantify the relationship between DXA-measured femoral neck bone mineral density (BMD) and future fracture risk, and to assess the modifying effects of age, sex and time since measurement on fracture risk, with a view to updating FRAX®.

Methods: We analysed data from 307,205 men and women across 53 predominately population-based cohorts with an average follow up of 8.7 years and a total of 2,683,185 person-years. The association between BMD and fracture risk was examined using an extended Poisson model in each cohort separately by sex. Results were expressed as a gradient of risk (GR), defined as the hazard ratio per standard deviation decrease in BMD t score for the outcome fracture. Cohort-specific results were then merged using weighted coefficients.

Results: Femoral neck BMD strongly predicted hip fractures both in men (GR 2.31, 95% CI 2.18-2.46) and women (GR 2.03, 95% CI 1.91-2.16) (Figure). However, the magnitude of association was significantly dependent on age, with a higher gradient of risk at younger ages. For example, at age 50 years, the GR was 3.49 (95% CI: 2.51, 4.84) in men and decreased to 2.14 (95% CI: 1.96, 2.34) at age 80 years. The decline in GR with age was similar in women: 3.23 (95% CI: 2.75, 3.80) and 2.11 (95% CI: 1.99, 2.44), respectively. The GR for major osteoporotic fracture (MOF) remained unchanged with age (p=0.89 for men and p=0.12 for women). A significant decrease in GR for hip fracture was observed with increasing duration of follow up but the magnitude of the effect was modest relative to the effect of age. For other fracture outcomes, including non-hip major osteoporotic fracture, the gradient of risk was lower than for hip fracture.

Conclusions: Femoral neck BMD is an important risk factor for future hip fracture. The slightly lower magnitude of association at older age is consistent with other, non-skeletal factors contributing to hip fracture risk. This international validation supports the use of BMD in case finding strategies. Its use should, however, take account of the variations in predictive value with age, sex and length of follow up.

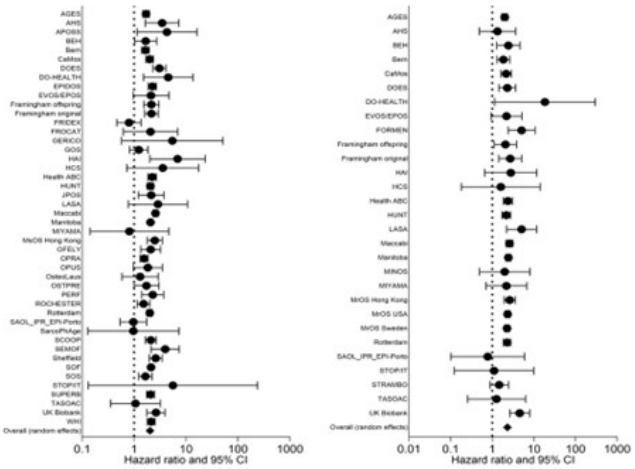

Fig 1 Forest plots of the association between BMD and risk of a subsequent hip fracture for women (left) and for men (right). Effect estimates (hazard ratios/SD) are shown for fracture (circles), adjusted for age, sex and duration of follow-up. The horizontal lines represent 95% confidence intervals.

Objective(s)

We assessed whether first DXA scans are performed too late in life to allow for a five-year treatment benefit period.

Material and methods

We identified first routine-care DXA scans (2010–2022) from the NOCTE cohort[1] and matched patients on sex, age, region from the background population. We estimated Mortality Rates (MR), Standardized Mortality Ratios (SMR), as well as 5- and 10-year survival.

Results

We included 72,818 men and 172,622 women with first DXA scans and their matched controls. Median follow-up was 5.5 years (men) and 7.0 years (women). Post-DXA 5-year survival was 73% in men vs. 87% in women (Table 1), with a significantly higher male (+56%) than female (+17%) SMR increase relative to background.

Table 1. Mortality rates and Survival

Group	N	Age at index (Mean, sd)	T-score < -2.5 at index (%)	MOF[a] 1 yr prior index (%)	MR Per 1000 PY (95% CI)	SMR (95% CI)	Survival 5y / 10y
MEN							
Background	386,075	71.8 (8.4)	Unknown	0.6%	41.4 (40.8 ; 41.3)	Ref.	83% / 65%
DXA	72,818	71.8 (8.4)	16.5%	9.7%	64.4 (63.6 ; 65.2)	1.56 (1.53 ; 1.59)	73% / 52%
WOMEN							
Background	932,176	70.3 (9.1)	Unknown	1.4%	28.5 (28.3 ; 28.6)	Ref.	88% / 75%
DXA	172,622	70.3 (9.1)	33.4%	12.4%	33.2 (32.9 ; 33.5)	1.17 (1.16 ; 1.18)	87% / 71%

[a]*MOF: Major Osteoporotic Fracture*

Conclusion

Men have higher excess mortality as reflected in the difference in SMR by sex and worse 5 and 10-year survival, with 73% surviving 5 years and only 52% surviving 10 years post-DXA, compared to 87% and 71% of women. This is despite women presenting more often with T-scores under –2.5 and/or a recent MOF. The amplified discrepancy in survival suggests that current referral patterns still lack sufficient focus on male osteoporosis, hindering opportunities for timely and effective treatment intervention.

EARLY INITIATION OF OSTEOPOROSIS TREATMENT AFTER FRACTURE REDUCES SECONDARY FRACTURES IN ADULTS AGED ≥75 YEARS

M. Tsukamoto[1], T. Hamasaki[2], N. Okimoto[3], Y. Saito[4], S. Fujiwara[5]

[1]Department of Orthopaedic Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan; [2]Department of Orthopaedic Surgery, Chugoku Rosai Hospital, Kure, Japan; [3]Okimoto Clinic, Kure, Japan; [4]Datack Inc., Tokyo, Japan; [5]Yasuda Women's University, Hiroshima, Japan

Objective

To evaluate whether initiation of osteoporosis medication within 3 months after fracture and continuation for at least 6 months reduces secondary fracture risk in adults aged ≥75 years.

Material and Methods

This study emulated a randomized target trial using Japanese administrative claims data from the DeSC database (2014–2022). Individuals aged ≥75 years with a recent osteoporotic fracture were classified as exposed if osteoporosis medication was initiated within 90 days after fracture, or as controls otherwise. High-dimensional propensity score matching was applied to balance baseline characteristics. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for any secondary fracture and site-specific fractures. Treatment effects were evaluated according to treatment duration: initiation regardless of duration, continuation for ≥6 months, and continuation for ≥12 months.

Results

Among 203,534 eligible individuals, 53,436 matched participants (mean age 83.7 years; 77.9% women) were included. Initiation and continuation of osteoporosis medication significantly reduced the risk of any secondary fracture, with HRs of 0.78 (95% CI 0.70–0.84) after ≥6 months and 0.74 (95% CI 0.65–0.83) after ≥12 months of treatment. Hip fracture risk was markedly reduced after ≥6 months in both men (HR 0.56, 95% CI 0.36–0.80) and women (HR 0.60, 95% CI 0.49–0.72). The magnitude of fracture risk reduction was comparable between sexes.

Conclusion

Early initiation and sustained use of osteoporosis medication after fracture substantially reduce the risk of secondary fractures, particularly hip fractures, in adults aged ≥75 years. These findings support prompt pharmacological intervention for secondary fracture prevention in older adults of both sexes.

OC4

TIMING OF ANTI-OSTEOPOROTIC TREATMENT INITIATION AFTER VERTEBRAL FRACTURE AND RISK OF NEW FRACTURE IN A FLS MODEL

P. Perez Andrés[1], C. Reyes Diez[1], M. J. Montesa Cabrera[1], B. Gonzalez Alvarez[1], N. Padron Orozco[1]

[1]Department of Rheumatology, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: Vertebral fractures are the most common osteoporotic fractures and represent a critical window for secondary fracture prevention. Although early initiation of anti-osteoporotic treatment is recommended, timing in real-world practice remains unclear. Objective: To assess the association between the timing of anti-osteoporotic treatment initiation after a vertebral fracture and the risk of subsequent vertebral fractures. Material and Methods: We conducted a retrospective, single-center observational study that included patients aged ≥50 with a recent fragility vertebral fracture who were followed in a Fracture Liaison Service (FLS) between 2017 and 2023. Treatment initiation was categorized as ≤90, 91–180, or 181–365 days after the index fracture. The primary outcome was incident vertebral fracture. A Cox proportional hazards model with time-dependent exposure was used, adjusting for relevant clinical covariates. Results: A total of 260 patients with a follow-up longer than one year were analyzed. Treatment was initiated within ≤90 days in 27.3% of patients, between 91–180 days in 39.6%, and between 181–365 days in 33.1%. The incidence of new vertebral fractures was 14.1%, 14.6%, and 9.3%, respectively. In the adjusted Cox model, treatment initiation between 91-180 days was associated with a higher hazard of new vertebral fracture compared with the unexposed period (HR 10.62; 95% CI 1.16–97.55; p=0.037), whereas the other groups did not show statistically significant associations.These findings should be interpreted with caution due to confounding by indication and low event rates. Conclusions: The incidence of new vertebral fractures was similar among patients who initiated treatment within the first six months after the index fracture and lower among those with later treatment initiation. The low incidence of new fractures may be related to the early detection in FLS programs, underscoring their importance in secondary fracture prevention.

THE NUMBER NEEDED TO TREAT (NNT) ANALYSIS: A CLINICAL CONTEXT FOR THE TREATMENT-RELATED CHANGE IN TOTAL HIP BONE MINERAL DENSITY: THE ASBMR-SABRE PROJECT

T. Vilaca[1], L. Lui[2], M. Schini[1], S. K. Ewing[3], A. Thompson[3], E. Vittinghoff[3], D. C. Bauer[3], B. Langdahl[4], D. Black[3], M. Bouxsein[5], R. Eastell[1]

[1]University of Sheffield, Sheffield, United Kingdom; [2]California Pacific Medical Center, San Francisco, United States; [3]University of California, San Francisco, United States; [4]Aarhus University, Aarhust, Denmark; [5]Harvard Medical School, Boston, United States

Objective: The Study to Advance Bone Mineral Density as a Regulatory Endpoint (SABRE) has demonstrated that the treatment-related difference (active–placebo) in total hip bone mineral density percent change at 24 months (Δ%THBMD) is an excellent surrogate for fracture risk reduction. In this analysis, we estimated the clinical significance of Δ%THBMD by calculating the number needed to treat (NNT) to prevent one fracture over a three-year period, providing a direct measure of treatment benefit.

Methods: NNTs were derived from absolute risk reduction, defined as the difference in fracture incidence between treated and placebo groups. We calculated NNTs for vertebral and hip fractures for Δ%THBMD changes of 3% and 5%. Because NNT depends on background fracture incidence, we estimated 3-year fracture rates for each fracture type among placebo participants. We evaluated NNTs across the lowest, first quartile, median, third quartile, and highest incidence categories. Meta-regression curves were used to estimate relative risk as a function of Δ%THBMD change across these incidence levels.

Results: We analysed data from 25 randomised, placebo-controlled trials, comprising 137,717 participants receiving bisphosphonates (n=13 trials), odanacatib (n=1), hormone therapy (n=2), parathyroid hormone receptor agonists (n=3), denosumab (n=1), selective oestrogen receptor modulators (n=4), and romosozumab (n=1).

NNTs decreased with higher fracture incidence and greater Δ%THBMD change. For a 3% increase in Δ%THBMD, NNTs for vertebral fractures ranged from 79 (2.8% incidence) to 7 (30.2% incidence) (panel A) and for hip fractures, from 1,408 (0.3% incidence) to 88 (4.8% incidence). At 5% Δ%THBMD, NNTs for vertebral fractures ranged from 56 to 5 and for hip, 757 to 47 respectively (panel B).

Conclusion: Integrating fracture risk reduction with NNT estimates based on treatment-related total hip BMD changes provides a clinically meaningful framework for quantifying treatment benefit in osteoporosis. This approach supports patient-centred interpretation of trial outcomes and may inform future trial design and regulatory evaluation.

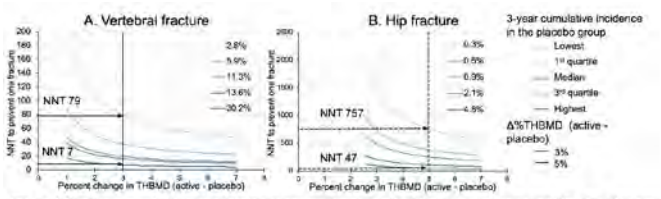

Figure A Numbers-needed-to-treat (NNT) to prevent one vertebral fracture at lowest and highest fracture incidence observed in placebo groups at 3% difference (active - placebo) in 24-month mean increase in total hip bone mineral density (Δ%THBMD). ADHERENCE TO CARDIOVASCULAR RISK MINIMIZATION MEASURES FOR ROMOSOZUMAB: INTERIM RESULTS FROM A EUROPEAN MULTI-DATABASE DRUG UTILISATION STUDY

E. H. Tan[1], T. Rathod-Mistry[1], M. T. Sanchez-Santos[1], C. Reyes[2,3], M. Far[3], J. Reinold[4], L. Pederson[5], B. Darvalics[5], K. Verhamme[6], A. Brutau Abia[7], F. Riefolo[7], P. Beukelaers[8], S. Lisart[8], A. Moayerri[9], D. Prieto-Alhambra[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]EAP Sardenya-Research Institute Sant Pau (EAP Sardenya-IR Sant Pau), Sardenya Primary Health Care Center, Barcelona, Spain; [3]Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain; [4]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Department of Clinical Epidemiology, Bremen, Germany; [5]Aarhus University Hospital and Aarhus University, Department of Clinical Epidemiology, Aarhus, Denmark; [6]Erasmus MC, Department of Medical Informatics, Rotterdam, Netherlands; [7]Teamit Institute, Partnerships, Barcelona, Spain; [8]UCB, Brussels, Belgium; [9]UCB, Slough, United Kingdom

Objective(s): Romosozumab (Romo) is approved for the treatment of severe osteoporosis (OP) in postmenopausal women at high fracture risk but contraindicated in those with prior myocardial infarction (MI) or stroke in Europe. Monitoring of real-world adherence to the risk minimization measures (RMMs) is essential for patient safety. We aim to describe compliance to Romo RMMs as well as utilisation patterns of Romo and other OP medications (including persistence and switching/transition patterns) in Europe.

Materials and Methods: This multi-national, multi-database cohort study was conducted using routinely collected healthcare data from Denmark, Germany, the Netherlands, Spain, and the UK. Adult patients (≥18 years) initiating Romo or other OP medications between 2018–2025 were identified for patient-level analyses. Prevalence and incidence rates of Romo use were calculated, and compliance with RMMs was assessed by evaluating the proportion of Romo users with contraindications (history of MI or stroke) and those meeting the indicated population (women ≥50 years with recent fracture).

Results: A total of 2,501 patients initiated Romo. Across databases, monthly treatment prevalence ranged from 0.04 to 0.44 per 10,000 persons, and monthly incidence from 0.01 to 0.05 per 10,000 person-months. Most Romo users were female (98–99%) and aged ≥50 (98–100%), with 27–90% across databases having a record of fracture within two years before treatment (variation potentially reflecting databases ability to capture fracture history). History of MI was present in 0–1.8% of Romo users (vs 2.4–7.2% for other OP drugs), and history of stroke in 0–3.7% (vs 5.1–9.5%). Median medication possession ratio was high in Germany and Spain (99%), but lower elsewhere due to prescription tracking limitations of databases. Romo switching mainly occurred between 12–18 months (matching the recommended course), most often to antiresorptives (denosumab, bisphosphonates), as per guidelines.

Conclusions: Adherence to RMMs for Romo appears to be generally high in Europe, with most users meeting label criteria and few with contraindications. Final results of this study are expected next year with larger sample size and longer follow-up.

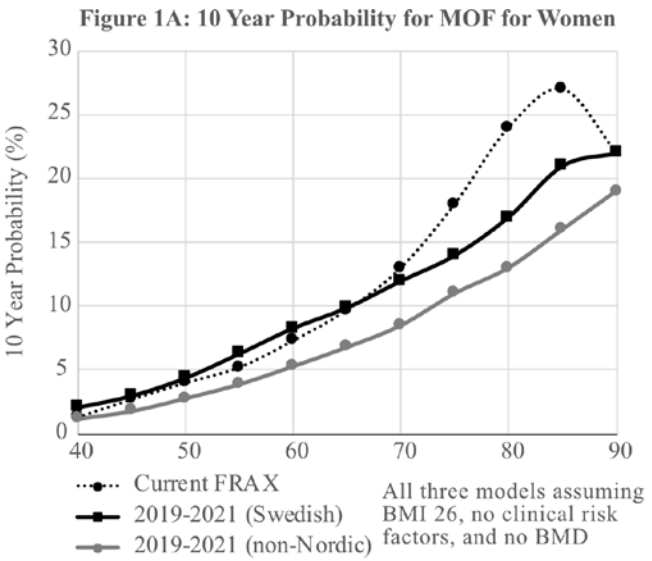
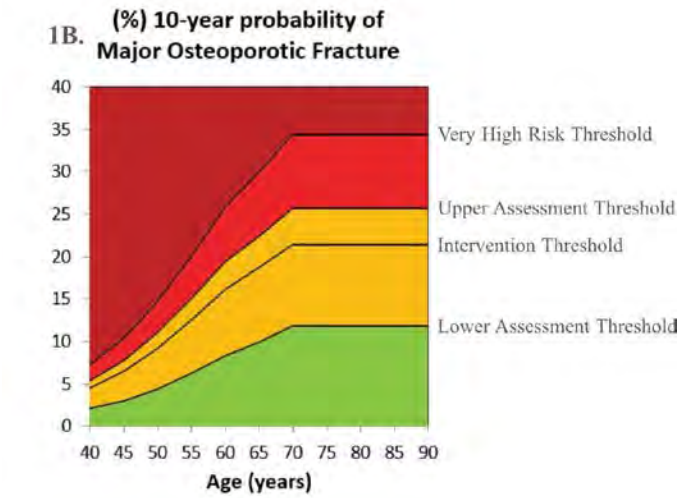
REVISED SWEDISH FRAX MODELS AND THE ESTABLISHMENT OF AGE-DEPENDENT INTERVENTION THRESHOLDS

K. F. Axelsson[1], H. Litsne[1], N. C. Harvey[2], J. A. Kanis[3], E. McCloskey[4], H. Johansson[1], M. Lorentzon[1]



[1]Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, Sahlgrenska University Hospital, Mölndal, Sweden; [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southhampton, United Kingdom; [3]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [4]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom



Objective: Since the development of the Swedish FRAX model in 2008, fracture incidence has changed. The primary aim of this study was to develop a revised FRAX model, based on region of birth, and updated incidence for death and fracture, for Sweden. A secondary aim was to define age-dependent intervention thresholds.

Methods: Based on national registries, all persons from the age of 40 years living in Sweden between 2005 and 2021 were included. Yearly age- and sex-standardized incidence of hip fracture and major osteoporotic fracture (MOF) were calculated, and those from 2019-2021 were used to create a revised FRAX model for Sweden. Two models, one for Swedish/Nordic born individuals and one for non-Nordic born, were developed. We compared the revised FRAX models with the original model. In addition, we calculated age-specific intervention thresholds for BMD testing and treatment using the methods of the UK National Osteoporosis Guideline Group. We then compared the number of patients eligible for intervention with the revised FRAX models and age-dependent thresholds with the original FRAX model and fixed threshold by age-group and sex in a simulated Swedish population.

Results: Compared with the previous FRAX model, the revised model yielded lower 10-year probabilities for both hip fracture and MOF in men and women. The non-Nordic models showed substantially lower probabilities across all age groups and sexes (Figure 1A). Intervention thresholds for MOF without BMD ranged from a ten-year probability of 4.5% at age 40 years to 21.5% at age 70 years and older (Figure 1B). Given similarities between the previous and new fixed probability thresholds in men and women 70 years and older, the proportion with probabilities above the thresholds was also similar. However, the proportions of younger women and men with probabilities above the age-dependent thresholds were 3.5 and 7.1 times higher compared to the respective fixed thresholds.

Conclusions: The revised FRAX models update the calibration of the models for current fracture incidences, with lower risk estimates for older people. However, the introduction of age-dependent intervention thresholds increases the eligibility of younger patients for osteoporosis treatment in Sweden.

IMPROVED 10-YEAR FRACTURE RISK PREDICTION WITH THE "BONE STRAIN INDEX" BEYOND BONE MINERAL DENSITY AND FRAX® IN COMMUNITY-DWELLING OLDER WOMEN

J. M. K. De Filette[1], A. Bellanger[2], L. Rinaudo[3], F. M. Ulivieri[4], I. Calderone[3], S. Cuttone[3], D. Sanchez-Rodriguez[5], F. Baleanu[1], A.-S. Hambye[6], F. Benoit[5], M. Surquin[5], L. Iconaru[1], J.-J. Body[1], P. Bergmann[6]

[1]Endocrinology, CHU Brugmann, Brussels, Belgium; [2]Translational Research Unit, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; [3]Tecnologie Avanzate T.A. SRL, Turin, Italy; [4]Bone Metabolic Unit, Casa di Cura La Madonnina, Gruppo San Donato, Milan, Italy; [5]Geriatrics, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; [6]Nuclear Medicine, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium

Objectives: The Bone Strain Index (BSI), derived from finite element analysis of DXA, quantifies mechanical strain within bone. Its predictive value for fragility fractures in older women remains to be established in large prospective studies.

Methods: This prospective cohort study assessed the association between BSI, incident and major osteoporotic fractures (MOF) in 3338 community-dwelling older women (age 64-77 years) during a 5-year and 10-year follow-up. BSI was calculated at the lumbar spine, total hip, and femoral neck using baseline DXA scans. Incident fragility and MOF were radiographically validated. Discriminative performance was assessed using ROC curves, optimal cut-offs (Youden index), and Cox proportional-hazards models adjusted for age, areal bone mineral density (aBMD), or FRAX® score.

Results: During the 10-year follow-up, 803 women (24.1%) sustained at least one fragility fracture, including 525 MOF. Higher BSI values were significantly associated with increased fracture risk at 5 and 10 years, independently of age, aBMD, or FRAX®. Total hip BSI showed the strongest performance among all sites (AUC 0.63 at 5 and 10 years), outperforming lumbar spine BSI (AUC 0.58). Each 1-SD increase in total hip BSI was associated with higher fracture risk (HR 1.42 [1.32–1.53] at 5 years; 1.41 [1.34–1.49] at 10 years), which remained significant after FRAX® adjustment (HR 1.24 [1.14–1.35]).

Conclusions: BSI independently predicted incident fragility fractures and MOF during a 5-year and 10-year follow-up in community-dwelling older women. Total hip BSI showed stronger predictive performance than lumbar spine BSI, and both provided discriminative value beyond aBMD and FRAX®.

EROSIVE HAND OSTEOARTHRITIS IS ASSOCIATED WITH INCREASED RISK OF INCIDENT OSTEOPOROTIC FRACTURES IN POST-MENOPAUSAL WOMEN (QUALYOR COHORT)

M. A. Auroux[1], A. Mercier-Guery[1], A. Piot[2], B. Merle[3], M. Proriol[1], E. Fontanges[1], E. Duvert[1], E. Lespessailles[4], R. Chapurlat[1]

[1]Hospices Civils de Lyon, Lyon, France; [2]Centre Hospitalier Lucien Hussel, Vienne, France; [3]INSERM U1033, Lyon, France; [4]Centre Hospitalier Universitaire d'Orléans, Orléans, France

Purpose :

Erosive hand osteoarthritis (ErHOA) is a severe form of hand osteoarthritis (HOA) associated with greater inflammation and disability. Previous studies exploring the relationship between osteoarthritis and the incidence of osteoporotic fractures have yielded inconsistent results, and data specifically on hand OA are limited. We aimed to investigate the association between ErHOA, bone loss, and the incidence of osteoporotic fractures.

Methods:

We used data from the prospective **QUALYOR** study, which enrolled 1,575 postmenopausal women aged at least 50 years, followed prospectively for 14 years. At baseline (the 6-year visit), HOA was assessed using hand radiographs and the AUSCAN questionnaire. Hand osteoarthritis status was defined as follows:

- **No HOA:** no pain **and** no radiographic sign of HOA
- **Radiographic HOA (RxHOA):** at least two joints graded KL ≥ 2 **and** no symptoms
- **Symptomatic HOA (SHOA):** ACR criteria for HOA (no eroded joints)
- **Erosive HOA (ErHOA):** SHOA with at least one eroded joint

Osteoporotic (OP) status was also evaluated at baseline and each follow-up visit by DXA (Bone Mineral Density [BMD] at the lumbar spine and hip), and incident OP fractures were medically ascertained. OP status was defined as follows:

- **No OP:** all T-scores above −2.5 **and** no history of OP fracture
- **OP DXA:** at least one T-score below −2.5 **and** no history of OP fracture
- **OP fracture:** history of at least one OP fracture (regardless of T-scores)

Associations between baseline HOA status and incident OP fractures were analyzed using Cox proportional hazards models adjusted for age, fracture history, T-scores, obesity, and SPPB score (a surrogate marker of sarcopenia). Kaplan–Meier curves and standardized incidence rates (SIRs, Poisson regression) were obtained. Linear mixed-effects models adjusted for age and BMI assessed annual BMD changes according to HOA status. A mediation analysis evaluated the impact of ErHOA on incident fractures, with mediators selected among major fracture risk factors (age, T-scores, prevalent fracture at baseline, SPPB score).

Results :

The analysis included 1,180 women (mean age 71.7 ± 6.4 years; mean follow-up 4.6 ± 0.9 years): 364 (30.8%) had no HOA, 335 (28.4%) RxHOA, 340 (28.8%) SHOA, and 141 (11.9%) ErHOA. Participants with ErHOA were significantly older, more obese, and more sarcopenic (lower SPPB scores) than controls.

During follow-up, 131 participants (11.1%) experienced 166 incident OP fractures, with a mean time to event of 2.2 ± 1.42 years. Among them, 19.1% had ErHOA compared with 11.1% among those without incident fractures ($p < 0.05$).

The age-standardized incidence rate of OP fractures was **58.5/1,000 patient-years** (95% CI [16.6–155.7]) in ErHOA versus **30.2/1,000 patient-years** (95% CI [10.9–66.6]) in participants without HOA or with non-erosive HOA.

The hazard ratio (HR) for incident fracture in ErHOA compared with no HOA was **1.93** (95% CI [1.12–3.32], $p < 0.05$), whereas HRs were **1.10** (95% CI [0.69–1.77], n.s.) for SHOA and **0.95** (95% CI [0.59–1.57], n.s.) for RxHOA.

Additional stratification by prevalent fracture history at baseline (a major risk factor for subsequent OP fractures) again showed the highest fracture incidence rates in ErHOA patients.This increased fracture risk was not mediated by greater bone loss over time.

Mediation analysis supported a predominant direct effect of ErHOA on fracture risk, outweighing all other mediators (direct effect = 0.379, $p = 0.016$).

Conclusions :

Erosive HOA is a strong predictor of incident osteoporotic fractures in postmenopausal women, independently of classical fracture risk factors.

These findings suggest that ErHOA represents a distinct endotype of HOA (since the association was not significant for other HOA phenotypes), and the mechanisms underlying this association warrant further integrated investigation.

MUSCULOSKELETAL HEALTH AND LIFE-SPACE MOBILITY, SOCIAL ISOLATION AND LONELINESS IN THE OLDEST OLD: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], G. Bevilacqua[1], H. P. Patel[1], F. Laskou[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective

Musculoskeletal conditions, and their related adverse events such as falls and fractures, are prevalent among the oldest old (>80 years) and affect functional ability and quality of life. However, research on how these factors relate to life-space mobility (extent, frequency, and independence with which an individual moves through their environment), social isolation, and loneliness in this age group is limited. We investigated this in community-dwelling older adults from the Hertfordshire Cohort Study.

Materials and Methods

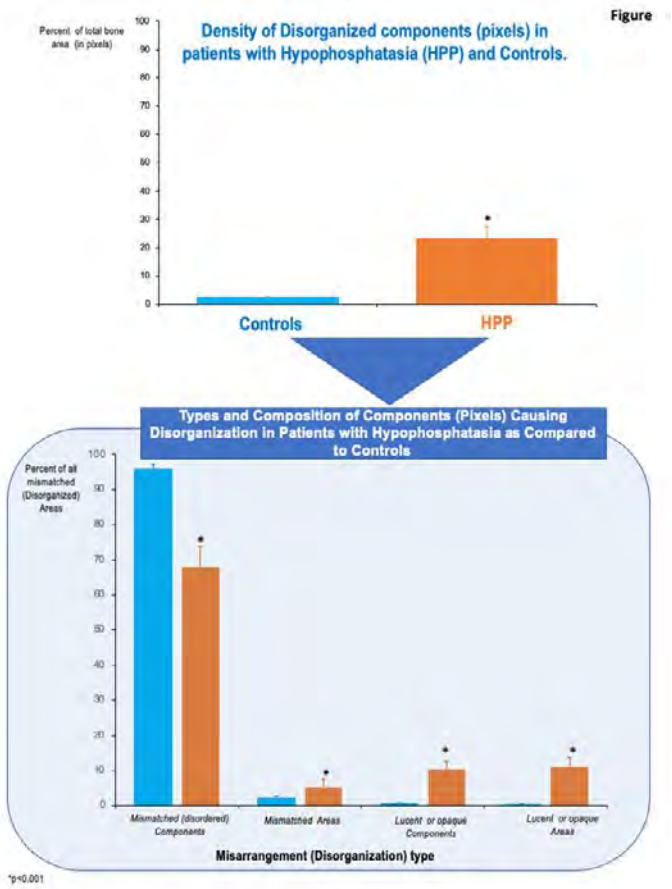
Data were analysed from 169 men and 156 women aged 84–93. Participant information was collected using self-administered questionnaires. Exposures included: fall in previous year; fracture since age 50; osteoarthritis (self-reported diagnosis or history of hip/knee arthroplasty); and high sarcopenia risk (≤52.4 on the Sarcopenia Quality of Life [SarQoL] questionnaire). Outcomes included: University of Alabama Life-Space Assessment (LSA) score, social isolation score (Lubben Social Network Scale), and De Jong Gierveld loneliness scores (emotional, social, overall). Sex-stratified linear and Poisson regression models were implemented. Age, ability to manage financially, nutritional risk score, physical activity, and number of systems medicated were included as adjustments.

Results

Musculoskeletal exposures were common: falls (men 36.1%, women 34.9%); fractures (men 14.2%, women 28.8%); osteoarthritis (men 36.3%, women 61.0%); and high sarcopenia risk (men 21.7%, women 43.0%). Compared to those without the exposure, lower mean LSA scores (95% CI) were observed among men who reported a fall (−9.7 (−18.8, −0.6)) and among participants with high sarcopenia risk (men −26.6 (−35.9, −17.3), women −17.9 (−25.6, −10.2)). Emotional loneliness scores were 2.4 (1.4, 4.2) times higher among women with high sarcopenia risk compared to those without; p>0.05 for other associations.

Conclusion

Musculoskeletal conditions and adverse outcomes were common. High sarcopenia risk was related to greater emotional loneliness among women, and lower LSA scores among both sexes. These findings suggest that individuals at high sarcopenia risk may be at increased risk of poor life-space mobility and loneliness, and could benefit from personalised support and health interventions.



OC11

BONE COMPONENT DISORGANIZATION IN METABOLIC AND GENETIC BONE DISEASES, INCLUDING HYPOPHOSPHATASIA: NOVEL INSIGHTS INTO DISEASE PATHOGENESIS AND PATIENT ASSESSMENT

R. Zebaze[1], C. Chiang[2], C. Shore-Lorenti[1], F. Milat[3], R. Ebeling[1]

[1]School of Clinical Sciences, Monash University, Melbourne, Australia, Melbourne, Australia; [2]Department of Endocrinology, Austin Health, University of Melboune, Melbourne, Australia; [3]Hudson Institute of Medical Research Adjunct Associate Professor, School of Clinical Sciences, Monash University, Melbourne, Australia

Figure

Background: In metabolic and genetic bone diseases, bone cell function may be impaired, or cells may receive incorrect or abnormal matrix components. As a consequence, inappropriate components may be deposited within the bone matrix, or normal components may be deposited in incorrect locations, leading to a misarranged (disorganized) bone matrix—a major clinical and biomechanical abnormality. Disruption of the normal organization of matrix elements impairs load and energy transfer, resulting in structural damage, skeletal abnormalities, and fractures, independently of bone mineral density (BMD).

Hypophosphatasia (HPP) represents a prototypical disorder in which these mechanisms are prominent. In HPP, deficiency or dysfunction

of tissue-nonspecific alkaline phosphatase (TNSALP) leads to the accumulation of abnormal matrix components and consequent bone matrix disorganization. We therefore hypothesized that quantifying the extent of bone matrix misarrangement could provide a robust approach for identifying and assessing patients with HPP in both clinical and research settings.

Methods- We studied 29 patients with adult-onset hypophosphatasia (HPP) and 103 age- and sex-matched controls. The extent of bone matrix disorganization and the characteristics of the most misarranged areas were assessed on femoral X-rays using a novel, validated tool (ALIGNOGRAM).

Findings- In patients with HPP, 235.48 ± 3.97 out of 1,000 matrix components (pixels) were disorganized, compared to 27.85± 0.27 in controls (p<0.0001)—representing an 8.45-fold greater degree of misarrangement.

Remarkably, in all patients with HPP, disorganization was attributable to the presence of lucent (hypodense) or opaque (hyperdense) components—a feature observed in less than 1% of controls. In contrast, among controls, disorganization was predominantly due to mismatched or disorderly arranged components (pixels), which represented the sole abnormality in 95.7% ± 1.26 of them (Figure).

Interpretation: The presence of a disorganized bone matrix characterized by lucent (hypodense) and/or opaque (hyperdense) elements should alert health professionals to an underlying genetic or metabolic bone disease, especially HPP. This imaging biomarker, which can be quantified on standard plain radiographs available worldwide, provides a widely accessible and cost-effective approach for early detection, routine monitoring, and assessment of therapeutic response, particularly in patients with metabolic, genetic, and other rare bone diseases, including HPP.

Objective: To assess frequency of renal and eye ectopic calcifications among patients with hypophosphatasia (HPP) who were either naive to treatment or treated with asfotase alfa enzyme replacement therapy (ERT).

Methods: Patients of all ages enrolled in the Global HPP Registry were included. Frequencies (95% CIs) of nephrocalcinosis and eye ectopic calcifications were assessed by renal ultrasound and ophthalmologic exam, respectively. Assessments were cross-sectional in ERT-naive patients (at any time in untreated patients or before ERT in treated patients) and longitudinal in treated patients. Patients in Japan were excluded from eye analyses owing to differences in data collection. Data cut: June 2025.

Results: A total of 1,155 patients were included (65.9% female, 70.6% White, median age 32.3 y at last ERT-naive visit, 42.3% went on to ERT). Nephrocalcinosis was found in 12.5% (64/513; 95% CI 9.7%, 15.7%) of ERT-naive patients; most (76.7% [33/43]) cases were mild. Nephrocalcinosis was more common in patients who went on to receive ERT (17.3% [39/225]; 95% CI 12.6%, 22.9%) than those who never received ERT (8.7% [25/288]; 95% CI 5.7%, 12.5%). Eye ectopic calcification was found in 4.2% (9/214; 95% CI 1.9%, 7.8%) of ERT-naive patients. Of 488 treated patients, 150 had a renal ultrasound and 66 had an eye exam before and after ERT start. Nephrocalcinosis occurred in 22.7% (95% CI 16.2%, 30.2%) of patients at or before ERT, 27.3% (95% CI 20.4%, 35.2%) at any time after ERT, and 14.7% (95% CI 9.4%, 21.4%) at most recent exam (median [range] follow-up: 4.2 [0.3, 12.9] y); eye ectopic calcification was found in 4.5% (95% CI 0.9%, 12.7%), 16.7% (95% CI 8.6%, 27.9%), and 4.5% (95% CI 0.9%, 12.7%) of patients, respectively (median [range] follow-up: 5.0 [0.5, 12.9] y).

Conclusions: Ectopic calcifications were reported in ERT-naive patients, indicating they are part of HPP's natural history. ERT does not appear to increase ectopic calcification occurrence in longitudinally followed patients.

INCIDENCE OF NEW OSTEOPOROTIC FRACTURES UP TO THREE YEARS OF FOLLOW-UP IN SUBJECTS WITH TYPE 2 DIABETES MELLITUS WHO INITIATE ANY OSTEOPOROSIS MEDICATION COMPARED TO NON-DIABETICS: A POPULATION-BASED COHORT STUDY

L. Gomez Rodriguez[1], C. Carbonell-Abella[1], P. Satorra Herbera[2], C. Reyes[3], M. A. Pou Gimenez[1], C. Diaz Torné[4], D. Martinez-Laguna[1], C. Tebé-Cordomí[2]

[1]Primary Care. Institut Català de la Salut. GREMPAL Research Group, Jordi Gol Institute for Primary Care Research (IDIAP), Autonomous University of Barcelona, Barcelona, Spain; [2]Biostatistics Support and Research Unit, Germans Trias i Pujol Research Institute and Hospital (IGTP), Barcelona, Spain; [3]Sardenya Primary Health Care Center, EAP Sardenya- Research Institute Sant Pau (EAP Sardenya-IR Sant Pau), Barcelona, Spain, Barcelona, Spain; [4]Rheumatology Department, Hospital de Sant Pau, Barcelona, Spain

Introduction: Patients with type 2 diabetes mellitus (T2DM), despite having higher bone mass than the general population, have an increased risk of osteoporotic fractures (OF). In addition, these patients are underrepresented in clinical trials of different osteoporosis medications (OM).

Objective: To analyze the incidence of OF among patients with T2DM compared to non-diabetics in real-life conditions.

Methods: A population-based cohort study in the primary care setting was conducted. All individuals who initiated an OM between 2012 and 2016 were selected from the SIDIAP database (which contains pseudo-anonymized clinical information on more than 5.5 million patients in Catalonia). Exclusion criteria included prior OM use in the previous 12 months, history of neoplasia, Paget's disease, or HIV infection. Up to three non-diabetic subjects were matched to each T2DM subject by propensity score. To assess effectiveness, incidence rates and incidence rate ratios of hip fracture (HF), vertebral fracture (VF) and OF were calculated for the periods 0-3, 4-12, 13-24 and 25-36 months.

Results: A total of 42,946 subjects who initiated an OM were identified (5,828 with T2DM and 37,118 non-diabetic), predominantly women (82.5% in T2DM and 91.6% in non-diabetics), with a mean age (SD) of 74.1 (8.9) and 68.1 (10.4) years, respectively. The most used OM were oral bisphosphonates (80.4%) and denosumab (9.8%). Incidence rates (×1000 person/year) in subjects with T2DM were 53.7 for OF, 18.7 for HF, and 32.8 for VF, and in non-diabetic subjects 31.5, 8.1 and 22.5, respectively. Compared with the 0–3 months period, incidence rate ratios for all OM were lower in all subsequent periods, both in T2DM and non-diabetic subjects (Table 1).

Conclusions: The effectiveness of different OM, measured as changes in incidence rates, is similar in patients with T2DM and in non-diabetic individuals.

Table 1: Incidence rate ratios (95% CI) for different OM in T2DM and non-diabetic subjects, compared to the 0-3 months period.

TYPE 2 DIABETES MELLITUS AND FRACTURE RISK: AN INTERNATIONAL META-ANALYSIS

N. C. Harvey[1], E. M. Curtis[1], H. Johansson[2], L. Westbury[1], E. V. McCloskey[3], E. Liu[4], L. Vandenput[5], D. P. Kiel[6], M. Lorentzon[7], W. D. Leslie[8], J. A. Kanis[2], .. Frax Meta-Analysis Cohort Group[2]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [3]MRC Versus Arthritis Centre for Integrated research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom; [4]South Australian Health and Medical Research Institute (SAHMRI), Adelaide, Australia; [5]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Gothenburg, Sweden; [6]Marcus Institute for Aging Research, Hebrew Senior Life, Boston, United States; [7]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; [8]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objectives

We investigated, using an international individual participant data meta-analysis, prospective associations between type 2 diabetes mellitus and incident fracture in men and women, and any dependence of associations on femoral neck bone mineral density (FNBMD).

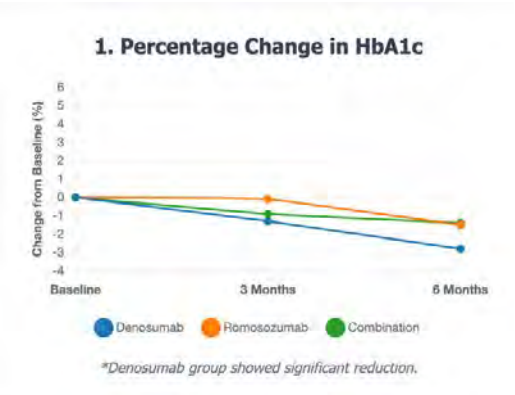
Materials and methods

The interim analysis dataset comprised individual records of 951,871 participants (65.0% women) with information on type 2 diabetes status, from 48 cohorts across 31 countries. The total follow-up time was 10.2 million person-years. FNBMD T-score was available in a subset of 134,817 individuals. We investigated associations between the presence/absence of type 2 diabetes mellitus at baseline and risk of major osteoporotic fracture (MOF) or hip fracture using an extended Poisson model in each cohort. Covariates considered were age, sex, duration of follow-up and FNBMD T-score. The results from the different studies were merged by using the inverse-variance weighted β-coefficients in a random effects model.

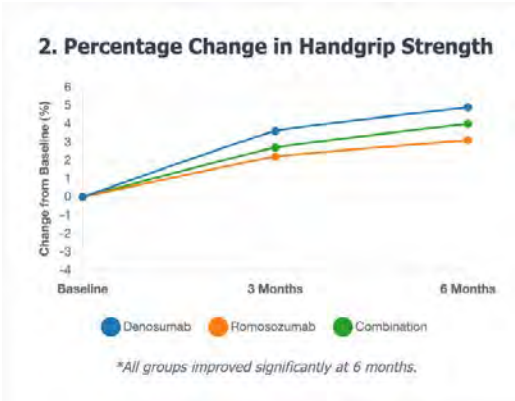
Results

In a model adjusted for age and time since baseline, type 2 diabetes was associated with a greater risk of incident MOF in both men [hazard ratio (95% CI): 1.20 (1.11, 1.33)] and women [1.11 (1.03, 1.19)]. Comparable associations were demonstrated for hip fracture [men: 1.29 (1.16, 1.44); women: 1.43 (1.23, 1.66)]. Associations were similar in the subset with FNBMD; adjustment for FNBMD T-score tended to modestly increase point estimates. For example, for incident hip fracture: men, 1.71 (1.44, 2.03); women, 1.48 (1.24, 1.78).

Conclusions



In one of the largest ever individual participant data meta-analyses undertaken to date, type 2 diabetes was associated with increased fracture risk, at least partly independently of femoral neck BMD. These findings will inform the next iteration of the FRAX® calculator.



OC15

LONGITUDINAL EFFECTS OF DENOSUMAB, ROMOSOZUMAB, AND COMBINATION THERAPY ON MUSCLE QUALITY AND METABOLIC PROFILES A RANDOMIZED CONTROLLED TRIAL

H. K. Yen[1], J. Y. Hsu[2], S. H. Fu[3], C. C. Hung[4], C. Y. Wang[5]

[1]Department of Orthopaedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan, Taipei, Taiwan; [3]Department of Orthopaedic Surgery, National Taiwan University Hospital, Yunlin, Taiwan; [4]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [5]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

OBJECTIVE(S): To compare the efficacy of denosumab, romosozumab, and their combination on musculoskeletal health (handgrip strength, skeletal muscle mass) and metabolic profiles (HbA1c, body composition) in osteoporotic patients.

MATERIAL AND METHODS: A total of 114 patients were randomized into three groups: denosumab (N=38), romosozumab (N=38), and combination therapy (denosumab + romosozumab, N=38). Outcomes included handgrip strength, skeletal muscle mass (SMM), fat mass, BMI, and HbA1c, assessed at baseline, 3, and 6 months. Changes from baseline were analyzed. Statistical methods included Kruskal-Wallis for between-group differences, Friedman test for within-group longitudinal changes, and Generalized Estimating Equations (GEE) for time-by-group interactions.

RESULTS: Baseline characteristics were comparable across groups ($p>0.05$). GEE analysis showed no significant time-by-group interactions for any outcome, indicating parallel improvement trends across treatments. No significant between-group differences were found in percentage changes at 3 or 6 months. However, within-group analyses revealed significant improvements. At 6 months, handgrip strength increased in all groups (denosumab: +4.9%; romosozumab: +3.1%; combination: +4.0%; all $p<0.05$). SMM also significantly increased (denosumab: +1.6%; romosozumab: +1.0%; combination: +1.1%; $p<0.05$). Uniquely, regarding metabolic profiles, only the denosumab group showed a significant reduction in HbA1c (-2.8%, $p=0.015$), whereas other groups showed no significant change.

CONCLUSION(S): All three regimens—denosumab, romosozumab, and combination therapy—effectively improved muscle quality (strength and mass) over 6 months, with no significant difference between strategies. Notably, denosumab monotherapy conferred an additional benefit in glycemic control (HbA1c reduction), suggesting potential metabolic advantages beyond skeletal protection.

OC16

PREGNANCY-RELATED CHANGES IN BONE HEALTH: A LONGITUDINAL REMS-BASED STUDY

V. A. Degennaro[1], S. Casciaro[2], F. Conversano[2], F. A. Lombardi[2], G. Peluso[3], P. Pisani[2], T. Ghi[4]

[1]Department of Medicine and Surgery, Unit of Obstetrics and Gynecology, University of Parma, Parma, Italy; [2]Institute of Clinical Physiology, National Research Council, Lecce, Italy; [3]Department of Innovative Enginnering, University of Salento, Lecce, Italy; [4]Policlinico Gemelli, Catholic University of the Sacred Heart, Roma, Italy

SC, FC, FAL, GP and PP equal contributors in alphabetic order

Objective(s): Pregnancy-related increases in calcium requirements may lead to enhanced bone resorption, resulting in substantial reductions in bone mineral density (BMD), and a higher risk of osteoporosis. Current evidence in literature report that pregnant women can show a BMD reduction up to 9%. As standard densitometric technologies, such as dual-energy X-ray absorptiometry (DXA), involve exposure to ionising radiation, their use is not recommended during pregnancy. Therefore, the present study aimed to investigate pregnancy-related changes in bone density and microarchitecture using the Radiofrequency Echographic Multi-Spectrometry (REMS) technology.

Materials and Methods: Inclusion criteria encompassed Caucasian pregnant women at first trimester who underwent REMS scans of femoral neck. Patients were re-assessed at the third trimester. By automatically combining bone quantity (REMS-T-score) and quality (REMS-FS) parameters, patients were classified into one of the 7 risk classes (named from R1 to R7), each corresponding to an increasing probability of imminent (within 5-year) fragility hip fractures. Changes in bone-related parameters over time were evaluated using paired *t*-tests.

Results: In total, the analysis included 46 pregnant women (aged 26–49 years; BMI 16.59–29.76 kg/m²). Comparison over time revealed a significant deterioration in both bone-related parameters: the mean T-score, in fact, decreased from −1.1 ± 0.7 to −1.3 ± 0.7 ($p < 0.0001$), and the mean FS increased from 41.70 ± 5.68 to 46.39 ± 8.33 ($p = 0.0006$). Furthermore, 55% of the participants shifted from a lower to a higher risk class.

Conclusion(s): Overall, the results demonstrate that pregnancy is associated with a deterioration in bone density and microarchitectural integrity, which together increases the risk of fragility fractures. In this context, REMS technology represents a safe, radiation-free and non-invasive approach that enables early identification of women at higher risk and monitoring over time, thus supporting targeted preventive strategies.

OC17

COST-EFFECTIVENESS OF AI-ENHANCED OPPORTUNISTIC OSTEOPOROSIS SCREENING USING CHEST RADIOGRAPHS: EVIDENCE FROM SIX INTERNATIONAL ANALYSES

M. Hiligsmann[1], M. Alokail[2], J.-Y. Reginster[2]

[1]Maastricht University, Maastricht, Netherlands; [2]King Saud University, Riyadh, Saudi Arabia

Introduction: AI-enhanced analysis of routinely acquired chest radiographs enables opportunistic osteoporosis screening without additional imaging. While individual studies suggest economic value, evidence comparing results across healthcare systems is limited. This study summarizes findings from six international cost-effectiveness analyses of AI-enhanced opportunistic osteoporosis screening.

Methods: We reviewed six country-specific studies, four published and two recently submitted, comparing AI-enhanced chest radiograph screening with no screening. Models used local data on fracture incidence, costs, follow-up pathways, and treatment patterns. Outcomes included costs, quality-adjusted life years (QALYs), incremental cost-effectiveness ratios (ICERs), and key drivers.

Results: AI-enhanced screening was cost-effective in all six settings (Germany, United States, Japan, Korea, Singapore, Australia). ICERs ranged from dominance (cost-saving with QALY gains) to US$72,085 per QALY gained. Dominance occurred in some settings, largely where fracture incidence or fracture-related costs were higher. Lifetime fractures prevented per 10,000 screened people ranged from 16 (Singapore) to 44 (Germany). One evaluation (Korea) included both sexes and showed cost-effectiveness in men and women. Across countries, results were most sensitive to fracture costs, medication prices, adherence, and follow-up after osteoporosis is suspected.

Discussion: Across diverse healthcare systems, AI-enhanced opportunistic screening consistently produced favorable economic outcomes, though the size of benefit varied. Differences in epidemiology, treatment patterns, and cost structures limit direct generalizability, highlighting the need for local analyses. Overall, these findings support AI-enhanced opportunistic screening as a scalable and efficient strategy to reduce the global burden of osteoporotic fractures.

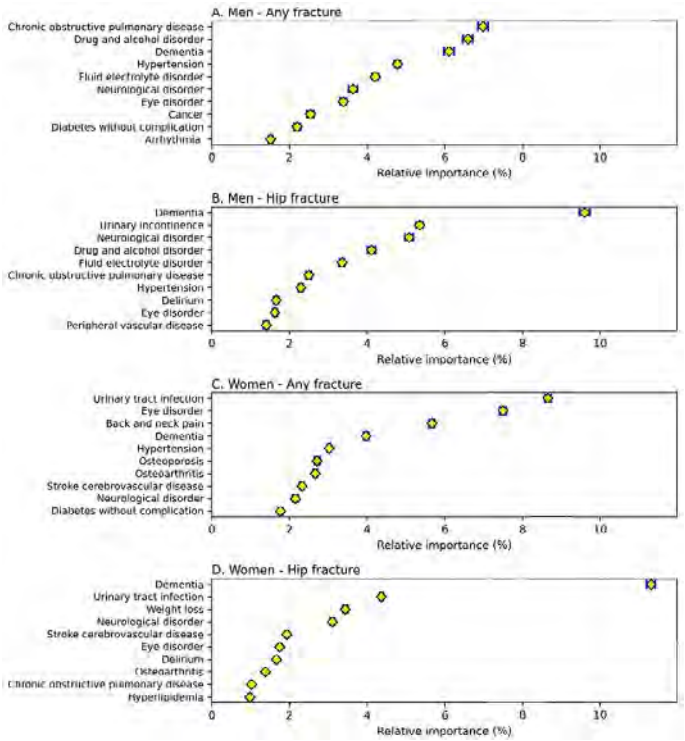
CLINICALLY INTERPRETABLE PREDICTORS OF IMMINENT SUBSEQUENT FRACTURES IN A DEEP-LEARNING PREDICTION MODEL

H. Nguyen[1], T. Tran[1], D. Bliuc[1], R. Blank[1], C. White[1], J. Center[1]

[1]Skeletal Diseases Program, Garvan Institute of Medical Research, Sydney, Australia



The inherent *"black-box"* nature of machine- and deep-learning models, despite the reported superiority in predictive performance, limits their adoption in clinical practice, as clinicians cannot justify individual predictions necessary for personalised treatment decisions. This study aimed to quantify and characterise the relative importance of predictors in a deep-learning algorithm for imminent subsequent fracture risk, facilitating its clinical interpretability and translational potential.

We developed a *DeepHit* prediction model for subsequent fractures using administrative health data from a statewide population-based cohort of 269,294 adults in New South Wales, Australia, born on or before 01/01/1950, who sustained an incident fracture between 2005 and 2017, with follow-up through 2022. The model accounts for complex non-linear data and competing mortality risks. Predictors included age at index fracture, fracture site, prior fractures and falls, and 1,870 ICD-10 codes representing 65 predefined chronic diseases recorded at the time of the index fracture. We used a SHapley Additive exPlanations (SHAP) to quantify each predictor's contribution across all possible predictor subsets.

The model showed strong discrimination and calibration for 1- and 2-year risks of subsequent fractures, with minimal prediction bias (~ zero), and C-indices of up to 0.81 for hip fractures and 0.75 for any subsequent fractures. Age at index fracture was the dominant predictor, accounting for 20% of the predictive contribution for any subsequent fractures in men and up to 34% for hip fractures in women. Index fracture site was consistently influential, contributing 8-14% of the overall model predictive performance. Among comorbidities, lung disease, dementia, urinary tract infections or incontinence, drug- or alcohol-related disorders, eye and neurological conditions were the strongest contributors to the prediction of imminent subsequent fracture risk (Figure).

This study identifies clinically meaningful predictors of imminent subsequent fractures. It demonstrates that explainable deep-learning models can provide accurate predictive performance while remaining interpretable and transparent, thus supporting targeted secondary fracture prevention.

Figure. The strongest comorbidity predictors to imminent subsequent fracture risk

HIGH MORTALITY IN OLDER MEN WITH LOW MUSCLE MASS AND STRENGTH – THE PROSPECTIVE STRAMBO STUDY

P. Szulc[1], R. Chapurlat[1]

[1]INSERM UMR 1033, University of Lyon, Hospices Civils de Lyon, Lyon, France

Objective: Low muscle mass and strength are associated with high mortality, but the studies were focused on all-cause mortality and did not consistently assess predictive value of both factors. We assessed the association of low muscle mass (estimated by the creatinine to cystatin C ratio [CCR]) and grip strength with the mortality in older men.

Methods: In 806 men aged 60–87 yr, grip strength and CCR were assessed at baseline. Data on the death (date, cause) was confirmed by a health professional. Statistical models were adjusted for age, fat mass, education level, physical activity, co-morbidities, 25OHD, C-reactive protein, eGFR and abdominal aortic calcification.

Results: Over 12 years, 255 men died. Among them, 69 died of cardiovascular (CV) diseases, 88 of cancer and 98 of other reasons (non-CV-non-cancer mortality). CCR and grip strength were correlated ($r=0.22$, $p<0.001$). Low CCR and low grip strength were associated with higher all-cause mortality (HR=1.39 /SD decrease, 95%CI: 1.20–1.62, and HR=1.37 /SD decrease, 95%CI: 1.16–1.61, both $p<0.001$) independently of each other (interaction, $p=0.93$). Mortality was higher in men being in the lowest tertiles of CCR and grip strength vs. those being in the highest tertiles of both variables (HR=5.47, 95%CI: 2.59–11.57, $p<0.001$).

CCR and grip strength were associated with higher CV mortality (HR=1.57 /SD, 95%CI: 1.17–2.11, $p<0.005$ and HR=1.52 /SD, 95%CI: 1.10–2.11,

p<0.05) and higher non-CV-non-cancer mortality (HR=1.59 /SD, 95%CI: 1.22–2.07 and HR=1.64 /SD, 95%CI: 1.25–2.14, both p<0.001). Only CCR was associated with cancer mortality (p<0.005). Each type of mortality was higher in men in the highest tertiles of both variables vs. men in their lowest tertiles (e.g., cancer mortality HR=12.29, 95%CI: 2.64-57.20, p<0.005).

Conclusion: In older men followed prospectively for 12 years, low muscle mass (estimated by CCR) and, to a lesser extent, low grip strength were associated with higher mortality regardless of its cause.

OC20

LOWER INTRINSIC CAPACITY AND SARCOPENIA: DATA FROM THE GEELONG OSTEOPOROSIS STUDY

J. A. Pasco[1], A. L. Stuart[1], K. B. Anderson[1], K. L. Holloway-Kew[1], E. C. Emma[1], L. J. Williams[1]

[1]Impact Institute, Deakin University, GEELONG, Australia

Objective: Intrinsic capacity (IC), proposed by the WHO as the overall combination of an individual's physical and mental abilities, has been identified as a key indicator of healthy ageing. While the Integrated Care for Older People (ICOPE) framework focuses on overall IC, it includes aspects of ageing which are also relevant to sarcopenia. The aim of this cross-sectional study was to explore the IC-sarcopenia relationship in older women.

Methods: Composite IC scores were calculated for 191 women (60-90y), with higher scores reflecting greater capacity, based on five domains: vitality (repeated chair stands, perceived energy, weight loss), cognition (Mini-Mental State Examination), psychological wellbeing (Hospital Anxiety and Depression Scale), locomotion (timed Up-&-Go) and sensory abilities (vision, hearing). Scores for each domain ranged from 0 (unhealthy) to 3 (healthy). Low appendicular lean mass (ALM/h^2<5.5kg/m^2) was measured by DXA and low handgrip strength (HGS<16kg) by dynamometry. Education, physical activity (inactive/sedentary/active/very-active), smoking and alcohol use were self-reported. Linear regression modelling was used to determine associations of IC with components of sarcopenia and lifestyle factors.

Results: Median IC score=12 (range 4-14). In separate models, low-HGS (β= -2.178, se 0.547, p<0.001) and low-ALM/h^2 (β= -1.242, se 0.464, p=0.008) were negatively associated with IC scores. In a multivariable model, independent associations with IC included low-HGS (β= -1.379, se 0.463, p=0.003), low-ALM/h^2 (β= -1.180, se 0.373, p=0.002), age (β= -0.074, se 0.017, p<0.001), smoking (β= -1.318, se 0.494, p=0.008) and physical activity: with 'inactive' as reference, sedentary (β=2.305, se 0.434), active (β=2.676, se 0.419) and very-active (β=3.000, se 0.464) groups showed a dose-related association with IC (all p<0.001).

Conclusion: The association between components of sarcopenia and lower IC scores, independent of age and movement, suggest that further research should investigate the ICOPE framework as a screener for functional deterioration, psychological decline and energy imbalance, all of which contribute to sarcopenia.

OC21

INCREASED DIETARY FIBER INTAKE IS ASSOCIATED WITH BETTER GRIP STRENGTH AND PHYSICAL PERFORMANCE IN COMMUNITY-DWELLING OLDER ADULTS

L. Lapauw[1], N. Amini[1], L. Peeters[1], M. Derrien[2,3], J. Raes[2,3], E. Gielen[1,4], J. Dupont[1,4]

[1]KU Leuven, Department of Public Health and Primary Care, division of Gerontology and Geriatrics, Leuven , Belgium; [2]KU Leuven, Rega Institute, Department of Microbiology, Immunology and Transplantation, Laboratory of Molecular Bacteriology, Leuven , Belgium; [3]VIB-KU Leuven Center for Microbiology, Leuven, Belgium, Leuven, Belgium; [4]UZ Leuven, division of Geriatric Medicine, Leuven , Belgium

Objective: Poor habitual diet may contribute to sarcopenia via gut microbiota–mediated inflammation, yet evidence in older adults is scarce. In this study we aimed to investigate associations of habitual dietary fiber and fatty acid intake with sarcopenia-defining parameters and with intestinal and systemic inflammation.

Methods: This retrospective, cross-sectional analysis included data from the Trial in Elderly with Musculoskeletal Problems due Underlying Sarcopenia-Faeces to Unravel the Gut and Inflammation Translationally (TEMPUS-FUGIT, NCT05008770) and Exercise and Nutrition for Healthy AgeiNg (ENHANce, NCT03649698) studies. Dietary intake was assessed through four-day food records in community-dwelling persons aged ≥65 years. Eighty-four participants with probable, confirmed or severe sarcopenia as per European Working Group on Sarcopenia in Older Persons 2 (EWGSOP2) and 100 controls without sarcopenia were included. Muscle mass and function were evaluated using appendicular lean mass (ALM), handgrip strength (HGS), the 5-time Chair Stand Test (CST), Short Physical Performance Battery (SPPB), and gait speed. Assessed inflammatory markers included interleukins (IL)-4, IL-6 and IL-10, Tumor Necrosis Factor (TNF)-α, InterFeroN (IFN)-γ, White Blood Cells (WBC), high sensitivity C reactive protein (hs-CRP), Erythrocyte Sedimentation Rate (ESR), albumin and fecal calprotectin (fCPT). Group comparisons and correlations were multiple-testing adjusted and associations were adjusted for age, body mass index, sex, mean steps, nutritional status and energy intake in linear regression models.

Results: In the entire cohort, HGS associated positively with protein (β=0.264; 95% Confidence Interval (CI) [0.013;0.515]) and total fiber (β=0.236; 95% CI [0.077;0.395]) intake. The total SPPB score associated with total (β=0.113; 95% CI [0.006;0.220]) and soluble fiber (β=0.093; 95% CI [0.013;0.172]) intake. PUFA (β= -0.133; 95% CI [-0.244;-0.022]) and omega-6 (β= -0.115; 95% CI [-0.214;-0.016]) associated negatively with WBC counts. Among persons with any stage of sarcopenia, fCPT correlated inversely with total (ρ= -0.450) and soluble fiber (ρ= -0.436). Protein, DocosaHexanoic Acid (DHA) and soluble fiber declined with increasing sarcopenia severity, whereas omega-6/omega-3 ratio increased. All reported results were significant (p<0.05).

Conclusions: These results point to fiber-rich eating patterns, emphasizing total and soluble fiber sources (highly present in legumes, beans, oats, and fruits), as meaningful for maintaining muscle strength, function, and intestinal inflammatory status for age-related health.

Disclosures: all authors have nothing to disclose.

OC22

EFFECT OF DALCROZE EURHYTHMICS EXERCISE ON MUSCLE, PHYSICAL AND COGNITIVE FUNCTION, AND FALLS IN SARCOPENIC OLDER ADULTS: THE SARCARE RANDOMIZED CONTROLLED TRIAL

A. Trombetti[1], A. Tahar[2], F. Herrmann[2], C. Graf[2], T. Chevalley[3], R. Rizzoli[3], M. Hars[1]

[1]Division of Bone Diseases & Division of Geriatrics and Rehabilitation, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland; [2]Division of Geriatrics and Rehabilitation, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland; [3]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland

Objectives Given the growing evidence pointing towards the key role of the central nervous system in sarcopenia, it can be hypothesized that specific interventions influencing this system may also exert a significant effect on muscle function in sarcopenic elders. Dalcroze Eurhythmics (DE) exercise has been shown to increase physical performances and reduce falls in older adults at high risk for falls, and to modify CNS activity. The SARCARE trial, a proof-of-concept study, was mainly designed to determine i) the effectiveness of a DE exercise intervention in improving muscle, physical and cognitive function and reducing falls in sarcopenic older adults, and ii) whether exercise-related benefits are associated/mediated with changes at central level.

Material and Methods We conducted a single-centre, single-blind, two-arm, randomized controlled trial, in which 196 community-dwelling adults ≥65 years (mean age, 75.2 years; 89% women) with low lean mass and low physical performance were randomized (1:1) to i) a DE exercise group (2x/week supervised group-based) or ii) a CONtrol group (no exercise) for 12 months, and assessed at baseline, 6- and 12-month. Both groups also received regular educational lectures. The primary outcome was change in Short Physical Performance Battery (SPPB) score at 12 months. Secondary outcomes included, among others, changes in muscle strength and mass (assessed by DXA), cognition, and falls.

Results At 12 months, physical function improved in the DE group compared to the CON group (group*time interaction for SPPB score: 1.16, 95%CI 0.76 to 1.56; p<0.001). Significant improvements were also found in the DE group on muscle strength (5x chair stand time & handgrip strength, p<0.005 for both) compared to the CON group, while no effect was found on muscle mass (ALM/height^2, p=0.947). Also, the DE group improved on a variety of cognitive/executive function outcomes compared to CON group (e.g., Trail Making Test-Part B, p<0.001). The adjusted hazard ratio for falls was 0.56 (95%CI 0.33 to 0.95; p=0.030) in favor of the DE group.

Conclusions A 12-month DE exercise program was effective in improving muscle, physical and cognitive function, and reducing falls in sarcopenic older adults. Further analyses will help clarify the mechanisms underlying the muscular benefits of DE training.

OC23

IDENTIFICATION OF FACTORS ASSOCIATED WITH NON-RESPONSE TO A MULTICOMPONENT INTERVENTION IN OLDER ADULTS WITH PHYSICAL FRAILTY AND SARCOPENIA

R. Calvani[1], E. Marzetti[1], A. E. Nuzzi[1], A. Álvarez-Bustos[2], H. J. Coelho Júnior[3], S. Cacciatore[4], M. Tosato[3], F. Landi[1]

[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]Department of Health, Universidad Villanueva,, Madrid, Spain; [3]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [4]University of Florida, Gainesville, United States

Objective(s) To identify baseline characteristics associated with incident mobility disability among older adults with physical frailty and sarcopenia showing high adherence to a multicomponent intervention.

Materials and Methods This is a secondary analysis of the SPRINTT randomized controlled trial, which evaluated a multicomponent intervention based on physical activity and nutritional counselling to prevent mobility disability in community-dwelling older adults with physical frailty and sarcopenia. The present analysis focused on participants allocated to the intervention arm who showed high adherence to physical activity, defined according to American College of Sports Medicine recommendations as attending ≥2–3 sessions per week. Incident mobility disability was operationalised as inability to complete the 400-m walk test in <15 minutes during follow-up. Logistic regression, Kaplan–Meier and Cox proportional hazards models were used to identify predictors of incident mobility disability. Models were progressively adjusted for potential confounders. Additional analyses explored the association between baseline walking performance and incident mobility disability using different modelling strategies, including alternative operationalisations of walking performance. Sensitivity analyses were conducted to assess the robustness of the findings under different analytical assumptions.

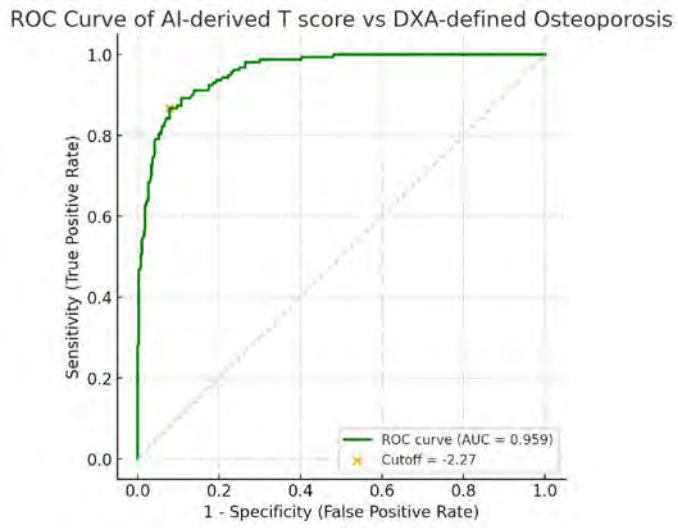
Results Among 352 participants with high adherence (mean age 78.7±5.5 years, 72.7% women), 110 (31.3%) developed incident mobility disability. At baseline, those who developed disability were older and had significantly slower 400-m walk time (569±153 vs 479±119 s, p<0.001). In logistic regression, baseline walk time was independently associated with mobility disability (OR per minute increase: 1.27, 95% CI 1.13–1.42), together with age. Antiepileptic and antithrombotic drug use were also associated with higher risk, but their inclusion did not affect model discrimination. In survival analyses, each additional minute of baseline walk time increased the hazard of disability by 20% (HR 1.20, 95% CI 1.12–1.29). Using a 480-second (or 8-minute) cut-off, participants with slower baseline walk had a more than two-fold higher risk compared with faster walkers (HR 2.47, 95% CI 1.66–3.66). Dose–response analyses across quartiles suggested a near-linear relationship between baseline walk time and disability risk. Results were consistent in sensitivity analyses and across different outcome adjudication strategies.

Conclusion(s) Among older adults with physical frailty and sarcopenia showing high adherence to a multicomponent intervention, baseline 400-m walk time is a strong and independent predictor of non-response. These findings suggest that functional severity at baseline may limit the effectiveness of lifestyle interventions, highlighting the need for personalised or intensified strategies in slower walkers.

OC24

CAN AI-DERIVED BMD FROM ROUTINE RADIOGRAPHS PREDICT FRACTURE RISK? A 6-YEAR FOLLOW-UP STUDY

J.-Y. Hsu[1], S.-H. Fu[2], T.-H. Tseng[3], C.-C. Hung[2], P.-C. Tsao[4], G. H. Chang[1], C.-Y. Wang[5]



[1]Program for Precision Health and Intelligent Medicine, Graduate School of Advanced Technology, National Taiwan University, Taipei City, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei City, Taiwan; [4]Department of Medical Imaging, National Taiwan University Hospital Yunlin Branch, Douliu, Taiwan; [5]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

Objective(s) To determine whether AI-derived bone mineral density (BMD) from routine spine radiographs can predict real-world fracture events, and to validate the accuracy of AI-based BMD estimation and its diagnostic performance for osteoporosis.

Material and Methods Adults aged ≥20 years with paired lumbar DXA and spine radiographs (lumbosacral or kidney-ureter-bladder) within 6 months were retrospectively analyzed from a tertiary medical centre in Taiwan (2014-2024). A commercially cleared AI algorithm (DeepXray Spina) estimated lumbar BMD from radiographs. Agreement between AI- and DXA-derived BMD was assessed using Pearson correlation, intraclass correlation coefficient (ICC), and Bland-Altman analysis. Diagnostic accuracy for osteoporosis (T-score ≤−2.5) was evaluated by ROC analysis and Cohen's κ. Fracture prediction for vertebral, hip, and all-site fractures was assessed using ROC analysis with DeLong's test comparing AI and DXA performance.

Results Among 540 participants (73.9% female; mean age 57.0 years), mean follow-up was 6.4 years. AI- and DXA-derived BMD showed excellent agreement (r=0.943; ICC=0.934). For osteoporosis diagnosis, AI-derived T-scores achieved AUC of 0.959 with κ=0.74 and 90% accuracy. During follow-up, 57 vertebral fractures, 13 hip fractures, and 100 all-site fractures occurred. AI-derived BMD predicted vertebral fractures (AUC 0.704 vs 0.678, p=0.086) and hip fractures (AUC 0.716 vs 0.678, p=0.078) comparably to DXA. For all-site fractures, AI demonstrated significantly better prediction (AUC 0.699 vs 0.677, p=0.042). Lower AI-derived BMD was significantly associated with higher fracture risk (OR 1.74 per 0.1 g/cm² decrease for vertebral fractures).

Conclusion(s) AI-derived BMD from routine radiographs demonstrates excellent agreement with DXA and predicts fracture risk comparably or even superiorly to DXA over long-term follow-up. This approach enables opportunistic identification of high-risk individuals, supporting population-level osteoporosis screening where DXA is unavailable.

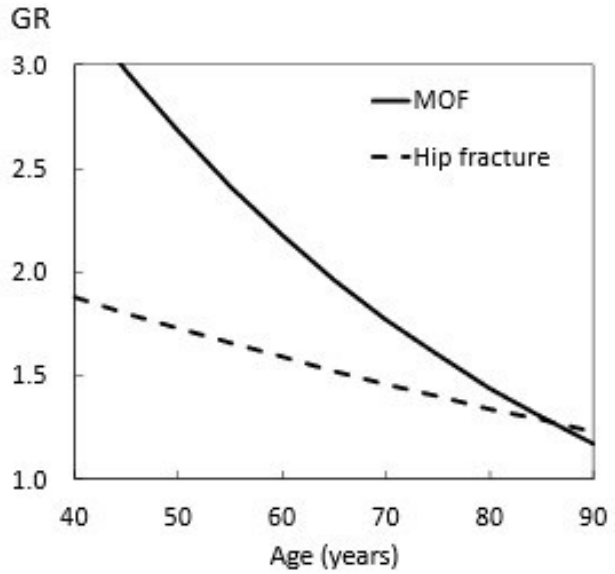
OC25

FOREARM BMD IS A FRAX INDEPENDENT PREDICTOR OF FRACTURE RISK

E. McCloskey[1], H. Johansson[2], N. Harvey[3], M. Lorentzon[4], W. Leslie[5], J. Kanis[2]

[1]Mellanby Centre for Musculoskeletal Research, Division of Clinical Medicine, School of Medicine & Population Health, University of Sheffield,, Sheffield, United Kingdom; [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [3]NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [4]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; [5]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objectives: The aim of this study was to quantify the relationship between forearm BMD, FRAX probabilities and fracture risk, and to examine the effect of age, sex, time since measurement and BMD value on fracture risk.



Materials and methods: 35121 men and women from 11 predominately population-based cohorts were followed for an average of 11.1 years and a total of 388,654 person-years. The association between forearm BMD, FRAX probabilities (calculated without femoral neck BMD), and the risk of fracture was examined using an extension of the Poisson regression model in each cohort by sex and expressed as the gradient of risk (GR; hazard ratio per 1 SD decrease in BMD). The different studies were merged using weighted coefficients.

Results: The GR of forearm BMD for major osteoporotic fracture was 1.41 (95% confidence interval [CI] 1.31-1.51) when adjusted for age and time since baseline and was similar in men and women (p> 0.20). GRs decreased significantly with age (Figure). When additionally adjusted for FRAX 10-year probability of major osteoporotic fracture, forearm BMD remained a significant, independent predictor for fracture (GR = 1.34, 95% CI 1.26-1.44). A similar GR was noted for hip fracture (GR=1.48; 95% CI 1.35-1.62) that also persisted after adjustment for FRAX (GR=1.41;

95% CI 1.31-1.51). Adjustments to FRAX probabilities based on forearm BMD varied by age and Z-score.

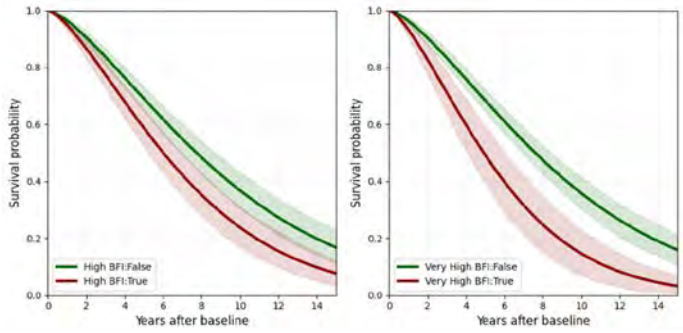
Conclusion: Forearm BMD is a risk factor for fracture that is independent of FRAX. Its validation on an international basis could enable its use in case finding with FRAX.

Figure. Gradient of risk (GR) of forearm BMD for hip fracture or MOF FRAX probabilities according to age

OC26

PREDICTION OF INCIDENT FRACTURES USING THE AI-BASED TBS REVEAL BONE FRAGILITY INDEX: A BAYESIAN SURVIVAL ANALYSIS

G. Gatineau[1,2], P. Eghbalishamsabadi[2], M. De Gruttola[2], K. Hind[2,3], M. Davies[2], A. Walstra[2], D. Krueger[4], N. Binkley[4], O. Suhail Alsaed[5], S. Alemadi[5], D. Hans[1,2]



[1]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland; [2]Medimaps group SA, Geneva, Switzerland; [3]Faculty of Health & Medicine, Lancaster University, Lancaster, United Kingdom; [4]School of Medicine and Public Health, University of Wisconsin, Madison, United States; [5]Hamad Medical Corporation, Doha, Qatar

Objectives: AI tools for osteoporosis assessment have potential for estimating bone mineral density (BMD) from radiographs; however, typically quantify BMD alone and do not account for microarchitecture. To date, these tools have not demonstrated performance for predicting incident fractures. TBS Reveal™ is an AI-driven solution addressing this gap by deriving a Bone Fragility Index (BFI) from X-ray images through integration of trabecular bone score (TBS) and BMD-related information. This study evaluated the ability of TBS Reveal™ to predict fracture-free survival and the timing of major osteoporotic fractures (MOF).

Materials and Methods: 338 women (mean±SD age 68.3±9.4 years) received baseline spine X-ray imaging with prospective MOF follow-up. TBS Reveal™ was applied to derive the BFI. High BFI was defined as osteoporosis or degraded TBS with osteopenia, and Very High BFI as degraded TBS with osteoporosis. Fracture-free survival was defined from baseline imaging to first MOF. Associations between BFI category and fracture risk were evaluated using a Bayesian Weibull proportional hazards model, comparing High BFI versus all others and Very High BFI versus all others. Five and ten-year fracture probabilities were estimated at the cohort mean age to isolate the effect of bone fragility classification.

Results: 157 participants sustained an incident MOF, with a median time to first fracture of 7.7 years (95%CI: 6.8–8.5). At baseline, 102 participants were classified as High BFI and 44 as Very High BFI. BFI was strongly associated with incident fracture risk, particularly within 5 years. Compared with all other participants, those classified as High BFI had a 10.3% higher 5-year fracture probability (95%CI: 1.2–19.5), increasing to 12.9% at 10 years (95%CI: 1.5–23.6). The Very High BFI group showed a more pronounced effect, with a 19.2% higher 5-year fracture probability (95%CI: 6.3–31.8) and a 21.0% higher probability at 10 years (95%CI: 7.9–31.2). Fracture-free survival curves separated early and remained distinct across BFI categories.

Conclusions: The TBS Reveal™ BFI predicted incident fracture timing, with robust discrimination of short-term fracture risk. By identifying accelerated time-to-fracture profiles from a single X-ray, TBS Reveal™ provides clinically actionable stratification of short and long-term fracture risk, supporting earlier, more targeted fracture prevention strategies.

OC27

3D-SHAPER DIFFERENTIATION OF CORTICAL AND TRABECULAR BONE DESCRIBES FRACTURE STATUS IN PATIENTS WITH KIDNEY DISEASE

H. El-Bilbeisi[1], T. Kotzur[1], M. A. Aponte[1], M. Hussain[1], M. Balogun[1], M. Mohseni[1], L. Humbert[2], M. Bracco[2], T. Nickolas[1]

[1]Washington University School of Medicine, St. Louis, United States; [2]3D SHAPER, Barcelona, Spain

Both cortical and trabecular bone are impaired in patients with chronic kidney disease (CKD) and contribute to increased fracture risk. However, the clinical standard to classify risk, areal bone mineral density (aBMD) by dual energy X-ray absorptiometry (DXA), is a 2-dimensional (D) measure and cannot assess differential contributions of cortical and trabecular bone to fragility. 3D-SHAPER is a novel technological tool applied to DXA imaging that permits 3D analysis of the hip DXA image. 3D models capture femoral geometry, density distribution, cortical and trabecular density. We performed 3D-SHAPER and DXA in 97 patients with (n=31)

and without (n=66) fracture. 3D-SHAPER and DXA data were analyzed as Z-scores to account for age and sex interactions. The total cohort mean age (IQR) was 66.7 (60.0-73.2) years, 53% were females, and 36%, 38% and 27% had CKD Stage 1-3, 4-5 and 5D respectively. CKD duration was 9.2 years. There were no between-group differences in age, gender or CKD stage or duration. Subjects with fracture had lower weight and BMI (74.5 vs 81.3 kg, p<0.05; and 27.6 vs 29.5 kg/m^2, p=0.04, respectively). 3D-SHAPER cortical and trabecular measures were highly and directly correlated with total hip and femoral neck aBMD (r 0.80-0.87, p<0.001) but moderately and directly correlated with spine and forearm aBMD (r 0.41-0.58, p<0.001). In univariate analyses, measures from 3D-SHAPER and DXA discriminated fracture status (table), but trabecular volumetric BMD had highest discrimination. In backward selection multivariate analyses including cortical surface BMD (model 1) and trabecular volumetric BMD (model 2) and aBMD at the forearm and spine, only 3D-SHAPER parameters were selected as the discrimination metric. In conclusion, 3D-SHAPER and DXA measures discriminated fracture status, with superior performance demonstrated by 3D assessment of the individual bone compartments to fragility. Larger and prospective studies are needed to validate these findings.

Z-scores	Fracture (mean±SD)	No fracture (mean±SD)	OR (95%CI)	AUC (95%CI)
3D-SHAPER Measures				
Trabecular volumetric BMD	-0.597 ± 1.286	0.305 ± 1.266	1.83(1.22-2.73)	0.70(0.58-0.81)
Cortical surface BMD	-0.760 ± 1.442	0.184 ± 1.398	1.59(1.14-2.22)	0.66(0.54-0.78)
DXA Measures				
Lumbar Spine	0.311 ± 1.880	1.183 ± 1.810	1.32(1.02-1.75)	0.63(0.51-0.76)
Total Hip	-0.388 ± 1.301	0.224 ± 1.063	1.60(1.08-2.37)	0.65(0.53-0.77)

PERFORMANCE OF NOGG GUIDELINES BASED ON FRAX PRIOR TO DXA VS FRAX CALCULATED USING A FEMORAL NECK ESTIMATE FROM AN OPPORTUNISTIC SCREEN OF LOW BONE DENSITY FROM STANDARD X-RAY

C. A. Syme[1], M. D. Cicero[1,2,3], M. Lopes[1], A. Bilbily[1,4]

[1]16 Bit Inc., Toronto, Canada; [2]True North Imaging, Toronto, Canada; [3]Department of Surgery, McMaster University, Hamilton, Canada; [4]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada

Objective: To assess the potential of a femoral neck (FN) T-Score estimated from an opportunistic screen of low bone density from standard x-rays (Rho) to improve NOGG risk categorization when used as an input to FRAX.

Material and Methods: In a retrospective dataset of consecutive patients with a Rho-eligible x-ray, DXA and FRAX inputs available, we calculated FRAX MOF score with no T-Score (FRAX-NoT), Rho-estimated FN T (FRAX-Rho), and a DXA FN T (FRAX-DXA). We classified patients in UK NOGG risk categories (low, intermediate, high) and as eligible for pharmacotherapy based on NOGG treatment guidelines (NOGG-RX; i.e., FRAX-DXA > NOGG intervention threshold).

Results: In 1,199 patients (74% female; 50-93 years of age; 56% low bone mass [lowest DXA T-Score > -2.5 and < -1] and 17% osteoporosis), agreement between risk category using FRAX-Rho and FRAX-DXA (Cohen's weighted κ=0.71 [0.68-0.75]) was significantly greater than agreement using FRAX-NoT and FRAX-DXA (0.60 [0.56-0.64]). Had patients been referred for DXA based on FRAX-Rho vs FRAX-NoT exceeding the lower assessment threshold, then 144/746 (19%) vs 140/633 (24%) of referred patients would qualify for NOGG-RX (p=0.22). FRAX-Rho would have referred a net of 113 more patients, but 91 of them would have had elevated fracture risk based on FRAX-DXA. Referral based on FRAX-Rho would not have missed any patients eligible for NOGG-RX while referral based on FRAX-NoT would have missed 4 patients eligible for NOGG-RX. Had patients been assigned high or very high risk, which qualifies for treatment initiation before DXA, based on FRAX-Rho vs FRAX-NoT, 96/113 (85%) vs 76/111 (68%; p=0.006) would truly be eligible for NOGG-RX.

Conclusions: DXA scans often have long waiting lists, and in some cases may not be available. A Rho-estimated FN T-Score has the potential to improve a FRAX-NoT estimate when DXA is not available, as it has significantly greater agreement with FRAX-DXA. It would correctly identify more patients eligible for therapy and would reduce the number of inappropriately treated prior to DXA.

Disclosures: The authors are/were employees of 16 Bit. MC and AB are inventors on a patent for the underlying technology, assigned to 16 Bit.

OC29

SUPERIOR FRAGILITY FRACTURE DISCRIMINATION BY CORTICAL ULTRASOUND SPECTROSCOPY COMPARED WITH BONE MINERAL DENSITY IN WOMEN AND MEN

G. Armbrecht[1], E. Wiebe[2], K. Raum[3]

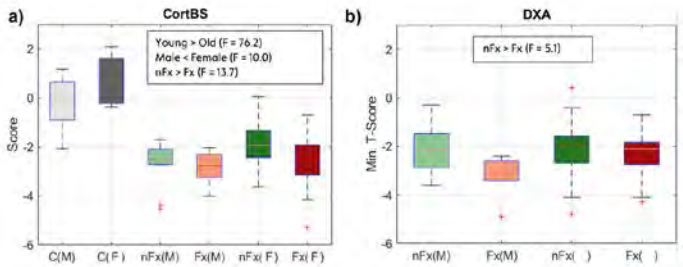
[1]Charité Universitätsmedizin Berlin, Department of Radiology, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Department of Rheumatology, Berlin, Germany; [3]Charité Universitätsmedizin Berlin, Center for Biomedicine, Berlin, Germany

Objectives:

Cortical ultrasound spectroscopy (CortBS) is an emerging, non-ionizing imaging modality that quantifies viscoelastic material properties and the distribution of intracortical pore sizes in the antero-medial region of the tibia midshaft. An initial investigation in postmenopausal women with reduced bone mineral density demonstrated superior fracture discrimination of CortBS compared with the current reference standard, dual-energy X-ray absorptiometry (DXA). The present study aims to assess the fracture discrimination performance of CortBS in both male and female patients as well as in young, healthy volunteers, and to directly compare its performance with DXA.

Material and Methods:

This cross-sectional study (DRKS00025849, EA4/068/19) included 144



women (among them 55 postmenopausal women from a prior study [1]) and 33 men, with an age range of 30–86 years (DXA performed in participants older than 56 years). DXA measurements were obtained at the lumbar spine and both proximal femora. CortBS assessments were conducted at the anteromedial tibial surface using a SonixTOUCH device equipped with dedicated custom software. Multivariate analysis of variance was applied to examine the effects of sex, age, and anthropometric (AP) parameters (height, weight, body mass index) on both CortBS and DXA outcomes. Discrimination performance for vertebral, non-vertebral, and any fragility fractures was evaluated using partial least squares (PLS) discriminant analysis with cross-validation, with and without inclusion of sex, age, and AP variables.

Results:

DXA T-scores were influenced by body weight and BMI and were significantly lower in individuals with non-vertebral fractures (F = 5.1). The CortBS-derived fracture risk score decreased significantly with age (F = 76.2), was significantly lower male than in female (F = 10.0) and, after adjusting for age and sex, lower in patients with fractures than in those without (F = 13.7). Across all fracture categories, CortBS demonstrated superior discrimination compared with DXA ($0.60 \leq AUC_{DXA} \leq 0.63$; $0.68 \leq AUC_{CortBS} \leq 0.74$).

Conclusions:

CortBS exhibits the age- and gender associated fracture risk and has a superior fracture discrimination performance than DXA.

OC30

INFRAPATELLAR FAT PAD MORPHOLOGY AND SIGNAL PREDICTS KNEE REPLACEMENT RISK IN OSTEOARTHRITIS: AN 8-YEAR MRI CASE-CONTROL STUDY

J.-P. Pelletier[1], P. Paiement[1], M. Dorais[2], J.-P. Raynauld[1], J. Martel-Pelletier[1]

[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada; [2]StatSciences Inc., Notre-Dame-de-l'Île-Perrot, Canada

Objective. This exploratory nested case-control study investigated whether infrapatellar fat pad (IPFP) morphology and signal intensity in knee osteoarthritis (OA) predict knee replacement (KR), using clinically meaningful thresholds of change.

Methods. Participants were drawn from the Osteoarthritis Initiative (OAI) progression cohort. Cases (KR, n=163) were matched 1:4 to controls (n=643) based on age, gender, body mass index, and follow-up duration. IPFP global, hyperintense, and hypointense signal intensity volumes and areas were quantified by MRI. Associations with KR were analyzed using adjusted conditional logistic regression, accounting for analgesic use, race, WOMAC pain, medial bone marrow lesions (BML), Kellgren-Lawrence grade, and new medial meniscal extrusion at KR index date. Analyses were conducted for values above and below the cohort median and further stratified by gender.

Results. At inclusion, cases and controls were generally balanced, except cases that reported greater pain (WOMAC, $p \leq 0.001$), higher analgesic use ($p \leq 0.001$), narrower joint space width (nJSW), and reduced cartilage volume, larger effusion, and more meniscal extrusion (analyzed by MRI) (all $p \leq 0.002$). Men showed larger IPFP volumes and hyperintense areas ($p \leq 0.001$). Median time to KR was ≈4.5 years. Over follow-up, cases exhibited sharper progression of pain, nJSW, medial cartilage loss, BML, and effusion (all $p \leq 0.03$), alongside increased IPFP hyperintense volume ($p=0.040$). Predictive analyses revealed that smaller (<median) hypointense areas at inclusion increased KR risk (overall OR=2.43, $p=0.049$; women OR=5.07, $p=0.034$). At the index date, larger (≥median) hyperintense IPFP volume and area predicted overall (OR=2.36, $p=0.048$; OR=2.69, $p=0.010$, respectively) and women (OR=2.89, $p=0.046$; OR=1.79, $p=0.039$) KR. Inverse associations were observed, with values ≥median at inclusion or <median at the index date linked to decreased KR risk.

Conclusion. IPFP morphology and hyperintense signal intensity are robust predictors of KR risk in OA, with directionality depending on threshold values. These associations persist after adjustment for conventional confounders.

QUANTIFYING TREATMENT-RELATED INFLAMMATORY CHANGE IN KNEE OSTEOARTHRITIS USING NORMALIZED MRI INFLAMMATION VOLUME (NORMI)

O. Kubassova[1], A. Singareddy[1], M. Clark[1], R. Hagoug[1], D. Skerrett[2]

[1]Image Analysis Group, London, United Kingdom; [2]Paradigm Biopharmaceuticals Ltd, Melbourne, Australia

OBJECTIVE

To apply a normalized MRI-based inflammation metric (normalized MRI inflammation volume; NORMI) within a multimodal osteoarthritis imaging framework to quantify joint-level inflammatory burden and to distinguish imaging-defined responders and non-responders in participants with knee osteoarthritis (OA) treated with injectable pentosan polysulfate sodium (iPPS, bene pharmaChem GmBH) or placebo.

METHODS

This exploratory Phase 2, randomized, double-blind, placebo-controlled study (anzctr.org.au identifier: ACTRN12621000136808) enrolled 61 participants with moderate to severe knee OA (Kellgren-Lawrence grade 2–4) and an inadequate response to conservative therapy. Participants randomized 1:1:1 to twice-weekly iPPS, once-weekly iPPS, or placebo for 6 weeks, with follow-up imaging at Day 168.

Post-gadolinium 3D knee MRI scans were analyzed to quantify synovial and bone marrow lesion (BME) volumes using a previously described quantitative computer-aided methods (Boesen et al., 2021). A blinded

radiology reader used DYNAMIKA (Image Analysis Group, London, UK) to place a 1 cm muscle region of interest (ROI) at baseline and Day 168, derive a reference signal, and identify enhancing voxels in synovium and bone marrow exceeding a two-standard deviation threshold. Rough ROIs were then drawn around synovium and BME on all slices, and total synovial inflammation and BME volumes were automatically computed as the number of voxels above this enhancement threshold, yielding continuous measures of inflammatory change (see Figure 1).

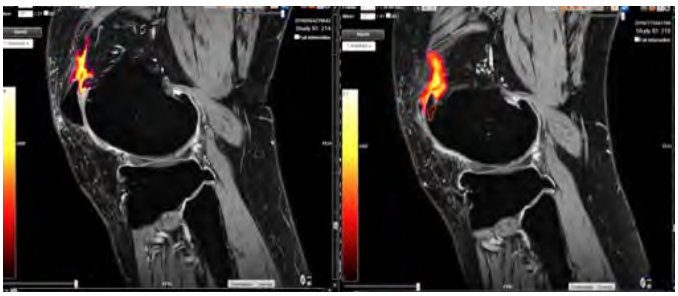

Figure 1. Normalized MRI inflammation volume (NORMI): Baseline and post-treatment knee OA maps showing clear reduction in synovial activity.

RESULTS

MRI analysis was focused on quantification of changes in BME and synovitis. An 18% reduction of overall quantitative volume of BME was observed in the iPPS twice-weekly group, whereas placebo participants saw a 2% overall increase in BME. BME in the femur decreased by 16.1% in the iPPS twice-weekly arm, whereas in the placebo arm and the iPPS once-weekly arm BME increased by 77.0% and 4.1%, respectively. BME in the tibia and patella increased in all three arms. Synovitis, as measured by the volume of gadolinium-enhancing synovial tissue and fluid in the joint, increased in the placebo arm (4.6%) and the iPPS once-weekly arm (30.1%), but decreased slightly (1%) in the iPPS twice-weekly arm.

CONCLUSION

NORMI provides a quantitative, joint-size-independent MRI endpoint within a multimodal imaging framework for knee OA. This approach supports objective assessment of inflammatory disease activity and imaging-based responder stratification, with potential utility for endpoint development in disease-modifying osteoarthritis drug clinical trials.

FROM MODEL TO APPLICATION: METABOLOMIC-DRIVEN MACHINE LEARNING FOR PROGNOSIS OF KNEE STRUCTURAL OSTEOARTHRITIS PROGRESSION

A. Jamshidi[1], G. Zhai[2], M. Liu[2], W. Zhang[3], G. Jones[4], F. M. Cicuttini[5,6], J.-P. Pelletier[1], J. Martel-Pelletier[1]

[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada; [2]Human Genetics & Genomics, Division of Biomedical Sciences, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Canada; [3]School of Pharmaceutical Sciences, Jilin University, Changchun, China; [4]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; [5]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia; [6]Department of Rheumatology, Alfred Hospital, Melbourne, Australia

Objective. We aimed to develop and validate a metabolomic-driven machine learning (ML) prognostic model for structural progression in knee osteoarthritis (OA).

Methods. Baseline serum metabolomic data from two independent cohorts were analyzed: Tasmanian Older Adult Cohort (n=180) for model development and Licofelone trial (n=137) for validation. Participants were categorized by likelihood of knee structural progression using MRI and X-ray data. Four metabolomic scenarios were assessed: metabolites (104), plus ratios and inverse ratios (each 5,460), and all combined (10,816), alongside age, sex, and BMI. Profiling used high-throughput omics, with batch effects corrected. Feature selection combined variable clustering with elastic net regularization. Top features of each scenario were trained with five ML/DL models, and performance assessed by AUC, accuracy, sensitivity, and specificity, with 95% confidence intervals. Feature contributions were analyzed via SHapley Additive exPlanations (SHAP).

Results. The metabolomic-only scenario, including sex and age, yielded the best performance. After clustering, the top 10 features were used. An Artificial Neural Network with a domain-adversarial component outperformed other algorithms under domain shift. The final model, including six metabolites (SM (OH) C22:2, proline, citrulline, LysoPC a C18:0, glutamate, and C12-DC), plus sex and age, demonstrated excellent predictive performance (test: AUC 0.98[0.95,1.00], accuracy 0.89[0.84,0.94]; validation: AUC 0.89[0.83,0.95], accuracy 0.85[0.79,0.91]). SHAP ranked SM (OH) C22:2 highest, followed by proline, citrulline, sex, age, LysoPC a C18:0, glutamate, and C12-DC. SM (OH) C22:2 and glutamate were positively associated with progression, while others showed nonlinear effects, with intermediate values influencing predictions differently than extremes. Females had a slightly higher risk.

Conclusion. This validated, public GitHub-hosted metabolomic-driven DL framework introduces a novel approach for predicting knee OA structural progression. This framework advances precision OA management, enabling earlier interventions and effective therapeutic development.

TOWARDS OA PATIENTS ENDOTYPING : DEVELOPMENT OF AN LC-MS/MS METHOD FOR THE QUANTITATION OF JOINT-RELATED COLLAGENS FRAGMENTS

J. Demeuse[1], L. Kalut[1], A. Mackowiak[1], M. Piette[1], E. Grifnée[2], E. Cavalier[2]

[1]Laboratory of Clinical Chemistry, CIRM, ULiège, Liège, Belgium; [2]Department of Clinical Chemistry, University Hospital of Liège, Liège, Belgium

Objectives: This study aimed to develop a targeted LC–MS/MS method for the quantitation of a broad panel of plasma-derived fragments originating from joint-related collagens (types I, II, and III). The optimised method will subsequently be used to stratify osteoarthritis (OA) patients according to molecular endotypes using a clustering-based statistical

workflow, with the long-term goal of supporting personalised medicine approaches in OA.

Materials and methods: In silico multi-enzymatic digestions of collagens type I–III were performed, and MRM transitions were designed using Skyline. The transition list was implemented on a triple quadrupole mass spectrometer (TQ6500, Sciex) coupled to a UPLC system (Shimadzu). To validate the transitions, bone, cartilage, and synovial membrane tissues were digested using trypsin, chymotrypsin, and Glu-C, followed by purification and size exclusion chromatography fractionation. Samples were analysed by LC–MS/MS to confirm the detectability of collagen-derived peptides.

Results: Bone tissue analysis enabled the detection of 132 peptides from the α1 and α2 chains of type I collagen, corresponding to nearly 50% sequence coverage. Cartilage tissue analysis yielded 74 peptides from type II collagen, with a coverage of 48%, while synovial membrane analysis resulted in the detection of 55 peptides from type III collagen, corresponding to a coverage of 40%. Regions with lower coverage mainly corresponded to telopeptides, likely due to cross-linking and post-translational modifications.

Conclusion: The developed LC–MS/MS method enabled the detection of 261 peptides derived from joint-related collagens. From an initial set of 14,350 theoretical transitions, 950, 293, and 232 transitions were retained for collagens type I, II, and III, respectively. This validated transition panel provides a robust analytical foundation for adaptation to plasma samples and for the molecular stratification of OA patients, supporting future personalised medicine strategies.

INTRA-ARTICULAR POLYACRYLAMIDE HYDROGEL FOR KNEE OSTEOARTHRITIS: 1-YEAR RESULTS FROM THE LUNA OBSERVATIONAL STUDY

A. Migliore[1], E. Fockens[2], P. Peev[3], P. Massin[4], J. Beier[5], S. Maimen[6], P. Drees[7], T. Klonschinski[7], H. Henning[8]

[1]Ospedale San Pietro FBF, Rome, Italy; [2]AP-HM Hôpitaux Sud Sainte-Marguerite, Marseille, France; [3]London North West University Healthcare, NHS Trust, London, United Kingdom; [4]Clinique Saint Louis, Poissy, France; [5]Reumatologerne Beier & Morillon, Odense, Denmark; [6]Royal Cornwall Hospital, Truro, United Kingdom; [7]University Hospital Mainz, Mainz, Germany; [8]The Parker Institute, Bispebjerg & Frederiksberg Hospital, University of Copenhagen, Copenhagen, Denmark

Objectives 2.5% injectable polyacrylamide hydrogel (iPAAG) is a CE-marked synovial implant for symptomatic knee osteoarthritis (OA). The LUNA study (NCT05057559) evaluates the safety, tolerability, and efficacy of a single intra-articular (IA) injection of 2.5% PAAG in participants with moderate-to-severe knee OA in a prospective, observational, open-label study.

Materials & Methods This multicentre European study enrolled patients with clinically diagnosed knee OA according to the European instructions for use for 2.5% iPAAG. Participants received a single 6 mL IA injection of 2.5% PAAG and are being followed for 5 years. This abstract reports the 1-year interim results.

The primary endpoint was the incidence and nature of adverse events (AEs). Secondary endpoints included changes from baseline in WOMAC pain, stiffness, and physical function, as well as Patient Global Assessment (PGA). Outcomes were analysed using a mixed model for repeated measures (MMRM) with restricted maximum likelihood (REML) estimation.

Results A total of 199 participants (106 women; mean age 62.8 years) were enrolled, of whom 189 completed the 1-year follow-up.

Most AEs were mild and transient. The most frequently reported device-related AEs were injection site pain (n=9; events=10) and arthralgia (n=5; events=6). 6 serious AEs were reported (hip joint abscess, urinary tract infection, intussusception, post procedural discharge, laparotomy, haematoma in psoas muscle); none were assessed as related to 2.5% PAAG IA injection.

Clinically relevant and statistically significant improvements in WOMAC pain were observed at 1 year compared with baseline (−17.0; 95% CI −19.6 to −14.4). WOMAC stiffness, WOMAC physical function, and PGA showed similar clinically relevant and statistically significant improvements.

Conclusion The 1-year interim results demonstrate that a single IA injection of 2.5% PAAG is well tolerated in participants with knee OA, with no device-related serious AEs. Sustained improvements in pain and function over 12 months support its role as a well-tolerated, non-surgical treatment option for knee OA.

Hyaluronic acid (HA) is a linear polysaccharide which occurs naturally as a constituent of synovial fluid. The HA concentration in the joint decreases inexorably during the progression of knee osteoarthritis (OA) and so, for nearly five decades, HA has been trialled and used in the treatment of knee OA. International and domestic guidelines vary in the degree to which they recommend the use of intra-articular hyaluronic acid (IAHA) with some supporting and others discouraging its usage. There are strong data from clinical trials, meta-analyses and umbrella reviews to support the use of IAHA in the treatment of patients with knee OA, though not in patients with acute, active osteoarthritis experiencing a flare. The majority of the literature suggests that IAHA has a positive safety profile despite a few meta-analyses suggesting an increased risk of serious adverse effects. Further qualitative analysis is required in order to further explore these findings. IAHA has been combined with a number of additional agents, including mannitol, sorbitol, chondroitin sulphate, tranexamic acid, polynucleotides and hybrid IAHA formulations. These show variable performance beyond the baseline effect of their constituents. It is, of course, crucial to consider the patient preference when considering treatments for knee osteoarthritis. Specific to HA, considerations regarding needle gauge, volume of injection, number of injections and duration of action are paramount.

OC36

IS EFFUSION SYNOVITIS, ASSESSED QUANTITATIVELY BY MORPHOMETRY OR SEMI-QUANTITATIVELY BY EXPERT READING; RELATED TO OSTEOARTHRITIS PROGRESSION

F. Eckstein[1], K. Sheikhi Valashani[2], T. Winkler[3], J. Collins[4], F. Roemer[5], A. Guermazi[6], D. Hunter[7], W. Wirth[8]

[1]Paracelsus Medical University / Center of Anatomy & LBIAR & Chondrometrics GmbH, Salzburg, Austria; [2]Chondrometrics GmbH, Freilassing, Germany; [3]Berlin Institute of Health / Charite - Universitätsmedizin Berlin, Julius Wolff Institute, Berlin, Germany; [4]Brigham and Women's Hospital / Harvard Medical School, Boston, United States; [5]Radiology, Universitätsklinikum Erlangen & BICL, Nuremberg, Germany; [6]VA Boston Healthcare System & BICL, West Roxbury, United States; [7]Rheumatology / Royal North Shore Hospital & Kolling Institute of Medical Research, Sydney, Australia; [8]Chondrometrics GmbH & Paracelsus Medical University / Center of Anatomy & LBIAR, Salzburg, Austria

Objectives: To develop fully automated, MRI-based quantitative volumetry for effusion synovitis (qESV), and to assess its utility for predicting OA progression compared with expert semi-quantitative (sq) MOAKS ES readings. In the absence of contrast enhancement (CE), ES severity is considered a sensitive, albeit not specific, surrogate of joint inflammation.

Methods: Automated segmentation of peripatellar ES was performed by a convolutional neural networks (CNN) AI algorithm, trained on >100 semi-automated segmentations with visual inspection. This was based on axial reformatted DESS MRIs from the FNIH Biomarker Study of the Osteoarthritis Initiative: 194 displayed combined radiographic and pain progression (2-4 years); 200 showed neither type of progression. Cohen's d (d) served as a measure of effect size (progressors vs. non-progressors). For validation purposes, q measures were converted into ordinal (sq) CNN-ES scores; the resulting sqORs for progressor status were compared with expert sq ES MOAKS readings. We assumed a monotonic ordering of categories, and the sqORs to represent a one-category increase.

Results: The qESV displayed a *d* of 0.24 (progressor status) and a qOR of 1.24 (95% CI 1.01, 1.51). The sqORs were 1.45 (95% CI 1.08, 1.94) for CNN-derived ES vs. 1.11 (95% CI 0.86, 1.43) for expert MOAKS grades. Most progressor/non-progressor comparisons were statistically significant.

Conclusions: We here evaluate the prognostic performance of ES volumetry with respect to OA progression status. The study relied on fully automated segmentation of ES using CNNs using DESS MRI. qESV morphometry revealed that, after conversion to ordinal scores, the difference between progressors and non-progressors was at least as high as that observed with expert MOAKS sq readings. The results suggest that a CNN-based automated pipeline can provide a scalable, q biomarker of inflammation as a potential surrogate endpoint in clinical studies.

BURDEN OF IMMINENT SUBSEQUENT FRACTURES IN POST-MENOPAUSAL WOMEN ACROSS MULTIPLE EUROPEAN PRIMARY CARE DATABASES

E. H. Tan[1], X. Chen[1], T. Rathod-Mistry[1], G. Fabiano[1], A. Moayyeri[2], J. Warden[2], C. Reyes[3], K. Verhamme[4], R. Pinedo-Villanueva[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]UCB, Slough, United Kingdom; [3]Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain; [4]Erasmus University Medical Center, Rotterdam, Netherlands

Objective: This study leveraged a federated network of standardised primary care databases across six European countries with the aim of quantifying the incidence and cumulative risk of imminent subsequent fractures (SF) within two years of an initial fracture.

Material and methods: Using the Observational Medical Outcomes Partnership Common Data Model, we collected electronic medical records data from primary care databases in the UK (CPRD), France (LPD), Germany (IQVIA DA), Italy (LPD), the Netherlands (IPCI), and Spain (SIDIAP). The cohort study included women aged ≥50 years with an index fracture between April 2010 and March 2018 and were followed up to two years after each fracture. Incidence rates of new imminent SF and two-year cumulative incidence, accounting for death as a competing risk using the Fine and Gray model were calculated.

Results: Patient counts for each dataset were: Spain: 143,992; Germany: 101,586; UK: 43,553; Italy: 24,406; the Netherlands: 16,423; and France: 14,919; Incidence rates per 1,000 person-years of SF were highest in Italy at 320.8 (95% CI: 314.6-327.1) and lowest in the UK at 118.0 (115.5-120.6). Rates in remaining countries ranged from: 142.0 (140.6-143.4) in Spain to 202.2 (196.1-208.5) in France. A trend of increasing incidence rates based on the number of previous fractures was seen across countries (Table 1) except for Italy, which did have the highest mean age of 75 years. The cumulative incidence of patients experiencing 1st SF in the UK was 19%, Among these, 23% experienced a 2nd SF within the following 2 years. Comparable patterns were observed across countries as follows: Spain (23% and 34%), the Netherlands (25% and 35%), Germany (30% and 38%), and France (30% and 46%). Notably, only Italy showed a decrease but remained high with 45% and 40%.

Conclusions: Imminent SF imposes a significant and growing burden on healthcare systems across Europe. Each additional fracture compounds risk and resource utilisation, emphasizing the need for early intervention after the first fracture. Coordinated strategies to prevent recurrence are critical to reduce this escalating cycle of fragility fractures and their associated impact.

Table 1: Incidence rate of subsequent fractures by the number of subsequent fractures in 6 European countries

	Incidence rate per 1000 person-years (95% CI)
Italy	
1st SF	321.2 (315.0, 327.5)
2nd SF	282.7 (229.0, 345.2)
France	
1st SF	201.8 (195.7, 208.1)

EFFECT OF DENOSUMAB ON IMPLANT SURVIVAL FOLLOWING TOTAL HIP AND KNEE ARTHROPLASTY IN OSTEOARTHRITIS PATIENTS: A REGISTRY-BASED DATA LINKAGE STUDY

J. Ciaffi[1], B. Bordini[2], M. Cosentino[2], A. Di Martino[1], C. Faldini[1], G. Mazziotti[3], R. Caporali[4], F. Ursini[1]

[1]University of Bologna; IRCCS Rizzoli Orthopedic Institute, Bologna, Italy; [2]IRCCS Rizzoli Orthopedic Institute, Bologna, Italy; [3]Humanitas University; IRCCS Humanitas Research Hospital;, Rozzano-Milan, Italy; [4]University of Milan; ASST Gaetano Pini, Milan, Italy

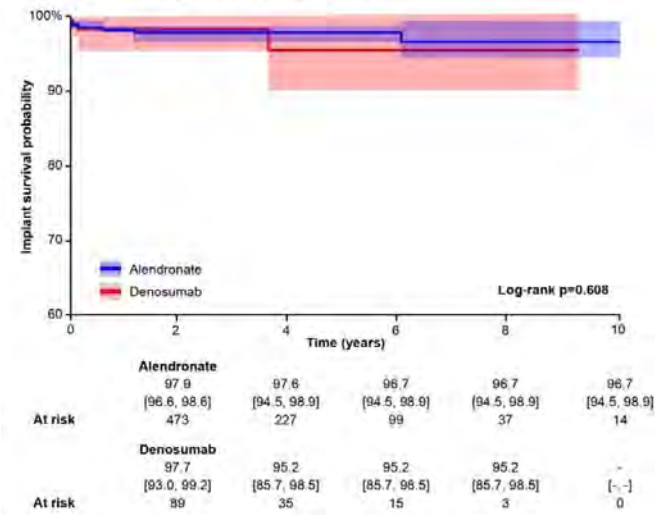
Objectives: Total hip arthroplasty (THA) and total knee arthroplasty (TKA) are now performed in millions of patients annually, yet over 60% of candidates have osteoporosis or osteopenia. Poor bone quality predisposes patients to periprosthetic fractures, implant migration, and aseptic loosening. Bisphosphonates provide a long-lasting antiresorptive effect, whereas denosumab suppresses osteoclast activity more rapidly but reversibly. It remains unclear whether these drugs differentially affect implant survival. The objective of our study is to compare the impact of perioperative denosumab versus alendronate treatment on implant survival following THA and TKA for OA, using real-world data.

Material and Methods: This retrospective cohort study used data from the Emilia-Romagna Registry of Orthopaedic Prosthetic Implants (RIPO). Patients undergoing primary TKA or THA for osteoarthritis between 2011 and 2023 were eligible. Perioperative exposure was defined as at least one dispensing of denosumab or alendronate in the 180 days before or after surgery. Follow-up continued until revision, death, emigration, or discontinuation of therapy. The outcome was first revision for any cause; analyses were stratified by joint and drug.

Results: The THA cohort comprised 129 denosumab and 933 alendronate users. Revision occurred in 4 denosumab (3.1%) and 21 alendronate patients (2.3%); Kaplan–Meier curves overlapped (Fig. 1), and the log-rank test was non-significant (p =0.608). In the TKA

cohort, 117 denosumab and 940 alendronate users were analysed. Here, 8 denosumab patients (6.8%) and 18 alendronate patients (1.9%) required revision, with a significant divergence in survival curves (Fig. 2; p <0.001). Revisions in denosumab users were mainly due to aseptic loosening of the tibial component, whereas only one case overall, in the TKA cohort, was related to infection, supporting a reassuring infective safety profile for denosumab. In both THA and TKA cohorts, denosumab and alendronate groups were comparable in terms of age, duration of drug exposure, and surgical characteristics.

Figure 1. Total hip arthroplasty cohort



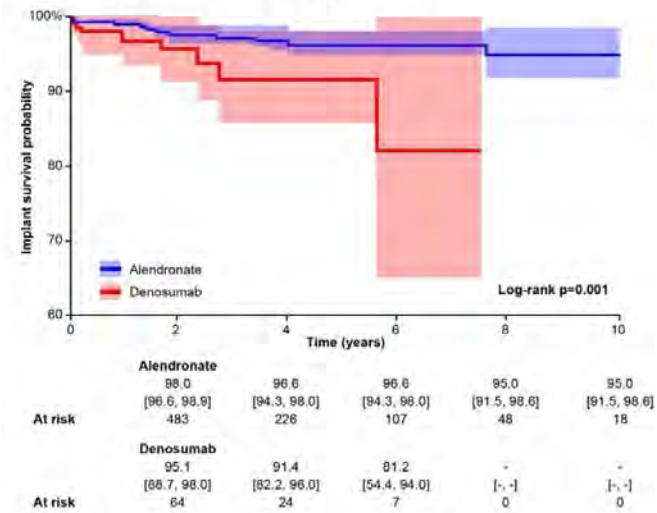


Figure 2. Total knee arthroplasty cohort

Conclusions: Perioperative denosumab exposure does not reduce implant survival after THA compared with alendronate but appears associated with a higher risk of revision after TKA. In the knee, the combination of systemic antiresorptive therapy and the biomechanical demands of the tibial component may compromise stability. Residual confounding by indication cannot be excluded, and further prospective studies are needed to confirm these findings and elucidate underlying mechanisms.

OC39

REDUCING PRE-OPERATIVE DELAY IN NECK OF FEMUR FRACTURE (NOFF) PATIENTS

J. R. Rosen[1], V. P. Suresh[2], S. B. Begum[2], V. G. Gupta[2], L. D. Dalton[2], L. B. Bellanti[2], F. E. Eales[2], L. F. Fraser[2], S. W. Wooldridge[2], G. M. Mccloskey[2], A. B. Baker[2], M. A. Arastu[2]

[1]University of Warwick, Coventry, United Kingdom; [2]University Hospital Coventry & Warwickshire, Coventry, United Kingdom

Introduction Neck of femur fractures are time-sensitive surgical emergencies. National Hip Fracture Database (NHFD) standards require surgery within 36 hours[1]. Mortality increases by 1.8% for every hour of delay beyond 36 hours[2]. To identify causes of pre-operative delay and track improvements from 2018–2025 using local data from a Major Trauma Hospital.

Methods & Materials Retrospective analysis of 3339 NOFF cases from a prospectively maintained database (2018-2025). Operative delay is defined as time to surgery >36 hours from arrival in an emergency department. Each delay was categorised as space, medical, imaging and unwell or unfit for surgery. Data collection was conducted using the NHFD and Microsoft Excel was used for data extraction.

Results Our unit has seen a 30% increase in NOFFs post covid compared to pre-pandemic levels. Yet the capacity to cater for such increase hasn't changed. 2024 saw a 55% increase in the annual average time to theatre for patients compared to pre-pandemic with the months May to December seeing an average time to theatre of 43 hours with the highest averages coming in June (49.92) followed by July and August which were 46 hours. We also found that the most common reason for patient delay to theatre was space which over the 5 years accounted for almost 80% of delays. Additionally, over the 5 years analysed 56 pts had periprosthetic fractures with an average delay of 68.8 hours.

Conclusion Real progress has been made in reducing clinically driven delays especially through anticoagulation protocols and earlier involvement from orthogeriatrics and anaesthetics. Despite this, overall compliance with the 36-hour target has declined. Theatre capacity has not kept pace with rising trauma demand, and delays are now often due to list overruns, resource constraints, or prioritisation of more complex cases.

Further Steps

- Early senior medical escalation at admission.
- Cultivating a work culture that prioritises NOFF care, ensuring theatre coordination and escalation mechanisms consistently support timely surgery.
- Incorporating Comprehensive Geriatric Assessment (CGA).

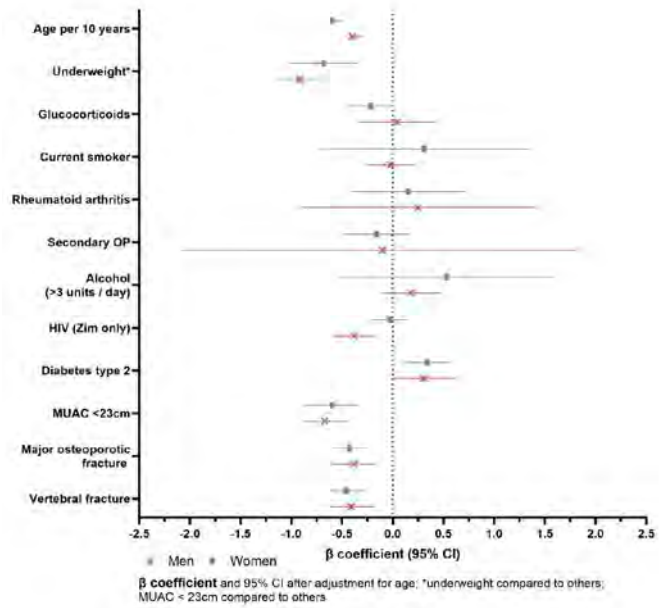
LIFESTYLE AND CLINICAL FACTORS ASSOCIATED WITH FEMORAL NECK BONE MINERAL DENSITY IN AFRICAN ADULTS: FINDINGS FROM THE FRACTURE-E3 STUDY

C. M. Pearse[1], L. S. Gates[1], A. J. Burton[2], M. K. Jallow[3], T. Manyanga[3], C. Grundy[4], N. J. Crabtree[5], E. M. Clark[6], H. Wilson[2], A. M. Manyara[2], T. Madanhire[2], B. Cassim[7], R. A. Ferrand[8], C. L. Gregson[2], K. A. Ward[1]



[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Global Health and Ageing Research Unit, University of Bristol, Bristol, United Kingdom; [3]MRC Unit The Gambia, Fajara, Gambia; [4]London School of Hygiene and Tropical Medicine, London, United Kingdom; [5]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [6]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom; [7]Department of Geriatrics, University of KwaZulu-Natal, Durban, South Africa; [8]Biomedical Research and Training Institute, Harare, Zimbabwe

Objective: To identify clinical, nutritional and lifestyle factors associated with femoral neck bone mineral density (FN-BMD) in women and men in Africa.

Methods: A population-based sample of adults aged ≥40 years, stratified by sex and age bands, were recruited in The Gambia and Zimbabwe. FN-BMD was measured using DXA, with vertebral fractures (VF) identified using Genant semiquantitative methods. Linear regression explored associations between demographic, nutritional, lifestyle and clinical risk factors and femoral neck T-scores, stratified by sex and adjusted for age (age-adjusted results shown in the figure). Factors assessed included underweight (BMI <18.5 kg/m²), low mid-upper arm circumference (MUAC <23 cm), HIV (Zimbabwe only), diabetes, glucocorticoid use, fracture history, rheumatoid arthritis (RA), secondary osteoporosis, smoking and alcohol intake.

Results: The study included 2181 participants (53% women), mean age 61.4 years; 5.8% were underweight and 6% had MUAC < 23 cm. After adjustment for age, markers of undernutrition, low BMI and low MUAC, were associated with lower FN-BMD in both sexes (women (w): β = −0.7 and β = −0.6; men (m): β = −0.9 and β = −0.7, respectively). Previous fractures were also associated with lower FN-BMD (w: VF β = −0.5, MOF β = −0.4; m: VF β = −0.4, MOF β = −0.4). HIV infection was independently associated with lower BMD in men only (β = −0.4), while type 2 diabetes was associated with lower BMD in women only (β = −0.3). Associations for smoking, alcohol intake and secondary osteoporosis seen in unadjusted models were attenuated after age adjustment. Several traditional osteoporosis risk factors, including glucocorticoid use and RA, showed no significant associations, potentially due to low prevalence (4.4% and 0.6%, respectively).

Conclusion: Undernutrition indicators (low BMI and MUAC <23 cm) and prior fractures (MOF and VF) were the strongest correlates of lower FN-BMD, with additional sex-specific associations for HIV (men) and diabetes (women). The absence of associations with several conventional risk factors suggests that in African settings, nutritional status and fracture history may be more informative. Given the limited access to DXA in many African countries, integrating simple anthropometric measures with fracture history may offer a more practical approach to identifying adults at increased fracture risk. Figure. Sex-specific associations between potential risk factors and FN-BMD, after adjustment for age

OC41

EXPLORING THE RELATIONSHIP BETWEEN BONE FORMATION AND RESORPTION CREATING BONE BALANCE INDEX FORMULAE IN ADULTS USING KIDNEY-INDEPENDENT BONE TURNOVER MARKERS

I. Trifonidi[1], D. Smout[2], A. Bouquegneau[3], E. Chronopoulos[4], H. S. Jørgensen[5], E. Cavalier[6], P. Everpoel[2], K. Makris[7]

Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece

Objective: Individual bone turnover markers inform on current whole-skeletal remodeling, but not the balance between bone formation and bone resorption. A calculated bone balance index (BBI) has been suggested to bridge this gap. To establish a BBI based on the relationship between non-kidney cleared biomarkers of bone formation (bone-specific alkaline phosphatase [BALP], intact pro-collagen type I N-terminal pro-peptide, [iPINP])) and bone resorption (tartrate resistant acid phosphatase isoform-5b [TRACP5b]) in a cohort of healthy individuals, and to utilize this BBI to explore net bone resorption relative to bone formation in an independent test cohort.

Materials and Methods: BBI was constructed leveraging data from 235 healthy volunteers (147 premenopausal women and 88 age-comparable men with BMD T-score >-1.0), presumed to be in a state of neutral bone remodeling. Equations were built using either iP1NP or BALP as the bone formation marker and TRACP5b and β-Crosslaps (β-CTX-I) as the bone resorption marker. We used linear regression to quantify the relationship between pairs of bone formation and resorption markers. BBI=0 indicates a neutral state, positive BBI-values indicate higher net formation relative to resorption, while negative indicate higher net resorption.

Results: The relationship between bone formation and bone resorption was sex-dependent for several biomarker-pairs. For BALP/TRACP5b, pair slopes differed between men (TRACP5b=1.967+0.042*BALP) and women (TRACP5b=1.081+0.104*BALP), supporting sex-specific equations. For iPINP/TRACP5b, (TRACP5b=1.259+0.020×iPINP) regression lines were statistically indistinguishable, suggesting that a single equation is acceptable for both sexes. For iPINP/β-CTX-I (men: β-CTX-I=116.749+4.921*iPINP, women: β-CTX-I=63.738+5.255*iPINP) and BALP/β-CTX-I (men: β-CTX-I=251.999+11.173*BALP, women: β-CTX-I=97.988+21.300*BALP) slopes were similar, but intercepts differed, favoring sex-specific equations. Once calculated by sex-appropriate equations, BBI was more positive in men compared to women across age-groups in all biomarker combinations. BBI was significantly higher in subjects with normal BMD compared to subjects with osteopenia or osteoporosis, when utilizing biomarker pairs consisting of TRACP5b as the resorption marker.

Conclusions: We provide a calculated BBI based on bone formation and resorption markers that are not affected by kidney function that could be utilized in the setting of kidney dysfunction. Future studies should explore the value of the BBI in predicting clinically relevant outcomes such as ongoing bone loss.

MANAGEMENT OF VERY HIGH FRACTURE RISK IN THE CONTEXT OF A LIFE-LONG OSTEOPOROSIS TREATMENT PLAN

M. McClung[1]

[1]Oregon Osteoporosis Center, Portland, United States

Osteoporosis is a chronic condition that requires long-term, often lifelong, management. Treatment needs vary depending on the stage of disease progression and a patient's fracture risk. Women at high risk for developing osteoporosis, as well as some individuals with low bone mass, may benefit from therapies that prevent further bone loss. Most patients whose bone mineral density (BMD) meets diagnostic criteria for osteoporosis are candidates for anti-remodeling medications such as bisphosphonates or denosumab.

A subset of patients, however, face very high or imminent fracture risk. This group includes those with recent or multiple fractures, very low BMD (T-score < −3.0), or several compounding risk factors. They require treatments that rapidly increase bone mass and strength and quickly reduce fracture risk. Evidence shows that osteoanabolic agents produce faster, larger gains in BMD and greater fracture-risk reduction than anti-remodeling drugs, making them the preferred initial therapy for these high-risk patients.

Because the anabolic effects of these agents diminish over time, patients typically transition to a bisphosphonate, denosumab, or occasionally another osteoanabolic drug to maintain the benefits achieved. A planned second course of osteoanabolic therapy is another possible strategy. This presentation will review these management options for patients at very high fracture risk following an initial course of osteoanabolic treatment.

PL2

BARRIERS AND FACILITATORS TO ORTHOGERIATRIC SERVICES

C. Gregson[1]

[1]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom

Orthogeriatric services are specialised models of care that integrate the principles of geriatric medicine into the orthopaedic management of older adults with fragility fractures, most services have evolved principally from the care of patients with hip fractures. These services are designed to address the complexity of older patients who often present with multiple comorbidities, frailty and high future falls and fracture risks. Services, usually led by orthogeriatricians, provide holistic, multidisciplinary care to address these needs and improve patient outcomes. Greater orthogeriatric input is generally associated with improved patient survival.

Multiple studies have considered barriers to orthogeriatric services, the principal barrier stems from lack of prioritisation of services within senior hospital management, and hence inadequate financial investment. Lack of senior clinical leadership, as well as understaffing or insufficient staffing skill mix within the multidisciplinary team pose further barriers.

Facilitators include having dedicated orthogeriatric wards, with skilled staff, who work well within a multidisciplinary team, supported by clinical governance structures, with a culture of transparent audit and data sharing within the whole team. Dedicated theatre lists for hip fractures, performed by senior anaesthetists, giving short anaesthetics, improve patient outcomes. Morbidity and mortality meetings held with surgeons, anaesthetists, orthogeriatricians and nurses offer multidisciplinary learning towards service improvement. National clinical audits in some countries have markedly improved orthogeriatric services, allowing an individual hospital to benchmark its performance against its neighbours. Good orthogeriatric services integrate with local fracture liaison services, and fall services, to ensure streamlined osteoporosis and fall risk management. A key to the delivery of complex care is effective communication and coordination within large multidisciplinary teams. Trauma coordinators can often assist in this endeavour. Standardised clinical documentation improves care delivered by diverse teams.

The REDUCE study in the UK has developed a wide range of service improvements tools, designed for use by hospital doctors and managers, to combat many of these barriers and improve orthogeriatric services.

PL3

HYPERGLYCAEMIA AND BONE HEALTH: DISEASE AND THERAPY

E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Both type 1 and type 2 diabetes mellitus have implications for skeletal health, both in terms of bone mineral density and fracture risk. Such associations are increasingly understood to be complex and involve both direct and indirect mechanisms. With the relentless increase in prevalence of overweight/obesity worldwide, type 2 diabetes presents an increasing healthcare burden globally. In this Plenary Presentation, the relationship between chronic hyperglycaemia and bone health will be explored across both type 1 and type 2 diabetes mellitus, comparing and contrasting mechanisms and associations across both diseases. The opposing relationships with bone mineral density will be highlighted, together with the apparent time-dependent nature of fracture risk with the onset of type 2 diabetes mellitus, and implications relating to altered material properties of bone in the context of hyperglycaemia. Appropriate terminology will be addressed, highlighting the distinction between such altered material properties and classical osteoporosis. Finally routes to appropriate clinical assessment will be appraised, such that skeletal health can be optimally assessed and managed in these superficially similar, but in reality often contrasting, chronic conditions.

PL4

IS THERE A ROLE FOR SEX HORMONES IN THE MANAGEMENT OF MUSCULOSKELETAL DISORDERS?

T. Simoncini[1]

[1]Head, Division of Gynecology and Obstetrics ; Department of Clinical and Reproductive Medicine, University of Pisa ; President, International Society of Gynecological Endocrinology, Pisa, Italy

Musculoskeletal disorders (MSDs) represent a substantial burden for postmenopausal women, contributing significantly to morbidity and reduced quality of life on a global scale. The menopausal transition is marked by a dramatic decline in sex hormones, principally estrogen, which plays a critical role in maintaining bone density, cartilage integrity, and musculoskeletal function. The resultant hormonal deficiency accelerates bone loss, heightens the risk of osteoporosis and fragility fractures, and predisposes to osteoarthritis and sarcopenia. This abstract explores the clinical relevance of hormonal therapies in the prevention and management of MSDs in menopausal women, with a focus on evidence-based strategies.

The presentation will review the mechanisms by which estrogen deficiency disrupts bone remodeling and connective tissue homeostasis, leading to increased susceptibility to musculoskeletal pathology. Hormone replacement therapy (HRT) remains the gold standard for preserving bone mineral density and reducing fracture risk in this population. Clinical trials consistently demonstrate the efficacy of HRT in mitigating bone loss and providing symptomatic relief for joint pain and muscle weakness. Additionally, selective estrogen receptor modulators (SERMs) and novel endocrine agents offer promising alternatives for women with contraindications to traditional HRT, expanding the therapeutic landscape.

The benefits and potential risks of menopausal hormone therapy are discussed, emphasizing the importance of individualized treatment plans based on patient risk profiles and preferences. Integrating hormonal interventions with lifestyle modifications forms a comprehensive approach to musculoskeletal health. Ultimately, the presentation will highlight the pivotal role of menopausal hormone therapies in the prevention and treatment of MSDs, advocating for their considered use within a multidisciplinary framework to optimize outcomes for postmenopausal women.

PL5

EN ROUTE TO A GLOBAL SARCOPENIA CONSENSUS

A. J. Cruz-Jentoft[1]

[1]Servicio de Geriatría. Hospital Universitario Ramón y Cajal (IRYCIS), Madrid, Spain

Around 2010, consensus meetings held on different continents published updated definitions of sarcopenia. Despite slight variations, these definitions agreed on including muscle function (typically defined as low muscle strength and/or low body physical performance) within the concept of sarcopenia, rather than using the term as a synonym for low muscle mass. Consequently, sarcopenia was conceptualised as an organ insufficiency (muscle failure) characterised by reduced muscle mass, low muscle strength, and reduced physical performance, with different frameworks and cut-off points being used. This functional redefinition swiftly demonstrated clinical significance, propelling research that established the predictive capacity of sarcopenia for critical outcomes such as mortality, disability and falls. These new findings were incorporated into a second wave of key sarcopenia definitions that emphasised the pivotal role of muscle strength in this condition.

However, disparities in definitions among continents are hindering research and the universal integration of sarcopenia detection and management into routine clinical practice. Additionally, incorporating new disciplines into sarcopenia research, where body composition assessments (typically via CT scans) are available but functional measures are lacking, has led to the erroneous attribution of the term 'sarcopenia' to describe reduced muscle mass. This is incorrect, as low muscle mass is also a defining feature of malnutrition and cachexia.

Encouragingly, major consensus groups have come together as part of an initiative called the Global Leadership Initiative in Sarcopenia (GLIS). This collaborative effort has produced an updated conceptual definition of sarcopenia that can be applied globally. An operational definition based on the results of three working groups aiming to define how to measure muscle mass, muscle strength and sarcopenia outcomes is currently being finalised. These advancements, together with expected future developments, will be presented at the conference.

PL6

NUTRITIONAL STRATEGIES FOR OPTIMAL MUSCLE HEALTH

B. Dawson-Hughes[1]

[1]Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, United States

Many nutrients influence muscle performance, but I shall focus on two for which optimal intake remains controversial despite extensive study, protein and vitamin D. These nutrients are often viewed in the context of the well-recognized relationship between intake and physiological function. In this model, both inadequate and excess intake of the nutrient have adverse physiologic consequences and the plateau range between these extremes is optimal. Identifying that plateau region is the challenge.

Scientific literature addressing the extent to which protein intake influences muscle function, despite being widely studied, is challenging to synthesize and interpret. This is due to many factors, including the age and physical activity level of the participants studied, the type of protein ingested, the timing of protein ingestion, the fact that most studies are small, and other factors. I will give examples of these determinants but will focus on protein intake in the general older population. The multifaceted link between protein intake and function makes observational studies particularly challenging and exposed to residual confounding. The recently published US Dietary guidelines for 2025-2030 changed the previous recommendation of 0.8 gm/kg/d to 1.2 – 1.6 g/kg/d for the general population. This has caused quite a stir among well-respected scientists, in part because it may encourage an excess intake of saturated fat in those who choose meat as their main protein source.

Vitamin D deficiency has been linked to muscle since 1922, when E. V. McCollum ultimately identified the causal substance that cured rickets

and named it vitamin D. Here too, multiple observational studies report a positive association between the circulating 25(OH)D level and muscle performance. However, clinical trials have not confirmed the findings of observational studies. As with protein studies, the outcome of clinical trials depends heavily upon the baseline vitamin D status of individuals, on the vitamin D dose, the dose schedule, and other factors. While deficiency is clearly disadvantageous to muscle, there is increasing evidence that excess vitamin D stimulates FGF23, an osteokine that sets in motion a counterregulatory sequence that ultimately diminishes $1,25(OH)_2D$ levels and activity. FGF23 increases the circulating levels of parathyroid hormone and lowers the circulating level of phosphate, both of which contribute to muscle weakness. A current challenge is to identify the optimal 25(OH)D range for muscle function more precisely, so that deficiency and excess can be agreed upon and avoided.

PL7
STATE OF THE ART: ADVANCES IN OSTEOARTHRITIS IMAGING

F. Eckstein[1,2], W. Wirth[1,2]

[1]Center of Anatomy and Cell Biology & Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Paracelsus Medical University Salzburg, Salzburg, Germany; [2]Chondrometrics GmbH, Freilassing, Germany

Objectives
Osteoarthritis (OA) is a debilitating disease affecting > 500 million patients worldwide, yet no therapies are currently available that modify joint structural pathology. This presentation summarizes recent advances in clinical OA imaging, with a focus on quantitative methodologies and on emerging fully automated analysis technologies based on artificial intelligence (AI). Such automated pipelines have the potential to provide scalable, quantitative biomarkers and endpoints for large clinical trials of putative disease-modifying OA drugs (DMOADs) and other interventions, as well as for large-scale epidemiological studies, including those using federated learning approaches. Once effective disease-modifying therapies become available, these biomarkers may also find application in clinical management, supporting diagnosis, prognosis, longitudinal monitoring of treatment efficacy, and identification of responders and non-responders.

Methods
We focus on quantitative imaging biomarkers in OA, specifically cartilage morphology (thickness, volume, surface areas), cartilage composition (MRI transverse relaxation time, T2), and inflammation, including quantitative assessment of Hoffa synovitis using radiomics and effusion-synovitis using morphometry. Imaging of the meniscus, bone, muscle, and adipose tissue is also briefly addressed. Beyond technical validation, we emphasize clinical validation by applying these techniques in studies demonstrating clinically relevant effect sizes, and by comparing established gold-standard methods with novel fully automated approaches.

Results
Imaging biomarkers, such as cartilage morphology, cartilage composition (T2), or synovitis are amenable to fully automated analysis by convolutional neural network (CNN)-based AI algorithms. These approaches demonstrate fair to good agreement with semi-quantitative reading or expert manual segmentation, including quality control. Illustrative applications of these biomarkers will including how they predict and monitor (radiographic/symptomatic) OA progression vs. non-progression, how they differentiate patients with subsequent knee replacement from those without, and other clinically relevant use cases.

Conclusions
Quantitative imaging biomarkers are expected to assume an increasingly important role in OA diagnosis, prognosis, and longitudinal disease monitoring. Given that clinical outcomes require prohibitively large sample sizes for regulatory approval of putative DMOADs, scalable quantitative imaging endpoints offer a realistic pathway toward surrogate endpoint acceptance by regulatory agencies. Such acceptance could substantially accelerate DMOAD development via expedited approval pathways for this serious disease, analogous to the recent (12/2025) acceptance of DXA-based endpoints for osteoporosis drug approval.

PL8
NOVEL EMERGING THERAPIES FOR OSTEOARTHRITIS

I. K. Haugen[1]

[1]Professor, Institute of Clinical Medicine, University of Oslo, Oslo, Norway

There are no approved disease-modifying drugs for osteoarthritis, and there are limited treatment options for this painful and disabling disease. Recently, successful trials on both hand and knee osteoarthritis have been performed, showing benefits of methotrexate, which is currently used for treatment of a variety of other rheumatic diseases. Novel drugs for weight loss, i.e. GLP1-receptor agonists, have demonstrated tremendous pain reduction in knee osteoarthritis patients with overweight/obesity with effect sizes larger than any approved non-surgical therapy for osteoarthritis. Several ongoing Phase 3 trials provide hope for the approval of disease-modifying therapies for osteoarthritis.

PL9
KEY CHALLENGES FOR GLOBAL FRACTURE PREVENTION INITIATIVES

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Most guidelines for the management of osteoporosis and bone health in older age focus on treatment of individuals who experience a fragility fracture and case finding for risk assessment based on the presence of clinical risk factors. However, in many settings the majority of individuals at high fracture risk do not experience appropriate assessment and treatment. This is the case in most high-income countries. Across many low and middle-income countries, heterogeneity in care may be even more stark, potentially being undertaken without access to bone density scanning or even oral bisphosphonates in some settings. Traditional approaches to fracture care which do not incorporate prevention of future fractures may also complicate the picture. In this presentation, I will review the magnitude of, and heterogeneity within, the osteoporosis care gap worldwide, investigating barriers to achieving equitable access to bone health management globally. I will then set out possible solutions to achieving this goal, as published in a recent IOF Position Paper, endorsed by 89 societies around the world.

PL10

IMAGING-BASED OPPORTUNISTIC DETECTION FOR FRACTURE PREVENTION

B. Abrahamsen[1]

[1]Faculty of Health, University of Southern Denmark and Department of Medicine 1 Holbæk Hospital, Holbæk, Denmark

Identification of prevalent and incident fractures is critical to identify patients at very high risk of subsequent, preventable fractures. This is the concept we know as tertiary prevention in osteoporosis and which is addressed by fracture liaison services (FLS) as well as by opportunistic fracture detection and by mining text records. While hip, forearm and humerus fractures are not often missed, only 1/3 of vertebral fractures(VF) are identified. My talk will therefore focus primarily on vertebral and pelvic fractures as this is where the barrier to identification and tertiary prevention is greater. Opportunistic detection may also involve detecting low BMD, typically on CTs or chest x-rays requested on other indications.

Both non-AI and AI based approaches play a role. A familiar example of the former is the addition of VFA to DXA exam in order to screen for vertebral fractures – this requires acquisition of an additional image, taking on the role more of targeted screening (the image is done specifically to find fractures). While CT scans of the thorax and abdomen can and should be reviewed for bone lesions including spine fractures, in practice this is often not done or reported inconsistently. A number of ML tools are now commercially available or in various phases of development. While these tools demonstrate high accuracy[1] and may hold CE (cf https://healthairegister.com/radiology/products) and FDA clearance, some methodological concerns remain and validation of performance in different populations can be limited so that implementation may disappoint. Intended use statements (IUSs) are mandatory for AI based medical devices in the European Union yet often lack important information[2]. Given the low VF identification rate in most services, considerable improvement could be gained even with ML tools that are not perfect in all aspects. However, a clear understanding of the strengths and limitations of such tools is needed for successful implementation in care paths.

OSTEOPOROSIS CARE IN THE CZECH REUBLIC. WHERE WE ARE AND WHERE TO GO

V. Palicka[1,2], R. Pikner[2], M. Bayer[2], L. Bortlik[2], P. Broulik[2], L. Brunerova[2], P. Horak[2], P. Kasalicky[2], S. Kutilek[2], J. Rosa[2], F. Senk[2], V. Vyskocil[2], V. Zikan[2]

[1]Charles University, School of Medicine Hradec Kralove, University Hospital, Osteocentre, Hradec Kralove 9, Czechia; [2]Society for Bone Metabolic Diseases, Czech Medical Association J.E.Purkyne, Czech Republic, Prague, Czechia

Where We Were and Are:

- There were no precise data on the prevalence of osteoporosis in the country. Approximate data from 2019 (WHO) estimate 572,000 cases among the population of over 10 million.
- The economic burden of osteoporosis fractures is very high (21st place among EU27+2 countries).
- A high number of deaths are associated with fracture events (159 per100.000 individuals aged 50 years or older).
- There is a very large diagnostic gap.
- There is a very large treatment gap (79 %).
- Expenditure on osteoporosis care is very low, even though the entire care pathway is covered by health insurance companies.
- There was no official system of care, management was fragmented and provided mainly by endocrinologists, rheumatologists and a small number of orthopaedic surgeons.

What We Did:

- A scientific society dedicated specifically to osteoporosis and other metabolic bone diseases was established (the Czech Society for Metabolic Bone Diseases); it now has more than 200 members.
- A new medical specialisation, **Clinical Osteology,** was created and officially established, accepted and certified by the Ministry of Health and health insurance companies.
- Specialists in Clinical Osteology are authorised to use all diagnostic methods and all types of treatment, which are almost fully covered by health insurance.

What We Have Now:

- A nationwide consensus agreement with the Society of Gynaecologists, the Society of General Practitioners, and all health insurance companies on the "**Population Programme for the Early Detection of Osteoporosis**".
- The screening programme, including treatment, is fully covered by health insurance.
- Screening commenced on 1 April 2023, more than 400.000 individuals have been assessed using FRAX and/or DXA.
- The number of DXA machines covered by health insurance increased from 66 to 214.
- More than 50 % of general practitioners and over two-thirds of gynaecologists are actively involved, using DXA techniques and providing treatment.
- Prescription of bisphosphonates is open to all physicians, denosumab and romosozumab are also available for prescription by gynaecologists.

Where To Go:

- Continue to support prevention, screening programmes, and therapy, including osteoanabolic treatment.
- Place strong emphasis on the development and expansion of the Fracture Liaison Service (FLS) programme.

EL2

CZECH NATIONAL POPULATION PROGRAM FOR EARLY DETECTION OF OSTEOPOROSIS - METHODOLOGY, PRINCIPLES, AND 30 MONTHS RESULTS

R. Pikner[1], V. Palicka[1], P. Dvorak[2], V. Dvorak[3], P. Sonka[4], J. Bodnar[5], H. Seidlova[5], A. Oriskova[5], D. Kostka[6], Z. Salcman-Kucerova[6], S. Strolena[6], P. Nemec[2], K. Hejduk[2]

[1]Society for Metabolic Bone Diseases, Czech Medical Association of J. E. Purkyne, Prague, Czechia; [2]Institute of Health Information and Statistics of the Czech Republic, Prague, Czechia; [3]Czech Gynaecological and Obstetrics Society, Prague, Czechia; [4]General Practitioners Association of the Czech Republic, Prague, Czechia; [5]General Health Insurance Company of the Czech Republic, Prague, Czechia; [6]Ministry of the Interior Public Health Insurance Fund, Prague, Czechia

Objective: The Czech Republic SCOPE scores, published in 2021, resulted in 6th place regarding disease burden and 26th place in combined healthcare provision. Therefore, major professional societies together with major health care payers have prepared and launched the Czech National Population-based Program for Early Detection of Osteoporosis (Program). The Program has started from 1st April 2023. The main aim was to improve osteoporosis detection and care delivery in the country. We present data from the first 30 months of the program.

Methods: National algorithm for DXA indication and monitoring has been proposed. 5 specific reimbursement codes, divided by T-score category (T-score ≥-1.0; -1.1 to -2.0; -2.1 to -2.4; -2.5 to-3.4 and ≥ -3.5), have been created. The code represents lowest T-score reached at L-spine, total Hip and Hip neck from both limbs. 20 DXA per million, 1-2 per district was set as target in 2030. GP´s and gynaecologists have been allowed to perform DXA scans based on mandatory training and have got access to anti-osteoporosis medication. Women at 60 and older, men at 70 and older are indicated for DXA assessment. Furthermore, postmenopausal women up to age 59 and men aged 65-69, if their FRAX exceeds the lower assessment threshold.

Results: We observed 189% increase in DXA devices from January 2023 (118 DXA´s) to 223 to September 2025 (223 DXA´s) in Czechia. This is 20.49 DXA units per million. Regional accessibility has also improved significantly from in 42 of 76 districts (56%) in January 2023 to in 74 districts (97%) in September 2025. Within the period from April 2023 to September 2025 DXA scans were performed in 360 509 women (90%), 76.6 % were older 60 years and in 36 159 men (10%), 90.5 were % older 70 years. We identified 20.99 % women and 11.9% men with T-score equal and below -2.5. We observed expected gradual increase in by T-score defined osteoporosis in women (16.8 % in 60-64 y.; 24.9% 70 y., 37.6 % in

80-84 y). Similar gradient was observed in men.

Conclusion: The Program improved availability of diagnostic care and provide population data. The program is a powerful systematic tool for osteoporosis in Czechia. The program provides important static data to prepare more precise financial plans for osteoporosis care. But it also brings increased demands on continuous education of all healthcare providers.

EL3

DENOSUMAB USE IN ADVANCED CKD PATIENTS: YES OR NO, THIS IS THE DILEMMA

M. Fusaro[1,2]

[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy; [2]Department of Medicine, University of Padova, Padova, Italy

Denosumab, a monoclonal antibody widely used to treat osteoporosis, acts by blocking RANKL and thereby suppressing osteoclast formation. It is not cleared through the kidneys; so, its pharmacokinetics are unaffected by renal impairment, and dose adjustments are not required to maintain safety or tolerability. The relevance of denosumab in patients with age-related renal dysfunction has been examined in several analyses. A post-hoc assessment of the FREEDOM trial evaluated the drug's performance in women with varying degrees of kidney function—73 participants with creatinine clearance between 15–29 mL/min and 2817 with values between 30–59 mL/min, calculated via the Cockcroft–Gault equation. The study found no evidence that kidney function modified the treatment response. Rates of adverse events were comparable across renal function strata, while significant gains in spinal and hip BMD were observed. Moreover, among individuals with an eGFR of 30–59 mL/min, denosumab was associated with a 68% reduction in the odds of vertebral fractures. Further support comes from a retrospective investigation by Iseri and colleagues involving 124 dialysis-dependent CKD patients. Using DXA 3D assessments, they highlighted substantial improvements in BMD, cortical thickness, and biomechanical strength at the hip during the first 3.5 years of therapy. These benefits plateaued thereafter, a pattern that differs from that seen in the general population with osteoporosis, where bone parameters typically continue to rise for up to eight years. As expected, discontinuing denosumab resulted in a gradual decline of the accrued skeletal gains—an effect that makes treatment interruption particularly problematic in the CKD population due to the heightened fracture risk. Consequently, long-term therapy should be considered by physicians before starting denosumab in advanced CKD. Hypocalcemia, ranging from mild to life-threatening, remains the major safety concern when denosumab is used in patients with impaired renal function. Nonetheless, clinical experiences shown in various studies are conflicting; it's fair to state that the drug can be administered safely in advanced CKD-associated osteoporosis provided that patients receive active vitamin D supplementation, maintain sufficient calcium intake, and have dialysate calcium concentrations adjusted appropriately.

EL4

MENDELIAN RANDOMIZATION ROLE OF VITAMIN D IN CORONARY HEART DISEASE

G. Tripepi[1]

[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Reggio Calabria, Italy

Coronary heart disease (CHD) remains a leading cause of morbidity and mortality worldwide, and identifying modifiable risk factors is critical for prevention. Observational studies have suggested an association between low vitamin D levels and increased CHD risk; however, causality remains uncertain due to confounding and reverse causation. Mendelian randomization (MR) leverages genetic variants as instrumental variables to assess causal relationships, minimizing these biases. This lecture will re-examine the role of vitamin D in CHD through a MR study investigating the link between vitamin D–related genetic variants and cardiovascular outcomes in the general population.

EL5

BONE QUALITY IN CKD: HOW TO ASSESS AND WHY IT MATTERS

H. Skou Jørgensen[1]

[1]Dept. of Clinical Medicine, Aarhus University, Aarhus, Denmark

Patients with chronic kidney disease (CKD) suffer from osteoporosis with high risk of fracture. In addition to traditional risk factors, several CKD-specific conditions contribute to bone fragility in this patient population. The bone phenotype in CKD differs from that of post-menopausal or age-related osteoporosis. Several studies have demonstrated disturbed bone microarchitecture in patients with CKD, particularly in the cortical bone department, providing information which goes beyond what is detectable by a regular DXA scan. Further, bone histomorphometry may reveal diverse disturbances in skeletal remodeling, with either very high or very low bone turnover and variable degrees of bone mineralisation

defects. Together, these disturbances contribute to reduced bone quality in CKD. In this lecture we will investigate current options for evaluation of bone quality in CKD, including novel imaging modalities and minimally invasive techniques such as bone microidentation, and the current level of evidence for implementing these in the clinical evaluation of patients with CKD-associated osteoporosis.

EL6

KIDNEY-FRAX®: IS IT THE RIGHT TIME TO PERFORM IT?

J. Bover[1]

[1]Head of the Nephrology Department Hospital Universitari Germans Trias i Pujol (Can Ruti), Badalona, Spain

Bone fragility is a major concern in chronic kidney disease (CKD) because it significantly increases morbidity, mortality, and healthcare costs, and this occurs even before dialysis is initiated. The complex interplay between renal osteodystrophy (ROD), disturbances in mineral metabolism, and changes in both bone quantity and quality lead to increased skeletal fragility and makes clinical assessment of fracture risk in this population particularly challenging.

Importantly, two major developments have "recently" occurred. First, the 2017 revised KDIGO CKD-mineral and bone disorder (MBD) 3.2.1 guideline *suggested* that bone mineral density (BMD) testing may be used to assess fracture risk if results will impact treatment decisions in patients with CKD G3a–G5D with evidence of CKD-MBD and/or risk factors for osteoporosis (evidence level 2B). Second, in 2025, the outcomes of a Controversies Conference on CKD-MBD: "Progress and Knowledge Gaps Toward Personalizing Care" introduced the concept of CKD-associated osteoporosis and emphasized the importance of the heightened fracture risk in patients with CKD.

In this presentation, we will briefly review the ability of FRAX® to identify CKD patients at increased fracture risk and discuss whether FRAX® can truly serve as a practical tool in routine clinical practice. Alternatives such as adjusting FRAX by classifying CKD as a cause of secondary osteoporosis and FRAXplus® will be mentioned. In any case, in order to avoid *renalism*, therapeutic *nihilism* and/or limitation of resources (e.g., densitometry-DXA), FRAX® may be considered a particularly valuable tool in a population in which both fracture risk and the need for treatment are frequently underestimated.

EFFICACY OF INTRA-ARTICULAR HYALURONIC ACID IN OSTEOARTHRITIS

O. Bruyère[1]

[1]University of Liège, Liège, Belgium

Intra-articular hyaluronic acid (IAHA) injections are widely used for the symptomatic management of knee osteoarthritis, yet their clinical efficacy has long been debated due to inconsistent conclusions across systematic reviews and meta-analyses. Clarifying the true magnitude and relevance of IAHA effects is essential to support evidence-based clinical decision-making. Recent high-level evidence, including an umbrella review of systematic reviews and meta-analyses of randomized placebo-controlled trials, indicates that IAHA provides statistically significant improvements in pain and physical function in patients with knee osteoarthritis. Importantly, all systematic reviews of high or moderate methodological quality reported beneficial effects of IAHA compared with placebo. Discrepancies in published conclusions largely stem from differences in methodological quality, restrictive inclusion criteria (e.g. selection of large trials only), and varying interpretations of clinical relevance rather than from an absence of treatment effect. Effect sizes observed across randomized trials are generally small to moderate, but consistent with those of other commonly used osteoarthritis treatments. Evidence suggests that treatment response may be influenced by disease stage, hyaluronic acid formulation, dosing regimen, and timing of outcome assessment, highlighting the importance of appropriate patient selection.

ESCEO2

EXPERT CONSENSUS ON HYALURONIC ACID INJECTIONS FOR KNEE OSTEOARTHRITIS: A PATIENT-CENTERED APPROACH. SAFETY OF IAHA INJECTIONS: CLINICAL OVERVIEW

E. Maheu[1], Ali Mobasheri, Alberto Migliore, François Rannou, Jean-Yves Reginster, on behalf of the ESCEO Working Group on IAHA

[1]Rheumatology unit, St Antoine hospital and private office, Paris, France

Background: Knee osteoarthritis (OA) is a most prevalent degenerative joint disease associated with pain, functional impairment, and reduced quality of life. Hyaluronic acid (HA) is a linear polysaccharide natural component of synovial fluid. Intra-articular (IA) hyaluronic acid injections have been widely used as a symptomatic treatment aimed, since the years 1970's. Their efficacy has been extensively studied. Safety remains a key factor influencing clinical use.

Objective: To evaluate the safety profile of IAHA injections in patients with knee OA.

Methods: Clinical data and published literature were reviewed, focusing on IAHA safety in knee OA, i.e. adverse events associated with HA injections, including local and systemic reactions, incidence rates, severity, and discontinuation due to intolerance.

Results: Most of the literature suggests that IAHA have a positive safety profile despite a few meta-analyses suggesting an increased risk of serious adverse effects.

Hyaluronic acid injections demonstrated a favorable tolerability profile overall. The most reported adverse events (AEs) were mild to moderate post-injections local reactions, including pain at the injection site, transient swelling and redness. Reviews found no major systemic risks with IAHA, reporting only a local AE rate of **~8% (1)** and rare post-injection arthritis. These events were self-limiting and resolved without intervention in most cases. They are common and observed whatever the IA treatment used (including placebo). Severe adverse events, such as acute inflammatory reactions or pseudo-septic arthritis, were rare. Systemic side effects were infrequent. Treatment discontinuation due to intolerance occurred in a small number of patients. No significant safety differences were observed between the different HA formulations. Some metaanalyses outlined that there might be more post-injections inflammatory arthritis with a high molecular weight cross-linked HA preparation (Hylan G-F20), but this was not further confirmed despite the numerous cross-linked preparations launched worldwide since these papers were published.

Few metaanalyses, all from the same team emphasized an unfavourable benefit-risk balance of IAHA, due to a supposed higher rate of severe adverse events compared to placebo (2). Their reporting of safety outcomes appeared to lack consistency and transparency. Notably, they did not assess AEs clinical relevance or causality, a key-issue in a robust safety evaluation. Instead, they referred to their previous meta-analyses, which did not either classify AEs by treatment relationship, leading to potentially misleading conclusions (a motorcycle incident appears in their list). **In contrast,** other reviews found no major systemic risks with IAHA, and sticked to a local AE rate of 8-10%.

Conclusion: IAHA injections are overall well tolerated in patients with knee osteoarthritis, with predominantly mild and transient local adverse effects, underlining their good risk/benefit profile and supporting their use as a therapeutic option in knee OA.

Keywords: knee osteoarthritis, hyaluronic acid, intra-articular injection, IAHA, safety

ESCEO3

NEW PERSPECTIVES IN THE USE OF IAHA FOR THE MANAGEMENT OF OSTEOARTHRITIS

N. Fuggle[1]

[1]Associate Professor, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Intra-articular hyaluronic acid (IAHA) has been used in the management of osteoarthritis (OA) for more than four decades, yet its role in contemporary clinical practice remains debated. Recent advances in trial methodology, large-scale evidence synthesis and a growing emphasis on patient-centred care have prompted renewed evaluation of where, when, and for whom IAHA may offer meaningful benefit. Particular focus on the

well-established concept of a "window of opportunity" in early disease is warranted, where IAHA may contribute to symptom control and functional preservation before irreversible structural damage occurs.

New perspectives are also provided on the expanding landscape of IAHA formulations including combinations with polyols, chondroitin sulphate, corticosteroids, polynucleotides and hybrid molecular-weight preparations. Emerging data suggest that some combination approaches may enhance or prolong clinical benefit beyond IAHA alone, although high-quality comparative trials are a key stepping-stone on research journey.

With new perspectives, as well as with established approaches, it is vital to emphasises the importance of shared decision-making, recognising patient preferences for minimally invasive, non-steroidal therapies with established safety profiles and sustained symptom relief.

Overall, IAHA is a targeted component to be used in the context of multimodal osteoarthritis management.

ESCEO4

GLP-1 RECEPTOR AGONISTS AND MUSCULOSKELETAL HEALTH-INTRODUCTION

G. Bahat[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye

Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are incretin-based therapies that reproduce the physiological actions of endogenous GLP-1, including glucose-dependent insulin secretion, suppression of glucagon release, delayed gastric emptying, and central appetite regulation. Initially developed for the management of type 2 diabetes mellitus, these agents demonstrated consistent metabolic effects and cardiovascular benefit, leading to their widespread clinical adoption.

Subsequent trials demonstrating substantial and sustained weight loss expanded the use of GLP-1RAs to obesity treatment, resulting in a rapid and ongoing increase in their global use. With this expanding utilization, important questions have emerged regarding their potential impact on the musculoskeletal system. Weight loss—particularly when rapid—has raised concerns about possible adverse effects on bone density and skeletal muscle mass. Conversely, experimental and clinical data suggest that GLP-1RAs may exert anti-inflammatory, anti-apoptotic, and tissue-modulating effects that could be beneficial for bone remodeling, muscle quality, and joint health. These apparently divergent mechanisms have generated uncertainty regarding the net musculoskeletal impact of GLP-1RA therapy and highlighted the need for an integrated and evidence-based evaluation, an issue that may be particularly relevant in the context of ageing, vulnerability, and frailty while remaining important across the broader adult population.

In response to these unresolved issues, the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) has established a dedicated working group to critically assess available mechanistic and clinical data on GLP-1 receptor agonists and musculoskeletal health. This symposium presents the findings of this initiative, providing a structured overview of current evidence on bone, muscle, and joint outcomes associated with GLP-1RA therapy.

ESCEO5

GLP1 RECEPTOR AGONISTS AND BONE HEALTH

E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

The prevalence of overweight and obesity is rising across most populations. This is associated with increasing risks of chronic diseases such as hypertension and type 2 diabetes. Excess fat mass has complex relationships with bone health through biomechanical and hormonal pathways, together with effects via chronic inflammation and indirectly through muscle health. GLP1 receptor agonists, originally used in the management of type 2 diabetes, now offer effective routes to improved weight management. Whilst these medications lead to substantial loss of weight, which is predominantly a reduction in fat mass, there appears to be a concomitant reduction in lean mass. Effects on bone health remain inconclusive, but may entail both direct positive effects of these medications on bone cells, and negative effects through the reduced skeletal loading associated with marked weight loss and possible reduction in lean mass. This presentation will review relationships between fat mass and bone health, accounting for muscle, and in particular the direct and indirect implications of GLP1 receptor agonist use for bone density and fracture outcomes.

ESCEO6

GLP1 RECEPTOR AGONISTS AND JOINT HEALTH

A. Mobasheri[1,2,3,4]

[1]Research Unit of Health Sciences and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; [2]Department of Regenerative Medicine, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania; [3]Department of Joint Surgery, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [4]World Health Organization Collaborating Center for Epidemiology of Musculoskeletal Conditions and Ageing, Université de Liège, Liège, Belgium

Objectives: The aim of this presentation is to summarise the current state of knowledge regarding the effects of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) on the musculoskeletal (MSK) system and evaluate their potential relevance for the prevention and treatment of osteoarthritis (OA), osteoporosis (OP), sarcopenia, intervertebral disc (IVD) degeneration and low back pain (LBP).

Material and Methods: This presentation will begin by focusing on the functional aspects of GLP-1 RAs, starting from molecular and cellular mechanisms and then discuss data from preclinical models and clinical studies. There will be a special emphasis on GLP-1 RA effects on joint metabolism, bone turnover, muscle function and spinal health.

Results: GLP-1 receptors are expressed in joint and spine tissues. Agonist activation reduces inflammatory signalling, oxidative stress and catabolic enzyme production in chondrocytes. In OA models, GLP-1 RAs attenuate cartilage degradation and improve subchondral bone architecture. Clinically, weight reduction associated with GLP-1 RAs correlates with decreased knee pain and improved joint function,

although direct structure-modifying effects remain unknown due to the lack of studies integrating imaging and biochemical markers (1). In bone, GLP-1 signalling inhibits osteoclast formation and enhances osteoblast activity, supporting potential protection of bone mineral density during weight loss (2). *In vitro* and preclinical data indicate favourable effects on bone quality and possible fracture risk reduction. In skeletal muscle, lean mass reduction parallels total weight loss, but there is also evidence to suggest that GLP-1 RAs may improve mitochondrial function, insulin sensitivity and intramuscular lipid content, potentially mitigating sarcopenic decline (3). In the spine, GLP-1 RAs exhibit anti-inflammatory and anti-fibrotic actions in preclinical IVD models, suggesting potential benefits for disc degeneration. Clinical observations point to improvement in LBP severity, likely mediated by reduced adiposity, systemic inflammation and mechanical load (4).

Conclusions: GLP-1 RAs demonstrate anti-inflammatory, cartilage and bone-protective effects relevant to OA, OP, sarcopenia and IVD degeneration. However, clinical data remains limited in some MSK diseases. Modern obesity pharmacotherapy is rapidly shifting from single-pathway GLP-1 RAs (e.g., semaglutide) to multi-hormone agonists that stimulate two or three metabolic pathways simultaneously, including other incretin hormones such as glucose-dependent insulinotropic polypeptide 1 (GIP-1). These co-agonists and tri-agonists aim for greater weight loss, improved metabolic health, and reduced plateauing compared with GLP-1 monotherapy. Well-designed, randomised, double-blind, placebo-controlled clinical trials of emerging double and triple agents are needed to confirm musculoskeletal efficacy and clarify long-term safety and efficacy in joint, bone, muscle and spine health. Trials with imaging and biomarker endpoints are required to determine whether GLP-1 RAs, co-agonists and tri-agonists can exhibit true disease-modifying potential and alter disease progression in OA.

ESCEO7

GLP1 RECEPTOR AGONISTS AND MUSCLE HEALTH

G. Duque[1,2]

[1]Dr. Joseph Kaufmann Chair in Geriatric Medicine - Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada; [2]Principal Investigator - Bone, Muscle, and Geroscience Group - Research Institute of the McGill University Health Centre, Montreal, Canada

Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are increasingly prescribed for the management of type 2 diabetes and obesity, with growing use among older adults. Although their metabolic and cardiovascular benefits are well established, concerns have emerged about their effects on skeletal muscle, particularly in populations already at risk of sarcopenia and frailty. This session will critically examine current evidence on the impact of GLP-1RAs on muscle mass, muscle quality, and physical function.

We will review data from clinical trials, real-world studies, and preclinical models assessing changes in lean mass during GLP-1RA therapy, distinguishing quantitative losses from qualitative adaptations in muscle tissue. Emerging evidence suggests that, despite reductions in absolute muscle mass accompanying weight loss, GLP-1RAs may be associated with preserved or improved muscle quality, including enhanced mitochondrial function, improved insulin sensitivity, favorable shifts in muscle fiber composition, and improved muscle perfusion. Potential mechanisms linking GLP-1 signaling to muscle metabolism, inflammation, and neuromuscular function will be discussed.

Finally, the presentation will address clinical implications for older adults, highlighting strategies to mitigate muscle loss, including resistance exercise, nutritional optimization, and individualized prescribing. By integrating mechanistic insights with clinical perspectives, this session aims to provide clinicians and researchers with a clear understanding of the benefits and risks of GLP-1RA therapy for muscle health across the aging spectrum.

ESCEO8

SARCOPENIA: STATE OF THE ART IN DISEASE DEFINITION AND CLINICAL TRANSLATION

A. J. Cruz-Jentoft[1]

[1]Servicio de Geriatría. Hospital Universitario Ramón y Cajal (IRYCIS), Madrid, Spain

Sarcopenia is a progressive, generalised disease of the skeletal muscles, characterised by accelerated muscle mass and function loss. As such, it impairs both muscle morphology and function. Distinctive features include low muscle mass, changes in fibre type composition and increased fat infiltration. It also compromises essential muscle functions such as strength, power and endurance. Like other diseases, it may present both as an acute and chronic condition.

Like other geriatric syndromes, the pathophysiology of sarcopenia is complex. Multiple pathophysiological pathways converge to result in organ failure (in this case, muscle failure). Skeletal muscle plays a multifaceted role that extends beyond movement to include functions such as regulating protein levels, maintaining hormonal balance,

regulating body composition and metabolic processes, facilitating tissue healing, and mediating interactions with adipose tissue and bone. This systemic involvement highlights the wide-ranging clinical implications of sarcopenia.

From an epidemiological perspective, sarcopenia exhibits age-related prevalence and incidence patterns, although it is not exclusive to older populations. An important feature is its potential for spontaneous or treatment-induced reversal. Low muscle mass is also characteristic of other conditions such as malnutrition and cachexia, but sarcopenia is specifically characterised by its functional aspects. Clinical diagnosis relies on specific muscle parameters, particularly measures of muscle strength and morphology, which form the basis of all current definitions. The GLIS initiative aims to standardise these parameters in a global operational definition.

The clinical consequences of sarcopenia are substantial. It significantly impairs physical performance and can lead to further adverse health outcomes, including an increased risk of falls, progressive disability, and an elevated mortality rate. Sarcopenia has a profound impact on quality of life, affecting independence and functional capacity across multiple domains. Recognising sarcopenia as a treatable condition emphasises the importance of early identification and intervention. Healthcare professionals managing older adults and patients at risk of sarcopenia must understand its multisystem effects, diagnostic criteria and clinical consequences in order to implement appropriate preventive and therapeutic strategies.

ESCEO9

DEVELOPMENT OF NOVEL MUSCLE-ACTIVE AGENTS: A REGULATORY PERSPECTIVE

E. Bałkowiec-Iskra[1,2]

[1]Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland; [2]The Office for Registration of Medicinal Products, Medical Devices and Biocidal Products, Warsaw, Poland

Sarcopenia is a severe and debilitating disease, affecting muscles, bones as well as other organs and systems. The condition is age related, and in elderly people it is a common cause of disability, including pain, falls and limitations of activities and participation. Since there is no treatment for sarcopenia approved, an unmet medical need is undisputed. Therefore, there is an urgent necessity for extensive discussions among different stakeholders regarding recommended design of clinical studies aimed to evaluate efficacy and safety of medicinal products for the treatment of sarcopenia. These discussions should take into account heterogeneity of sarcopenia symptoms and be focused on methodological aspects regarding both exploratory and confirmatory clinical studies (including but not limited to selection of a study population, proposed dose, primary and secondary objectives, sample size, optimal duration of both double-blind and open-label study periods).

IOF-ESCEO STRATIFIED FRACTURE RISK APPROACH: ALTERING THE OSTEOPOROSIS TREATMENT PARADIGM

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Osteoporosis and bone health management have advanced substantially in recent decades. We now have an established WHO disease definition, effective mechanisms for fracture risk assessment, and a range of effective treatments. Until recent years, our clinical guidelines have focused on identification of individuals at high fracture risk for anti-osteoporosis treatment. With the advent of anabolic therapies, which have been shown to reduce fracture risk more quickly, and to a greater degree, than oral antiresorptive medications, but generally at greater unit cost, there is a need to most effectively target the most appropriate therapeutic approach to each patient assessed. In this presentation, I will discuss the approach espoused by IOF-ESCEO to targeting treatment choices based on fracture probability calculated using FRAX. Thus, for those individuals at low fracture risk, reassurance, attention to nutrition and physical activity, and potentially menopausal hormone therapy in postmenopausal women, may well be appropriate. For those at high fracture risk, oral or parenteral antiresorptives may additionally be indicated. For those at very high fracture risk, then initial treatment with an anabolic therapy, followed by maintenance with an antiresorptive, is usually the optimal approach. I will present the derivation of this approach and its clinical application, concluding with practical lessons for the clinic.

ESCEO11

SURROGATE MEASURES FOR OSTEOPOROSIS TREATMENT EVALUATION AND IMPLEMENTATION IN THE CONTEXT OF ABSOLUTE FRACTURE PROBABILITY

E. McCloskey[1]

[1]Mellanby Centre for Musculoskeletal Research, Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom

In osteoporosis, the meaningful outcome of effective treatment, for patients, clinicians and regulators, is fracture reduction. However, due to the relatively infrequent nature of osteoporotic fractures and difficulties arising from the fracture risk profile of participants in placebo-controlled or comparator studies, the requirement of such studies for regulatory approval is time-consuming and expensive. For this reason, in many other disease areas, drug development is facilitated by the use of surrogate measures which are deemed capable of evaluating the treatment response.

Increasingly in clinical practice, absolute fracture probability assessed by the FRAX tool provides a framework for who to treat and, more recently, allows stratification within those at increased risk to inform treatment choice. A question is often asked if a tool such as FRAX could also be used to assess treatment response and efficacy; however, to attain the status of a treatment goal, it would need to be highly responsive to osteoporosis

treatment-mediated changes in risk factors. There are obvious limitations to such an approach; for example, age will continue to increase and thus FRAX probability will tend to increase. Furthermore, while an incident fracture can increase fracture probability, there is currently no mechanism by which a prolonged fracture-free interval, mediated by the treatment under investigation, can reduce the estimated probability. Of the FRAX risk factors, bone mineral density (BMD), as a direct skeletal measure, is the most responsive to bone-targeted treatments, and recent meta-regression and individual-patient-data analyses have led to approval by the US FDA of 24-month change in total hip BMD alone as a surrogate endpoint for osteoporosis drug development. However, when combined with important BMD-independent risk factors for fracture, the impact of changes in BMD on FRAX is necessarily diminished. This was demonstrated in a study of 11,049 women from the Manitoba cohort. Over 4 years of follow-up, median FRAX scores showed an increase of 1.1% for major fractures and 0.3% for hip fractures. The authors concluded that FRAX probabilities slowly increased over time, and this increase was attenuated but not completely prevented by treatment.

In summary, few patients have meaningful reductions in FRAX-assessed fracture risk during osteoporosis treatment and FRAX should not be used to monitor treatment response; it can, however, be used to re-evaluate current fracture probability when a change in management is being reconsidered.

ONE FOR ALL? SCORING OF VERTEBRAL FRACTURES?

U. Maus[1,2]

[1]Orthopaedic und Trauma surgeon, Department for Orthopaedic surgery and Traumatology, University hospital Düsseldorf, Düsseldorf, Germany; [2]Department for Orthopaedic surgery, University hospital Cottbus, Cottbus, Germany

Osteoporosis is characterised by an increased risk of fragility fractures and fractures following inadequate trauma. The typical osteoporosis-associated fractures are fractures of the proximal humerus, the distal forearm and the hip. Other typical fractures include vertebral fractures. Vertebral fractures are unique in that the risk of subsequent fractures is influenced by the number and severity of the fractures. Therefore, scoring vertebral fractures is very important in order to correctly assess the risk of subsequent fractures. The most commonly used Genant classification divides fractures into different degrees of severity and allows the risk of subsequent fractures to be assessed based on the result. However, the classification is not suitable for weighing up conservative or surgical treatment options. The AO classification for vertebral fractures in general and the OF classification have become established in Germany. The OF classification was developed specifically for osteoporotic vertebral fractures by a working group of the German Society for Orthopaedics and Trauma Surgery and is recommended in the guidelines for the treatment of osteoporotic vertebral fractures. It distinguishes between different types of vertebral fractures and derives appropriate treatment recommendations from this scoring system. Conservative treatment is recommended for minor vertebral fractures, while surgery is recommended for more severe fractures. For more severe fractures, surgical treatment is recommended, with treatment recommendations ranging from vertebral augmentation to spinal instrumentation. In addition, a dedicated evaluation system supports decision-making.

The AO classification also serves to differentiate between fractures and assist in treatment decisions, but it refers primarily to traumatic fractures rather than osteoporotic fractures. In summary, it can be said that there is currently no scoring system available that allows treatment decisions to be made for vertebral fractures and, at the same time, enables the risk of subsequent fractures to be assessed.

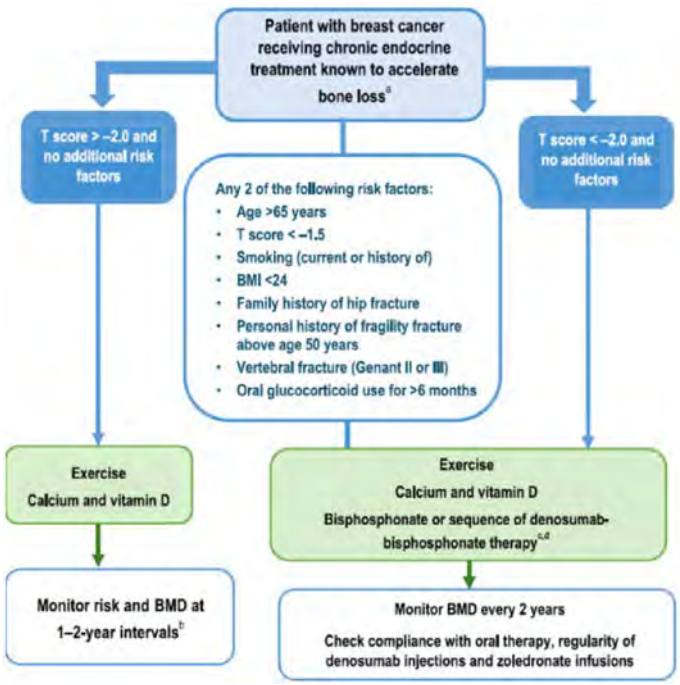
TREATMENT INDUCED OSTEOPOROSIS IN WOMEN WITH BREAST CANCER - THE UPDATED POSITION STATEMENT

P. Hadji[1]

[1]Head of the Frankfurt Bone Health Center, Frankfurt am Main, Germany

Introduction: Osteoporosis is one of the most frequent diseases in postmenopausal women leading to an increased fracture risk due to the physiologic loss of the bone protective effects of estrogen. Hereby, several risk factors for fracture such as prevalent fracture, low BMD, age, family history, use of glucocorticoid use etc. have been identified.



Background: Women with hormone-responsive breast cancer who receive adjuvant endocrine treatment with aromatase inhibitors (AI) are known to be at higher fracture risk due to a marked increase in bone resorption. In 2017, several interdisciplinary cancer and bone societies involved in the management of women with AI-associated bone loss (AIBL) published a joint position statement comprising evidence-based recommendations and a practical management algorithm for the assessment of fracture risk and optimal treatment of this patient population.

Patients and methods: In order to provide updated recommendations that reflect recent advances in the assessment and management of AIBL since publication of the 2017 joint position statement, a systematic literature review was undertaken to identify relevant studies for analysis, including systematic reviews and meta-analyses. Individual trials identified were assessed for their level of evidence based on design, size, follow-up, and evaluation of safety, as well as the impact of bone directed treatments on breast cancer outcomes.

Results: New evidence was combined with the existing recommendations to provide an updated joint position statement regarding fracture risk assessment and implementation of bone-directed therapy.

Conclusion: Current published literature, including recent clinical trial reports, systematic reviews and meta-analyses, continue to affirm the high risk of fractures in women with breast cancer who are receiving adjuvant AI treatment, a risk which has been observed to increase with the commonly used approach of extended duration AI therapy (>5 years). Risk factors for fracture and risk assessment in this patient population as well as the most suitable treatment modalities have been updated. Finally, the influence of bone protective treatments on breast cancer outcomes such as incidence of bone metastasis and breast cancer related overall survival have been included (figure 1).

Figure 1. Recommended algorithm for managing bone health in women receiving aromatase inhibitor therapy for breast cancer. Adapted from Hadji et al, 2017 and Coleman et al, 2020.

[a] Includes AIs and ovarian suppression therapy/oophorectomy.

[b] If patients experience an annual decrease in BMD of ≥10% at any site (or ≥4–5% in patients who were osteopenic at baseline) using the same DXA absorptiometry machine, secondary causes of bone loss such as vitamin D deficiency should be evaluated and antiresorptive therapy initiated.

Use the lowest T-score from spine or hip.

[c] Either denosumab (60 mg every 6 months) or six-monthly intravenous zoledronate (4 mg) as first-line treatment (for the duration of endocrine treatment/together typically for up to 5 years). Discontinuation of denosumab should be followed up by an appropriate antiresorptive.

[d] Weekly oral alendronate (70 mg) or risedronate (35mg) or monthly oral ibandronate (150 mg) for the duration of endocrine treatment/typically for up to 5 years.

Abbreviations: AI, aromatase inhibitor; BMD, bone mineral density; BMI, body mass index.

FRACTURE AND OSTEOPOROSIS - RISKFACTOR, ENDPOINT, COMPLICATION, TREATMENT

A. Kurth[1]

[1]Orthopaedic Institute Dres. Baron& Colleagues and Johann Wolfgang Goethe University, Frankfurt/Main, Germany

Osteoporosis is a systemic skeletal disorder characterized by impaired bone quality resulting in reduced bone strength and an **increased risk of fracture**. **Fragility fractures**, defined as **fractures** resulting from low-energy trauma such as a fall from standing height are central in the understanding of osteoporosis. They represent the clinically significant endpoint of osteoporosis, indicate an increased risk, initiate a number of different trreatment strtategies including surgery, pharamcological treatmen, which might impaire **fracture** healing and post surgery care is mandatory.

This presentation focuses on strategies for identifying, evaluating, and treating adults with **fragility fractures** in order to prevent subsequent **fracture** events and improve functionality of patients..

Clinical relevant endpoint of osteoporosis: A **prior fracture** approximately doubles the relative risk of **future fractures**, with the highest risk observed after hip (femur) and vertebral **fractures**. Risk further increases with the number and severity of previous **fractures,** and additional sites—including the humerus, radius, ankle, and ribs bear a risk of **subsequent fractures.**

Treatment Effects on Fracture: Pharmacologic therapies play a central role in **fracture prevention**. Bisphosphonates reduce hip fracture risk over 36–48 months, while denosumab demonstrates similar benefits over 36 months. Meta-analyses support protective effects for bisphosphonates, denosumab, teriparatide, abaloparartide, and romosozumab. However, prolonged antiresorptive treatment has been associated with **atypical femoral fractures**, likely due to suppressed bone turnover and impaired microdamage repair.

Surgical Considerations: Osteoporotic fractures often require specialized surgical approaches because of compromised bone quality, particularly in elderly patients with multiple comorbidities. Arthroplasty—either total or partial—may be advantageous in cases of femur fractures; hemiarthroplasty, for example, can offer benefits over osteosynthesis in intertrochanteric femur fractures. Minimally invasive procedures such as vertebroplasty and kyphoplasty provide rapid pain relief and structural bone support, although vertebroplasty carries risks of cement leakage and adjacent fractures, while kyphoplasty may reduce leakage risk and improve vertebral height restoration.

Fracture Healing: Fracture healing is a critical determinant of functional recovery. Evidence regarding the negative impact of osteoporosis on fracture healing is derived largely from animal models, with inconclusive clinical data due to confounding factors such as advanced age and comorbidities. Current evidence does not support delaying antiresorptive therapy after acute fragility fractures and surgery or discontinuing ongoing osteoporosis treatment. Teriparatide may shorten healing time at certain anatomical sites, such as the distal radius, but does not appear to affect union rates. Although romosozumab has demonstrated positive effects on fracture healing in animal studies, these findings have not been replicated in humans.

Post-Fracture Care: Despite established diagnostic and therapeutic guidelines, post-fracture care remains suboptimal worldwide. The **Fracture Liaison Service (FLS**) is a multidisciplinary, coordinated model designed to close this care gap by systematically identifying, assessing, and managing patients after fragility fractures. Evidence indicates that FLS programs reduce re-fracture rates, improve treatment adherence and quality of life, and generate significant economic benefits.

Conclusion: Fracture in osteoporosis is a key element in understanding the disease and the treatment. Fragility fractures are a major clinical consequence of osteoporosis and a strong predictor of subsequent fractures. Comprehensive management—including risk assessment, appropriate surgical intervention, pharmacologic therapy and structured post-fracture care—is essential to reduce recurrence and improve patient outcome.

LANDSCAPE FOR INTEGRATED FALLS AND FRAGILITY FRACTURE PATHWAYS ACROSS EUROPE: WHERE DO WE STAND?

N. van der Velde[1]

[1]Academic Director EuGMS, Amsterdam, Netherlands

Fragility fractures constitute a major global health burden and are closely linked to falls, both epidemiologically and clinically. While evidence-based strategies for falls prevention and fracture management are well established, their implementation across healthcare systems and community services remains fragmented. A continuum-of-care approach—linking primary falls prevention, acute fracture management, rehabilitation, and secondary prevention in high-risk populations—is therefore essential to reduce fracture incidence and improve outcomes in older adults.

This presentation will discuss the updated joint position paper from EuGMS, FFN, WFPS, IAGG, and ESCEO–IOF, which builds on the 2016 EuGMS Fracture Prevention Statement and places integrated falls and fracture prevention at its core. Current clinical guidelines will be reviewed, with particular attention to strengthening multidisciplinary care pathways that connect primary care, hospital services, rehabilitation, and community-based falls and fracture prevention programs. Practical strategies will be highlighted for incorporating fracture risk assessment into falls prevention services and for embedding systematic falls assessment within Fracture Liaison Services (FLS), thereby enhancing bidirectional integration between these traditionally separate domains of care.

Beyond clinical practice, the presentation will address the importance of knowledge dissemination and education, emphasizing the need for training programs that prepare healthcare professionals to work across disciplinary boundaries rather than in silos. From a policy point of view, Integrated falls and fracture prevention should be recognized as a public health priority and incorporated into national strategies for healthy ageing, supported by sustainable resource allocation, including in low-resource settings. Finally, key research priorities will be outlined, focusing on the evaluation of effectiveness and cost-effectiveness of integrated care models, as well as on identifying barriers and facilitators to their implementation across diverse healthcare systems and populations.

By aligning clinical practice, education, policy, and research, integrated falls and fracture prevention offers a pragmatic and scalable approach to reducing the burden of fragility fractures and promoting healthy ageing.

EUGMS-IOF-ESCEO2

FALLS AND FRAGILITY FRACTURES IN OLDER ADULTS WITH NEUROCOGNITIVE DISORDERS: PREPARING FOR THE IMPENDING STORM

T. Masud[1]

[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Sixty to eighty percent of people with dementia fall at least once over the course of a year, and forty percent of hip fractures occur in those with dementia. Falls and fractures are also common in other neurodegenerative conditions including Parkinson's disease. The number of persons aged 80 years or older is expected to triple between 2020 and 2050 to reach 426 million worldwide. The societal burden from falls and fractures in the cognitively impaired is therefore going to increase substantially given that the percentage of population with dementia increases from less than 5% in the 70s age range to around 20% in the late 80s and around 30% in the 90s. There is a tri-directional association between dementia, falls and fractures. This talk will explore biological mechanisms that underpin this relationship and will the review the evidence for interventions that reduce falls and fracture risk in this population, and discuss guidelines such as the World Falls Guidelines that can aid clinical management. The multifactorial approach to falls and fracture prevention will be discussed including modification of intrinsic and extrinsic risk factors such as exercise guidelines in this group, deprescribing, medical interventions and environmental modification. The emerging field of the gut-brain axis also opens up new possibilities for future advances. The important role of fracture liaison services and appropriate osteoporosis prevention and treatment in the cognitively impaired will also be discussed.

EUGMS-IOF-ESCEO3

INTEGRATING FALLS AND FRAGILITY FRACTURES SECONDARY PREVENTION: THE SMALL WIN OF THE ORTHOGERIATRIC CARE PATHWAY

M. Bonnici[1]

[1]Department of Geriatric Medicine, Karin Grech Rehabilitation Hospital, Mater Dei Hospital & St Vincent De Paul, Pietà, Malta

Falls and fragility fractures represent interrelated manifestations of frailty, osteoporosis, and multimorbidity in older adults, yet they continue to be addressed through parallel and often fragmented care pathways. While strong evidence supports orthogeriatric (OG) care in improving health-related outcomes after hip fracture, and fracture liaison services (FLS) in reducing subsequent fracture risk, to date limited research evaluated the integration of these models within a single, coordinated pathway.

This presentation reports on the OG pathway as a pragmatic, patient-centred framework for integrating falls and fracture secondary prevention into routine clinical practice. OG care, underpinned by comprehensive geriatric assessment and interdisciplinary collaboration, enables early identification of shared drivers of falls and fractures, including frailty, osteosarcopenia, multimorbidity, polypharmacy, and social and environmental factors.

OG acute management represents a time-critical opportunity to enhance patient awareness and initiate falls and fracture prevention interventions before patients are lost to follow-up.

The presentation highlights how coordinated, patient-centred actions delivered at key transition points can lead to meaningful improvements in clinical and functional outcomes, even in the absence of large, integrated trials. Implementation challenges, existing knowledge gaps, and priorities for future research in integrated orthogeriatric–FLS pathways are discussed, positioning integration as a necessary next step toward truly patient-centred falls and fracture care.

ESCEO-EMAS1

HORMONAL CHANGES AROUND MENOPAUSE AND BONE HEALTH

P. H. Bisschop[1]

[1]Department of Endocrinology and Metabolism, University of Amsterdam, Amsterdam, Netherlands

Menopause marks the end of a woman's reproductive phase and is defined by the final menstrual period. As the follicular reserve declines more rapidly approaching menopause, estradiol levels fall and FSH levels rise. This reduction in estrogen leads to accelerated bone loss, beginning in the late menopausal transition and continuing into early postmenopause. Women with premature ovarian insufficiency (<40 years) or early menopause (<45 years) face a higher fracture risk and require menopausal hormone therapy to mitigate this risk. Even among women reaching menopause at the average age, greater perimenopausal bone loss at the lumbar spine is linked to increased fracture risk. A key challenge is identifying those most susceptible to pronounced perimenopausal bone loss and providing timely hormonal or non-hormonal interventions to prevent excessive bone loss and reduce fracture risk.

ESCEO-EMAS2

BODY COMPOSITION THROUGH MENOPAUSE AND ITS IMPLICATIONS ON BONE

A. Popp[1]

[1]Consultant Bone Metabolism, Division of Diabetes, Endocrinology, Nutritional Medicine & Metabolism (UDEM), Inselspital, Bern University Hospital, Bern, Switzerland

Background: The profound endocrine changes caused by menopause alter body composition and accelerate bone loss in particular. Dual-energy X-ray absorptiometry (DXA) enables concurrent assessment of bone mineral density (BMD) and fat and lean mass, offering insights into musculoskeletal health across this transition.

Objectives: To summarize current evidence on DXA-derived body composition changes through menopause and to describe their implications on bone health.

Methods: A focused synthesis of clinical and epidemiologic evidence using DXA to quantify cross-sectional and longitudinal changes in bone, fat, and lean mass across the climacteric.

Results: During menopause transition lean mass loss and fat mass gain were associated differentially with BMD, both were independently related to more fractures. Consistent with the findings from large cohort studies, that loss of lean mass is related with a greater fracture risk in later life. Longitudinally, increases in appendicular lean mass during early menopause were associated with favorable changes in BMD.

Conclusions: DXA accurately captures changes in bone, fat, and lean mass during menopause. This information allows targeted intervention strategies at the individual level. Consensus is needed on the clinical application of body composition assessment by DXA to establish indications and thresholds for interventions.

ESCEO-EMAS3

EFFECT OF CYCLIC 17-B-ESTRADIOL ON BONE TURNOVER IN POSTMENOPAUSAL WOMEN

E. M. Speksnijder[1], M. W. Tanck[1], D. J. Stenvers[1,2], S. E. Siegelaar[3], P. H. Bisschop[1], M. C. Menopause Consortium[3]

[1]Amsterdam UMC, University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam Gastroenterology Endocrinology Metabolism, Amsterdam Movement Sciences, Meibergdreef 9, Amsterdam, Netherlands; [2]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Endocrinology and Metabolism, Amsterdam Gastroenterology Endocrinology Metabolism, de Boelelaan 1117, Amsterdam, Netherlands; [3]Rien, RIEN, Netherlands

Background: Hormone therapy containing 17- β-estradiol is an effective treatment for the prevention of bone loss in postmenopausal women. We investigated whether restoring a monthly cycle in 17-β-estradiol concentrations is beneficial for bone formation, compared to continuous estradiol administration.

Methods: Healthy postmenopausal women, aged 45-60 years, were randomized to transdermal cyclic, continuous low-dose, or continuous standard-dose transdermal 17-β-estradiol for 16 weeks. The endpoints of the study were the change over time in serum procollagen type 1 N propeptide (P1NP; marker for bone formation) and serum C-terminal telopeptide type 1 collagen (CTX; marker for bone resorption), measured every two weeks.

Results: In the 48 participants, P1NP increased in all groups between baseline and week 4, followed by a decrease between week 4 and week 16. The median decrease in P1NP was less pronounced in the cyclic (-12.6 µg/L (IQR -20.4 – -0.7), p = 0.03) and low-dose group (-12.0 µg/L (IQR -18.4 – 1.8), p < 0.01) compared to the standard-dose group (-15.2 µg/L (IQR -29.1 – -8.7)). CTX decreased between baseline and week 16 in all three groups. The median decrease in CTX from baseline until week 16 was similar in the cyclic group (-143.0 ng/L (IQR -221.3 – -71.2), p = 0.45) compared to the standard-dose group (-157.9 ng/L (IQR -218.9 – -123.2)). However, CTX values remained higher in the low-dose group (-112.2 ng/L (IQR -192.6 – -67.9), p = 0.04) compared to the standard-dose group.

Conclusion: Cyclic 17-β-estradiol administration resulted in higher bone formation over time compared to continuous standard-dose administration, while bone resorption did not differ between the cyclic and continuous standard-dose group. Thus, cyclic 17-β-estradiol may improve bone health compared to continuous administration.

THE ROLE OF OBESITY AND ADIPOSE TISSUE DYSFUNCTION IN OSTEOARTHRITIS PAIN

M. Binvignat[1,2,3], J. Sellam[1,2], F. Berenbaum[1,2]

[1]Rheumatology Department, Saint-Antoine Hospital, Assistance Publique - Hôpitaux de Paris (AP-HP), Paris, France; [2]Sorbonne Université, Centre de Recherche Saint-Antoine (CRSA), INSERM UMRS 938, Paris, France; [3]Immunoregulation, Immunopathology, Immunotherapy I3 Lab, Inserm UMRS 959, Pitié-Salpêtrière Hospital, Sorbonne Université, Paris, France

Obesity is a major, modifiable risk factor for pain in osteoarthritis (OA), with effects that extend beyond mechanical loading or body mass index (BMI). Increasing evidence suggests that obesity exacerbates OA-related pain through a complex interplay of metabolic, inflammatory, and neurobiological pathways, many of which overlap with other modifiable pain-related risk factors. Central to this process is adipose tissue dysfunction, which drives local and systemic inflammation, immune dysregulation, and elevated production of pro-inflammatory cytokines and adipokines, amplifying pain signaling independently of BMI. Among adipokines, leptin has emerged as a potential mediator of OA pain, with serum and synovial fluid levels closely correlating with pain severity after BMI adjustment, whereas the role of adiponectin remains less consistent.

Adipose tissue dysfunction is strongly associated with metabolic syndrome, which contributes to OA pain beyond the effects of excess body weight. The interplay among obesity, metabolic syndrome, and adipose tissue dysfunction modulates multiple pain pathways, including nociceptive, neuropathic-like, and nociplastic mechanisms, through neuromodulators as well as peripheral and central sensitization. These mechanisms likely underlie both the heightened pain burden, and the heterogeneity of pain phenotypes observed in individuals with OA and obesity.

Reflecting this mechanistic complexity, obesity is linked to reduced responsiveness to standard pharmacologic and non-pharmacologic pain management strategies. Interventions that target obesity and metabolic dysfunction therefore represent a promising, yet underexplored, approach to improving pain outcomes in OA. Therapies commonly used for obesity and metabolic syndrome, such as glucagon-like peptide-1 receptor agonists, may provide new opportunities for mechanism-based pain modulation. Elucidating the interconnections among obesity, metabolic syndrome, and OA pain could enable more precise pain phenotyping and inform the development of targeted, individualized therapeutic strategies.

ESCEO-OARSI2

STRUCTURAL CHANGES WITH WEIGHT LOSS IN KNEE OSTEOARTHRITIS

M. Boesen[1]

[1]Professor of Radiology, Copenhagen University Hospital Bispebjerg and Frederiksberg, Copenhagen, Denmark

Obesity is a primary risk factor for knee osteoarthritis (OA), and weight loss is widely recommended as a first-line management strategy to reduce pain and improve function. However, it is still debated if weight loss can significantly modify various joint structure and slow disease progression in the knee measured by imaging.

The presentation will defined the approved imaging structural outcomes and give a brief overview of the literature from the last two decades where Radiographic and MRI derived measurements have evaluated the structural effects of weight loss on knee OA. It will further be discussed if never adjunctive therapies, such as glucagon-like peptide-1 receptor agonists (GLP-1RA) or Bracing as well as new AI derived imaging analysis method might enhance the chance of showing improvement or halting the progression of the structural outcomes.

IMPORTANCE OF CO-GERIATRIC MANAGEMENT IN THE TREATMENT OF FRACTURES AROUND THE HIP- IMPACT OF REGULATORY FRAMEWORKS ON CLINICAL OUTCOMES AND SECONDARY PREVENTION

V. A. Koeppen[1]

[1]Department of Orthopaedics and Trauma, Klinikum Freising-Academic teaching hospital in cooperation with MRI and TUM, Germany, Freising, Germany

Objectives: Orthogeriatric co-management (OGC) is an integral component of state-ofthe-art patient care in the treatment of proximal femur fractures in geriatric patients. Manycountries have national guidelines or regulations to standardize care pathways, but thestrictness of their enforcement varies substantially. This literature review analyzes howthese distinct regulatory frameworks affect acute care quality, patient outcomes, andsecondary fracture prevention.Methods: A comparative literature review was performed focusing on differencesbetween Germany's legally binding regulatory framework (Federal Joint Committee, GBA) and the United Kingdom's guideline-based model (NICE).Results: OGC lowers mortality and reduces complication rates. The German G-BA modelis enforced through mandatory certification and external audits, with clinics that do notcomply facing regulatory and financial penalties, up to exclusion from selective carecontracts. Since implementation of the rigorous G-BA model, adherence to surgery within24 hours and early postoperative mobilization is among the highest reportedinternationally.In contrast to Germany's high-quality acute care standards, the country scores lowregarding secondary fracture prevention, with anti-osteoporotic drug prescription rates ofapproximately 11.5%. The UK, on the other hand, reports anti-osteoporotic drugprescription rates of around 50.3%. Although the UK's NICE recommendations are notlegal mandates, adherence to proximal femur fracture guidelines is monitored throughthe mandatory National Hip Fracture Database. To further encourage guidelineadherence, the UK applies a financial incentive via the Best Practice Tariff, a schemelinked to outcome measures in hip fracture care.Conclusions: OGC should be regarded as the clinical standard for optimizing survivaland functional recovery after hip fractures. Nevertheless, a "regulatory mismatch" existswithin the German system: mandatory G-BA requirements excel at standardizing thesurgical phase but do not adequately address the post-fracture osteoporosis treatmentgap. To achieve forward-looking patient care, structured longitudinal pathways forsecondary prevention must be enforced with the same assertiveness as acute carestandards.

SICOT-ESCEO-IOF2

PERTROCHANTERIC FRACTURES – INNOVATIONS AND PITFALLS

M. Hanschen[1]

[1]Professor of Orthopedics and Trauma Surgery, PI Trauma-Immunology, Munich, Germany

Pertrochanteric fractures represent a significant clinical challenge, particularly in the context of an aging population and increasing fracture incidence worldwide. Over the past two decades, advances in implant design, surgical techniques, and perioperative management have substantially improved outcomes. Intramedullary fixation systems, minimally invasive approaches, and enhanced imaging guidance have become central to modern treatment strategies, enabling earlier mobilization and reduced complication rates. Furthermore, innovations in nail geometry, cephalomedullary fixation, and augmented fixation techniques have expanded the indications for surgical stabilization, even in complex and unstable fracture patterns.

Despite these advances, pertrochanteric fracture management remains associated with notable pitfalls. Implant-related complications such as cut-out, cut-through, malreduction, and peri-implant fractures continue to pose challenges, often related to inadequate fracture reduction, suboptimal implant positioning, or poor bone quality. The increasing use of novel technologies, including cement augmentation and navigation-assisted surgery, introduces new learning curves and potential risks if not applied judiciously. Additionally, patient-related factors such as osteoporosis, frailty, and comorbidities significantly influence outcomes and require a multidisciplinary approach.

SICOT-ESCEO-IOF3

FEMORAL NECK FRACTURES IN THE ELDERLY - THERAPEUTIC OPTIONS

C. Von Rüden[1]

[1]Klinik für Unfallchirurgie, Orthopädie und Handchirurgie, Klinikum Weiden und Krankenhaus Tirschenreuth, Weiden, Germany

Femoral neck fractures represent a frequent and clinically relevant injury in the elderly population, often associated with osteoporosis, comorbidities, and an increased risk of morbidity and mortality. The primary therapeutic goal is rapid mobilization while minimizing complications and preserving function. Treatment strategies can broadly be divided into joint-preserving and joint-replacing options, with the choice depending on fracture pattern, displacement, biological age, functional demands, and overall health status of the patient. Joint-preserving procedures, such as internal fixation using screws or dynamic hip systems, are mainly considered for non-displaced or minimally displaced fractures. These approaches aim to maintain the native hip joint and are associated with shorter operative times and less surgical trauma. However, they carry a risk of complications such as nonunion or avascular necrosis, particularly in displaced fractures. Joint-replacing procedures, including hemiarthroplasty and total hip arthroplasty, are commonly recommended for displaced femoral neck fractures in elderly patients. These techniques allow for immediate full weight-bearing and reduce the likelihood of revision surgery due to fixation failure.

Total hip arthroplasty may offer superior functional outcomes in active patients, whereas hemiarthroplasty is often favored in frail individuals. In conclusion, the management of femoral neck fractures in the elderly requires an individualized approach that balances surgical risks, functional expectations, and long-term outcomes to achieve optimal patient care.

SICOT-ESCEO-IOF4

SARCOPENIA AND FRACTURES AROUND THE HIP – NEWEST DATA

C. Ketzer[1]

[1]Department of Trauma Surgery, Klinikum rechts der Isar, Technical 10 University of Munich, Munich, Germany

Background

Over recent years, the understanding of hip-related fragility fractures has evolved from a purely bone-centered condition toward an integrated muscle–bone disease model. Accumulating evidence indicates that sarcopenia is highly prevalent in this population, frequently persists after fracture treatment, and substantially contributes to impaired recovery, complications, and mortality. These insights have driven the emergence of concepts such as osteosarcopenia and muscle–bone–oriented care pathways.

Objective

This abstract critically appraises current evidence on the role of sarcopenia in hip-related fragility fractures and discusses its implications for contemporary treatment strategies and clinical decision-making.

Current evidence

Recent registry- and population-based studies report a substantial increase in hip-related fragility fractures in very old patients, with a shift toward more severe and unstable fracture patterns and persistently poor functional outcomes. Longitudinal cohorts further demonstrate that sarcopenia frequently persists after hip fractures and is independently associated with impaired mobility, higher complication rates, and increased mortality, even in the context of modern surgical and orthogeriatric care.

Conclusion

These findings highlight that, despite growing evidence and emerging concepts, multimodal muscle–bone–oriented strategies are not yet systematically implemented in hip fracture care. In addition to standardized assessment of sarcopenia and structured integration of nutritional, rehabilitative, and orthogeriatric interventions, thorough knowledge of contemporary surgical techniques and appropriate indication setting remains essential to optimize outcomes in this vulnerable patient population.

PHARMACOLOGICAL TREATMENTS FOR OSTEOPOROSIS IN THE OLDEST OLD PERSONS

N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Age is a major determinant of fracture risk and all other things being equal, fracture risk will rise with increasing longevity. Osteoporosis and high fracture risk are therefore lifelong considerations. Our ability to optimally manage bone health in the oldest old is impacted by several considerations. Firstly, there is limited direct evidence for the efficacy of medications in this age group - sadly lack of evidence is sometimes interpreted as evidence of a lack of effect; secondly, despite advances in clinical care and policy, and the enormous efforts of bodies such as the IOF, fractures may still be viewed as an inevitable part of ageing; thirdly, the body's ability to metabolise and handle medications may change with age, leading to the potential for greater risk of interactions, particularly given the frequency with which older individuals receive multiple medications; fourthly, comorbidities such as renal impairment and gastrointestinal dysfunction become more common with increasing age, such that choosing an appropriate medication is less straightforward than at younger ages. In this session I will consider in detail the considerations pertaining to the clinical assessment and management of osteoporosis and high fracture risk in the oldest old. I will address resulting clinical approaches in the context of guidelines and issues of long-term efficacy and safety. The ultimate focus will be on achieving a pragmatic approach to do the best for these vulnerable patients at high fracture risk in older age.

WFS-IOF-ESCEO2

THE INTERPLAY BETWEEN OSTEOPOROSIS, DEMENTIA AND FRAGILITY FRACTURES

C. Ruggiero[1]

[1]Associate Professor Geriatric Section University of Perugia, Perugia, Italy

As populations age worldwide, clinicians increasingly face patients who suffer simultaneously from neurocognitive diseases, particularly dementia and Alzheimer's disease, and musculoskeletal disorders, including osteoporosis, sarcopenia, and fragility fractures. These conditions do not simply coexist, but reinforce one another through overlapping shared risk factors, some biological pathways related to frailty, malnutrition, vitamin D deficiency, sensory deficits, impaired gait, inappropriate polypharmacy, etc, and vicious circles among homeostatic efforts leading to multisystem failure. Despite the clinical significance of the intersection, the intersection between osteoporosis and dementia remains poor attractive in the research and the clinical scenarios.

People with dementia experience 4-5 fold more falls than cognitively intact older adults, and when they fall, they are 3-fold more likely to sustain fragility fractures, most critically a hip fracture. These fractures are not isolated injuries, they trigger cascades of complications leading to permanent disability, which overcomes premature mortality, poor quality of life and enormous strain on healthcare systems, families, and caregivers. The ethical and logistical challenges of surgical management in this population add further complexity.

However, only 5% of people affected by dementia receive adequate assessment and preventive falls and fractures interventions, reflecting a systemic failure to address a well-documented, high-risk group.

Another dimension to be considered is the bone-brain axis suggesting that bone mineral density (BMD) loss and neurodegeneration share common pathological mechanisms. Then, low BMD may serve as an early biological signal of cognitive deterioration, a finding with significant implications for screening strategies. Incorporating osteoporosis assessment and fall risk evaluation into the earliest stages of cognitive impairment workups could enable earlier multimodal interventions, including supervised exercise, vitamin D supplementation, nutritional support, home safety adaptations, polypharmacy rationalization, mobility aids, etc, which may reduce progression and complication risks. Anti-fracture pharmacotherapy, particularly annual intravenous bisphosphonates, offers a safe, evidence-based, and adherence-friendly option well suited to patients with cognitive limitations. There is an urgency for integration: the risks of falls, fractures, and cognitive decline are intertwined and must be addressed together, not in silos across separate specialties.

WFS-IOF-ESCEO3

REDUCING FALLS AND FRACTURES BY MEDICATION OPTIMIZATION

N. van der Velde[1]

[1]Geriatrician Amsterdam UMC and executive board member World Falls Prevention Society, Amsterdam, Netherlands

Falls are among the most common and serious geriatric syndromes and constitute a major pathway to fragility fractures, disability, and loss of independence. They arise from complex interactions between multimorbidity, age-related physiological vulnerability, functional decline, and pharmacotherapy. A substantial proportion of falls and related fractures are medication-related, particularly associated with fall-risk-increasing drugs (FRIDs). Nevertheless, falls remain under-recognised as adverse drug events, and fall and fracture risk are still insufficiently integrated into routine (de)prescribing practices.

This presentation will focus on medication optimisation as a core strategy for reducing both falls and fractures in older adults. Drawing on recent evidence from deprescribing trials, observational studies, and the World Guidelines for Falls Prevention and Management, it will highlight how history of falls and fractures should systematically inform both prescribing and deprescribing decisions. Key recommendations include assessing fall history and fall risk before initiating FRIDs, using validated tools such as STOPP-START and STOPPFall during structured medication reviews, and embedding medication optimisation within integrated falls and fracture prevention interventions across care settings.

In addition, emerging evidence linking medication groups to falls and fracture risk will be discussed, highlighting both fall-related and non-fall-related mechanisms, including effects on bone metabolism, orthostatic hypotension, sedation, gait instability, and impaired balance. Particular attention will be given to cardiovascular, psychotropic, and centrally acting medications, as well as the cumulative impact of polypharmacy.

Finally, common clinical challenges in deprescribing will be addressed, including risk–benefit trade-offs, symptom recurrence, and patient and caregiver concerns. Practical guidance will be provided on shared decision-making, outcome monitoring, and the use of falls and fractures as clinically meaningful endpoints of pharmacotherapy. By reframing falls and fractures as both determinants and outcomes of prescribing, medication optimisation can support safer, more person-centred care for older populations.

PTH, VITAMIN D AND BONE TURNOVER MARKERS FROM THE LABORATORY PERSPECTIVE: MORE THAN YOU CAN EAT!

E. Cavalier[1]

[1]Department of Clinical Chemistry, University of Liège, CIRM, CHU de Liège, Liège, Belgium

Parathyroid hormone (PTH), vitamin D metabolites and bone turnover markers (BTMs) are cornerstone biomarkers in mineral and bone disorders. This session will illustrate how recent analytical advances and improved standardization can refine clinical interpretation beyond a single-result approach. For vitamin D, robust immunoassays remain appropriate for large-scale screening, while LC-MS/MS offers higher molecular specificity for 25(OH)D2 and 25(OH)D3 and enables targeted metabolic profiling when clinically relevant, including 24,25(OH)2D, 1,25(OH)2D and emerging metabolites such as 1,24,25(OH)3D. Combined readouts (e.g., the vitamin D metabolite ratio, VMR) can provide insight into altered catabolism and support interpretation in kidney disease or atypical phenotypes, provided traceability, commutability and pre-analytical control are ensured. For PTH, method-dependent results largely reflect epitope specificity and fragment detection, which is particularly relevant in chronic kidney disease. Targeted LC-MS/MS workflows without immuno-enrichment can deliver peptide-level specificity and may contribute to reference frameworks, with clear definition of the measurand, peptide targets and calibration hierarchy. For BTMs, clinical added value increases when complementary biology is captured: intact PINP and β-CTX as core formation/resorption markers, together with TRAP5b (osteoclast number/activity) and bone-specific alkaline phosphatase (BALP) for mineralization. Practical take-home messages will focus on assay selection, harmonized reporting (reference intervals, reference change values), and concise interpretative comments to support consistent patient management across platforms and settings.

MTE2

SKELETAL MICROARCHITECTURE AND FRACTURE RISK

R. Chapurlat[1]

[1]INSERM UMR 1033-LYOS, Lyon1 Université, Lyon, France

Prediction of fracture risk in individuals older than 50 is challenging because the sensitivity of BMD alone or BMD combined with other risk factors is often low. Non invasive evaluation of microarchitecture using high resolution peripheral quantitative tomography (HRpQCT) has been developed to improve the prediction for fracture, especially in those postmenopausal women who have moderately decreased BMD but who represent the bulk of fragility fractures.

Several prospective cohort studies have measured microarchitecture at the distal radius and tibia in men and women using HRpQCT. Their results indicated that several parameters provided improvement of prediction over BMD alone or FRAX, especially when considering micro finite element analyses results. When all these cohorts data were combined in a large pooled analysis with a large sample of more than 6000 participants (BoMic consortium), these observations were confirmed. The prediction added to traditional risk factors, however, was not substantial. Several studies have attempted to identify subsets of patients who would benefit more from this type of technique. Thus, several phenotypes of bone fragility have been described, based on density and bone size. Also, machine learning techniques can model efficiently the risk of fracture. HRpQCT may also be of interest to improve fracture risk prediction in special populations like diabetics and patients with chronic kidney disease.

The HRpQCT technique is expensive and not widely available, but it might reach specialized clinical practice if machines were produced in larger quantities to decrease costs and if image analyses and fracture risk modeling were easily accessible through artificial intelligence.

FLS: CURRENT GLOBAL CHALLENGES

M. Chandran[1]

[1]MD, FACP, FACE, FAMS, FASBMR, CCD, Senior Consultant and Director, Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, DUKE NUS Medical School,, Singapore, Singapore

Fragility fractures represent a pivotal inflection point in the "osteoporotic career," yet globally, secondary fracture prevention remains fragmented, inconsistent, and frequently ineffective. It has been well established for over four decades that approximately half of patients sustaining a hip fracture have experienced a prior fragility fracture, often months or years earlier, representing missed opportunities for intervention. Fracture Liaison Services (FLS) were developed to address this persistent care gap through a systematic, coordinated approach to post-fracture assessment and treatment.

FLS models, particularly those based on a clinician champion supported by a dedicated coordinator, have demonstrated improvements in fracture risk assessment, osteoporosis treatment initiation, and reductions in re-fracture rates. International frameworks such as the IOF Capture the Fracture® Best Practice Framework (BPF) have provided standardized benchmarks across 13 domains, enabling global mapping, benchmarking, and recognition of FLS performance. To date, over 1250 FLS programs across more than 62 countries have been mapped, underscoring widespread adoption. However, implementation alone does not guarantee long-term success.

This session examines the global challenges that threaten FLS sustainability, drawing on real-world experience and international data. System-level barriers include incomplete fracture identification (particularly vertebral fractures), fragmented care pathways, workforce limitations, insufficient integration with primary care, and lack of long-term funding models. Patient-level challenges, such as poor adherence to therapy and follow-up further erode program effectiveness. Overly complex care pathways risk disengagement, particularly in non-specialist settings.

Sustainable FLS programs require continuous quality improvement, routine auditing, and realistic, measurable key performance indicators rather than aspirational targets. Frameworks such as Plan–Do–Study–Act (PDSA) cycles, process mapping, and performance benchmarking are essential tools to identify care gaps, implement targeted interventions, and reassess outcomes. Importantly, FLS evaluation must extend beyond organizational metrics to include patient-level engagement and outcomes.

In conclusion, breaking the fragility fracture cycle is a global challenge that demands more than awareness or guidelines. Sustainable FLS models must be locally adaptable, minimally disruptive, patient-centred, and embedded within health systems that prioritize long-term fracture prevention. Implementation is only half the battle; sustainability determines impact.

MTE4
MANAGING BONE HEALTH AFTER BARIATRIC SURGERY

B. Cortet[1]

[1]Department of Rheumatology, University-Hospital of Lille, Lille, France

It has been increasingly acknowledged that bariatric surgery adversely affects skeletal health. After bariatric surgery, the extent of high-turnover bone loss is much greater than what would be expected in the absence of a severe skeletal insult.

Patients also experience a significant deterioration in bone microarchitecture and strength. There is now a growing body of evidence that suggests an association between bariatric surgery and higher fracture risk. Although the mechanisms underlying the high-turnover bone loss and increase in fracture risk after bariatric surgery are not fully understood, many factors seem to be involved. The usual suspects are nutritional factors and mechanical unloading, and the roles of gut hormones, adipokines, and bone marrow adiposity should be investigated further. Roux-en-Y gastric bypass (RYGB) was once the most commonly

performed bariatric procedure worldwide, but sleeve gastrectomy (SG) has now become the predominant bariatric procedure.

Accumulating evidence suggests that RYGB is associated with a greater reduction in BMD, a greater increase in markers of bone turnover, and a higher risk of fracture than SG. These findings should be taken into consideration in determining the most appropriate bariatric procedure for patients, especially those at higher fracture risk. Before and after all bariatric procedures, sufficient calcium, vitamin D and protein intake, and adequate physical activity, are needed to counteract negative loss after bariatric surgery.

Several guidelines have been published over the world indicating who should be treated by antiosteoporosis medications after bariatric surgery. These guidelines emphasize the need of treating patients with a past history of fragility fractures. Also, the guidelines recommend to treat patients with higher T-scores compared to patients with bone fragility but without history of bariatric surgery (i.e., T-score ≤-2) Due to the mechanisms of bone loss after bariatric surgery with a huge increase of bone resorption after such a surgery, bisphosphonates represented the first option. Due to the poor absorption of oral bisphosphonates for these patients, zoledronic acid is recommended as a first line option and few data indicated that zoledronic acid can prevent bonne loss particularly at the lumbar spine. However, the effect seems to be less marked at the total hip.

Denosumab seems also to be a relevant option. One study indicated that this option is effective for preventing bone loss at all the sites. The prevention of the rebound effect when the treatment is stopped should also be taken into consideration.

At the stage further studies are needed to precise the best option and the optimal duration of antiosteoporosis treatment in this population.

MTE5
SCREENING FOR HIGH FRACTURE RISK

E. McCloskey[1]

[1]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Systematic approaches to improving the management and treatment of patients with osteoporotic fractures are increasingly advocated in many countries, reflected in the continuing and rapid expansion in Fracture Liaison Services under the IOF Capture the Fracture initiative. Nonetheless, many patients with past fractures remain unidentified and so untreated, and contribute to a large pool of patients in the general community at high risk of fragility fracture. Here, in primary care, the biggest barrier to effective reduction in fracture rates remains the low awareness of high fracture risk amongst primary care physicians leading to marked under-identification and low treatment rates. This large and persistent treatment gap raises the question if it is now time to consider systematic approaches for the identification of high fracture risk in the wider primary care setting, including the establishment of population screening or enhanced case-finding programs. This MTE session will discuss the possible solutions and examine the barriers to implementation.

MTE6
RARE BONE DISEASES FOR THE OSTEOPOROSIS PHYSICIAN

M. L. Brandi[1]

[1]FIRMO Foundation, Italy and McMaster University, McMaster, Canada

A decade ago rare bone disorders were managed mainly by pediatricians, who were in charge for the severe conditions expressed prenatally, at birth or in childhood. The osteoporosis doctors, also named *bone doctors*, were not interested in skeletal rare disorders, simply because the recognition of these diseases in adults can be a specific and also because the use of genetic tests in the adult patient population was not routinely used.

The International Osteoporosis Foundation (IOF) initiated more than a decade ago a worldwide program of education on these disorders among *bone doctors* with dedicated courses, symposia, lectures, webinars, and publications, mainly dedicated to less severe forms of the disease that should be recognized later in life because of bone fragility. This action continues and today we can witness not only the growth of interest towards these disorders by our doctors, but also their increasing interest to know about the management of patients that are diagnosed in the adult age.

With the increase of clinical studies dedicated to these disorders, the *bone doctor* becomes central in the recruitment of adult patients. This contributes immensely to increase his/her knowledge in the field.

In this presentation, the diagnosis and management of disorders that the *bone doctor* can encounter in his/her clinical activity will be reviewed and discussed in depth

MTE7

META-ANALYSIS: MAKINGS SENSE OF UMBRELLA AND NETWORK APPROACHES

C. Beaudart[1]

[1]University of Namur, Namur, Belgium

Meta-analyses play a central role in evidence-based medicine by synthesizing data from multiple studies to inform clinical and policy decisions. Beyond traditional pairwise meta-analyses, advanced approaches such as umbrella reviews and network meta-analyses have gained increasing prominence, offering broader and more nuanced perspectives on complex bodies of evidence. This meet-the-expert session aims to provide participants with a comprehensive and practical understanding of these advanced meta-analytical frameworks and their place within the broader meta-synthesis landscape.

The session will first situate umbrella and network meta-analyses within the hierarchy of evidence, highlighting their respective objectives, methodological foundations, and relevance for geriatric and clinical research. Key statistical and methodological concepts—including effect size interpretation, heterogeneity, indirect and mixed comparisons, ranking of interventions, and assessment of bias—will be discussed to facilitate critical appraisal and appropriate application of these methods. Particular attention will be paid to the strengths, limitations, and potential pitfalls inherent in complex evidence synthesis, as well as strategies to enhance robustness, transparency, and interpretability.

Drawing on extensive experience in conducting, reviewing, and editing high-quality systematic reviews and meta-analyses, this session will also provide practical recommendations to improve methodological rigor and increase the likelihood of publication in high-impact journals. By integrating conceptual, methodological, and applied perspectives, this meet-the-expert session aims to equip researchers and clinicians with the tools needed to make sense of umbrella and network meta-analyses and to use them effectively in informed healthcare decision-making.

MTE8

EXERCISE: WHAT TO RECOMMEND IN OSTEOPOROSIS

O. Bruyère[1], D. Pinto[2]

[1]University of Liège, Liège, Belgium; [2]Marquette University, Milwaukee, United States

Exercise is a key component of osteoporosis management, with benefits extending beyond bone mineral density (BMD) to fracture prevention, physical function, and fall risk reduction. Evidence supports physical activity as a safe and effective non-pharmacological intervention across the lifespan, including in older adults with established osteoporosis. Weight-bearing and resistance exercises are associated with maintenance or modest improvements in BMD at the hip and spine, while moderate-to-vigorous and impact-loading activities appear particularly osteogenic. Importantly, emerging data show that reducing sedentary behavior and replacing it with even light-intensity physical activity can provide meaningful benefits for bone health, especially in older or frail individuals. Fall prevention is central to fracture risk reduction, as most osteoporotic fractures result from falls. Exercise programs combining balance, functional training, and lower-limb strengthening reduce fall incidence and help counteract fear of falling, which often leads to inactivity and further deconditioning. This Meet-the-Expert session will provide practical, evidence-based guidance on exercise prescription in osteoporosis, including appropriate modalities, intensity, frequency, and progression. Recommendations will emphasize the integration of bone-targeted exercises, fall-prevention strategies, and reduction of sedentary time within an individualized, patient-centred approach to osteoporosis care.

MTE9

MANAGEMENT OF FRACTURE RISK POST-DENOSUMAB

W. F. Lems[1]

[1]Department of Rheumatology, Amsterdam UMC, Amsterdam, Netherlands

Over the years, the number of patients with osteoporosis is gradually growing. As consequence, the number of patients treated for 3 to 5 years with anti-osteoporotic drugs, according to the length of the pivotal phase III-trials, is growing. So, a common question is what to do after initial treatment. Studies with continuing drug treatment, with the same drug or a new drug are scarce. Stopping anti-osteoporotic drugs or a drug holiday is another option. The effects of stopping oral and intravenous bisphosphonates, SERMS, hormonal replacement therapy, anabolics and denosumab will be discussed.

Since the effects of stopping denosumab are alarming, we will zoom in on the pathogenesis of bone loss in patients stopping with denosumab, and discuss which patients have the largest risk of vertebral fractures after stopping denosumab. Finally, we will discuss the necessity of adequate timing of starting of follow-up therapy after denosumab, including the importance of adequate information of patients, and the effects of follow-up medication on bone markers, BMD and vertebral- and nonvertebral fracture rate.

MTE10

MEETING GLOBAL CHALLENGES FOR OSTEOPOROSIS PATIENT SOCIETIES: OSTEOPOROSIS CANADA'S EXPERIENCE SUPPORTING SPREAD OF FRACTURE LIAISON SERVICES ACROSS CANADA

F. Jiwa[1], S. Singh[2]

[1]President and CEO, Osteoporosis Canada, Toronto, Canada; [2]Department of Family Practice, Faculty of Medicine, University of British Columbia, Vancouver, Canada

Objectives: Osteoporosis Canada is the only organization in Canada serving people affected by osteoporosis. The organization works to educate, empower and support individuals and communities on bone and muscle health and on fracture risk-reduction with a strong focus on the spread of the Fracture Liaison Services (FLS) model of secondary fracture prevention. This presentation provides an overview of FLS development and spread across Canada, the successes and continuing challenges, and specific facilitators and barriers that have been identified.

Material and Methods: Information to shape this presentation included: 1) data from Osteoporosis Canada's FLS registry, audit reports and key performance indicator development 2) a summary report of key informant interviews with Canadian FLS leads and 3) historical data on the development and progression of FLS in Canada since 2012.

Results: Significant expansion of FLS programs across Canada has taken place since 2012 with the number of FLS increasing from 30 FLSs in 2 provinces in 2012, to 55 FLSs in 8 provinces in 2026. Facilitating this spread was the Brookfield Chair in Fracture Prevention (2020-2025) that provided start-up funding for new FLSs and the establishment of a national FLS medical lead to develop and sustain structured FLS processes, registry, audit and toolkits. The context of the Canadian healthcare system poses a significant challenge to rapid and integrated FLS spread as oversight of health is regulated by each of the 13 provinces and territories. The 2023 Osteoporosis Canada FLS National audit demonstrated high enrolment of hip fracture patients into FLS programs (median 75%) and high persistence of pharmacologic treatment (median 81%) in fragility fracture patients who are at high risk for re-fracture. Common challenges encountered by FLS programs include: 1) reluctance of patients to initiate anti-osteoporosis medication due to concerns about side effects 2) lack of adequate administrative support for FLS operations, and 3) limited access to bone density testing and specialist support in rural and remote areas of the country.

Conclusions: Osteoporosis Canada has seen tremendous progress in improving access to FLS for Canadian fragility fracture patients. Global collaboration and networking can help support Canada to overcome challenges and to achieve a vision where all fragility fracture patients receive appropriate secondary fracture prevention interventions so that no patients are "left behind".

MTE11

MEETING GLOBAL CHALLENGES FOR OSTEOPOROSIS PATIENT SOCIETIES: THE UK EXPERIENCE IN USING PUBLIC CAMPAIGNING TO SUPPORT THE SPREAD OF FRACTURE LIAISON SERVICES (FLS) AND MAKE OSTEOPOROSIS A HEALTH POLICY PRIORITY FOR GOVERNMENT

C. Jones[1]

[1]Royal Osteoporosis Society, Lower Bristol, United Kingdom

Objectives: The Royal Osteoporosis Society (ROS) is the UK's largest bone health charity. Since 2023, the organisation has campaigned in the four Parliaments of the UK and in the national media for nationwide action to foster Fracture Liaison Service (FLS) set-up and quality improvement. This session will share lessons learned about how to influence national policy to the benefit of osteoporosis patients. Highlights will include the messaging that worked most effectively with political leaders, the campaign tactics that generated the most traction, and the subsequent challenges encountered in holding Ministers to account for promises made to the electorate on osteoporosis care.

Material and Methods: Information to shape this presentation included: 1) data from the FLS Database, the national audit of clinics and their performance; 2) media cuttings from the Sunday Express and Mail on Sunday press campaigns for universal FLS; 3) Quotes and commentary from national politicians which demonstrate that bone health has been mainstreamed as a public health priority, with national plans in place in three of the four nations of the UK.

Results: Between 2020-3, the Royal Osteoporosis Society built the evidence base for the role of FLS in effective fracture prevention through two Parliamentary Inquiries held by its All Party Parliamentary Group on Osteoporosis and Bone Health. A number of Ministerial meetings were held, with good conversations which ultimately changed little to nothing for patients. In 2023, the charity stepped up its public campaigning to hold policy-makers to account for the lack of action to close the treatment gap which left two-thirds of osteoporosis patients without medication. The charity secured the support of the Sunday Express newspaper to launch the "Better Bones" campaign, which has since run for 87 editions and become the longest-running press campaign on record in the UK. ROS also won the support of a rival newspaper, the Mail on Sunday, to launch a parallel campaign for FLS. Together, this media campaign gathered the endorsements of 279 Parliamentarians, as well as business leaders, trade unions, Royal Medical Colleges and patient charities. Results included a commitment in England to roll-out FLS to every part of the country by 2030, as well as a £4.5m investment in new DEXA scanners. In Wales, the First Minister made it a priority to set up FLS in every area and made a ground-breaking public commitment to meet the "80%/50%/80%" clinical standards for FLS by 2030. In Scotland, Ministers agreed to audit their FLS and report publicly on the results. Work in Northern Ireland to replicate these gains is now beginning.

Conclusions: Through highly visible public campaigning, ROS popularised bone health and created a coalition of interests which made the call for universal FLS impossible to ignore. To do this, the charity publicised bone health through the lens of feminism, social justice and fairness, using a new vocabulary to make the cause relevant and relatable for the public at large. Political promises did not immediately translate into action, so further public action to hold government to account was required to ensure good intentions translated into real change. These lessons are likely to translate well to other countries.

MTE12

MEETING GLOBAL CHALLENGES FOR OSTEOPOROSIS SOCIETIES: A SOUTH AFRICAN PERSPECTIVE

T. Hough[1]

[1]National Osteoporosis Foundation of South Africa (NOFSA), Western Cape, South Africa

South Africa is an ageing society. Only 16% of its 60 million people are over the age of 50, and that number is expected to grow substantially over the next 20-30 years. The incidence of osteoporosis and related fractures will therefore increase dramatically. With ageing and urbanization come diet and lifestyle changes, many of which contribute to reduced bone mass.

Nearly half of all South Africans aged 81 and above have osteoporosis.

Meeting global challenges involves a multifaceted approach to improve fracture prevention and post fracture care, improving primary care, promoting health education, ensuring access to diagnostic tools and medication. This requires collaboration between governments, organizations (WHO, UN), healthcare professionals (physicians, nurses, pharmacists), and communities.

Key challenges include our fragile health system, lack of funding, myths

surrounding osteoporosis, and a general lack of awareness that persist in the general population, health care providers, policy makers, and funders.

Key Strategies and Focus areas

- Health Cover for all
- Disease prevention and control
- Access to diagnostic tools and medication
- Development of Health Workforce in bone health programs
- Advancing education and awareness programs
- Addressing health impactors (e.g. urbanisation, lifestyle changes, co-morbidities e.g HIV, obesity, diabetes, malnutrition)

Stakeholders and initiatives

- World Health Organization (WHO)
- United Nations (UN)
- Pharmaceutical Companies
- Private Healthcare
- Dept of Health
- NPO's and NGO's
- Policymakers, healthcare providers and funders

Challenges

- Myths surrounding prevalence of osteoporosis and fractures
- Health inequalities in a 3rd World Country
- Different cultural attitudes toward ageing
- Fragile Health system
- General lack of awareness
- Underutilization of diagnostic tools e.g. FRAX

Addressing these issues remains an ongoing task. Collaboration with other Societies (e.g. Orthopaedics, Gynaecology, Arthritis) is a key-focus, but in a Country where everyone is vying for funding, this is also proving difficult.

NOFSA relies heavily on the success of Awareness Campaigns to educate the public, healthcare professionals, funders and policymakers. These Campaigns are often funded by the few Pharmaceutical Companies left in South Africa.

The situation in South Africa is not unique, but we do have a unique and diverse population which brings about its own challenges.

FRAGILE BONE, FRAGILE CONSTRUCTS? BONE HEALTH ASSESSMENT AND OSTEOPOROSIS THERAPIES IN SPINAL FUSION

M. Chandran[1,2]

[1]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, Singapore, Singapore; [2]DUKE NUS Medical School, Singapore, Singapore

Osteoporosis is traditionally viewed through the lens of fragility fractures; however, its impact extends beyond fracture risk to the structural integrity of bone–implant constructs. In spinal fusion, where mechanical stability and biological fusion must coexist, compromised bone quality can critically influence construct durability. This talk reframes spinal fusion outcomes within a construct-level paradigm, introducing *implant fixation failure* as a unifying endpoint encompassing screw loosening, cage subsidence, pseudarthrosis, and junctional failure. Mechanistically, osteoporosis alters load distribution, reduces cortical thickness, disrupts trabecular architecture, and diminishes material strength, thereby lowering the mechanical margin of safety at the bone–implant interface. Conventional assessment using areal BMD is insufficient to capture these multidimensional deficits. Emerging approaches, including opportunistic CT-derived Hounsfield units, volumetric imaging, and biomechanical modeling offer improved characterization of bone quality relevant to fixation strength. Therapeutically, both antiresorptive and anabolic agents influence construct outcomes, albeit through distinct pathways. Antiresorptives stabilize peri-implant bone and may enhance long-term construct survival, while anabolic therapies demonstrate more consistent benefits in improving fusion mass and accelerating union. However, much of the current evidence relies on surrogate imaging or biomechanical endpoints rather than definitive construct-failure outcomes.

A systematic peri-operative approach to bone health assessment and optimization represents a critical, yet underutilized, opportunity to improve surgical outcomes. Integrating osteoporosis management into spinal reconstruction pathways requires close collaboration between spine surgeons and bone specialists. Future research must prioritize outcome-driven trials to establish definitive links between bone-directed therapies and construct longevity.

CSA-OC2

PTH ANALOG THERAPY IN CKD G4-G5D: CURRENT EVIDENCE AND POTENTIAL ROLE OF ABALOPARATIDE IN ADYNAMIC BONE DISEASE

M. Fusaro[1,2]

[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy; [2]Department of Medicine, University of Padova, Padova, Italy

Patients with advanced chronic kidney disease (CKD stages G4–G5D) face a disproportionately high risk of osteoporosis and fragility fractures, with hip fracture rates up to nine times higher than the general population due to damage prevalent in cortical bone in these patients.

These complications lead to severe functional decline, association with vascular calcifications, cardiovascular disease, and increased mortality, especially in the case of the presence of vertebral fractures. Despite this, a significant therapeutic gap persists due to the historical exclusion of CKD patients from major clinical trials.

Recent data indicate that Adynamic Bone Disease (ABD) has emerged as the primary Renal Osteodystrophy (ROD) subtype, affecting up to 60% of hemodialysis patients. This rising prevalence is largely driven by aggressive management of secondary hyperparathyroidism. In this context of suppressed bone remodeling, bone-forming agents are a compelling therapeutic strategy; by directly stimulating osteoblastic activity, they can effectively mitigate the skeletal fragility inherent to low-turnover states.

While PTH analogs like teriparatide and abaloparatide are established anabolic treatments, their use in stage G4–G5D remains off-label. Abaloparatide, a selective PTH1 receptor agonist, offers a compelling alternative due to its potent bone-building effects and lower risk of hypercalcemia than teriparatide. Abaloparatide has shown the same safety and efficacy in mild CKD patients.

We need further perspective studies.

CROSSTALK OF BONE AND MUSCLE IN AGEING

G. Duque[1,2]

[1]Division of Geriatric Medicine, Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada; [2]Bone, Muscle & Geroscience Program, Research Institute of the McGill University Health Centre, Montreal, Canada

Population aging is accompanied by a progressive decline in bone and muscle mass and function, leading to osteoporosis, sarcopenia, and the increasingly recognized entity of osteosarcopenia. This presentation explores the emerging concept of bone–muscle crosstalk as a central mechanism underlying these interconnected conditions. Rather than functioning as isolated tissues, bone and skeletal muscle communicate through mechanical loading, shared mesenchymal progenitors, inflammatory mediators, and endocrine signals, including myokines and osteokines. With aging, mitochondrial dysfunction, cellular senescence, chronic low-grade inflammation, and impaired anabolic signaling disrupt this bidirectional communication, accelerating functional decline and increasing the risk of falls, fractures, and frailty. Translational evidence from preclinical models and clinical studies highlights common biological pathways that simultaneously regulate bone strength and muscle performance. Targeting these shared mechanisms through physical activity, nutritional optimization, and novel pharmacological interventions offers an integrated strategy to prevent and treat osteosarcopenia. Understanding bone–muscle interactions through a geroscience lens provides new opportunities to preserve intrinsic capacity and extend healthspan in older adults.

A BODY SHAPE INDEX AS A SURROGATE MARKER FOR SARCOPENIA RISK IN POSTMENOPAUSAL WOMEN: A CROSS-SECTIONAL ANALYSIS

N. Şentürk Durmuş[1], A. Yılmaz[2], E. D. Özüdoğru[3], Y. Yıldız[4], Z. Beşışık Yılmaz[4], C. Alkaç[4], B. Can[4], A. Tufan[4]

[1]MD, Geriatrician, Independent Investigator, İstanbul, Türkiye; [2]MD Department of Internal Medicine, Marmara School of Medicine, Istanbul, Türkiye; [3]MD Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Istanbul, Türkiye; [4]MD, Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Istanbul, Türkiye

Background: Hormonal changes and increased central adiposity in postmenopausal women contribute to a disproportionately higher rate of sarcopenia, a condition characterized by the progressive loss of skeletal muscle mass (SMM) and function. Primary care requires simpler screening methods, despite the availability of standard diagnostic tools like imaging and functional testing. A Body Shape Index (ABSI), which uses waist, height, and body mass index (BMI), might reflect central fat accumulation and mortality risk, but its role in sarcopenia prediction remains unclear. To analyze the connection between ABSI and sarcopenia in postmenopausal women, using demographic, metabolic, and body composition data categorized by ABSI quartiles.

Methods: A total of 296 postmenopausal women participated in this cross-sectional study. Sarcopenia was defined according to the EWGSOP2 definition. ABSI was calculated and analyzed in quartiles. Logistic regression identified predictors of high ABSI.

Results: The prevalence of sarcopenia was 43.9% among participants. Participants in the highest ABSI quartile showed significantly older, slower gait speed, and higher rates of osteoporosis and sarcopenia (all $p<0.05$). In the total sample, older age, lower SMMI and slower gait speed were associated with the probability of being Q4 ABSI group ($p<0.05$). In addition, lower SMMI and slower gait speed were independent predictors of higher ABSI in women over 65.

Conclusion: Postmenopausal women with high ABSI show a significant association with poor musculoskeletal and metabolic health. In clinical and community settings, ABSI may offer a cost-effective and simple anthropometric marker for early sarcopenia risk assessment.

Introduction: Fragility fractures impose major economic and social burdens, yet wide global variation in health data systems limits the translation of data into actionable insights and a global fracture risk registry. This policy brief was commissioned and prepared for WHO to advise Ministries of Health on leveraging health data to improve osteoporosis screening, monitoring, diagnosis and prevention, to reduce fracture-related morbidity and mortality.

Methods: Twenty-five global experts were identified with 21 invitations from 16 countries accepted. A total of 11 x one-hour virtual interviews were conducted in October-November 2025. A thematic analysis was conducted, beginning with 15 initial codes derived from the WHO Building Blocks and the PRISM framework, with four additional codes added as new themes emerged. Findings were synthesised into barriers and mutually reinforcing policy opportunities.

Results: Five key barriers consistently identified included (1) low public awareness and competing health priorities, gaps in (2) diagnosis and clinical care, and (3) workforce capability, (4) fragmented and low-quality data, and (5) implementation complexity and sustainability constraints. To address these barriers and challenges, four mutually reinforcing policy opportunities were presented to increase the profile of osteoporosis and fragility fractures (Figure). Experts provided recommendations around (1) importance of local osteoporosis management guidelines, (2) minimum dataset and principles needed for local fracture risk registries, and (3) facilitation and integration of resources including digital solutions (e.g., AI, risk prediction algorithms) to bridge workforce and health equity gaps, including opportunistic case finding.

Conclusion: Findings provide practical, feasible, equitable and scalable recommendations to strengthen data systems, workforce capability and governance for Ministries of Health and stakeholders. Emphasising local context-appropriate guidelines, registries and digital solutions appear key to improving awareness of bone health to prevent fragility fractures.

Figure. Four mutually reinforcing policy opportunities to improve data generation, quality and use for the prevention and earlier detection of osteoporosis and fragility fractures, as well as patient risk assessment. These recommendations are designed to collectively work towards increasing the global profile of osteoporosis and fragility fracture, which is ultimately required for sustainable improvements in patient outcomes.

MULTI-CENTER VALIDATION OF A FEDERATED LEARNING-BASED ARTIFICIAL INTELLIGENCE SYSTEM FOR SCREENING LOW BONE MINERAL DENSITY USING CHEST X-RAYS

W.-C. Hung[1], B.-R. Lin[2], W.-C. Sun[2], P.-W. Wu[2], W.-D. Liu[2]

[1]E-Da Hospital/I-Shou University, Kaohsiung, Taiwan; [2]Taiwan AI Labs, Taipei, Taiwan

Objective

To evaluate the diagnostic performance and generalizability of a novel artificial intelligence (AI) system trained via federated learning for opportunistic screening of low bone mineral density (T-score ≤ -2.5) using routine chest X-rays (CXRs) across two independent medical centers.

Material and Methods

We developed a deep learning model (OsteoPredict) utilizing a federated learning architecture to preserve patient data privacy, trained on 5,943 images. The system was validated retrospectively using an independent external cohort of 3,007 adult patients from two distinct tertiary medical centers who underwent same-day CXR and dual-energy X-ray absorptiometry (DXA). The ground truth was operationally defined as a lumbar spine DXA T-score of ≤ -2.5 for the entire cohort to ensure label consistency for model training. The primary endpoint was the Area Under the Receiver Operating Characteristic curve (AUROC), with sensitivity and specificity as secondary endpoints.

Results

Among 3,007 validation cases, 200 (6.7%) were identified with a T-score ≤ -2.5. The AI system demonstrated excellent discrimination with an overall AUROC of 0.942 (95% CI, 0.923-0.962), a sensitivity of 91.0%, and a specificity of 82.7%. Subgroup analyses revealed robust performance across the two different study sites (AUROC 0.947 and 0.936, respectively) and genders. Crucially, the system maintained high sensitivity in the high-risk elderly population (≥60 years), effectively minimizing false negatives in the group with the higher disease prevalence.

Conclusion

This federated learning-based AI system achieves high accuracy for detecting low bone mineral density (T-score ≤ -2.5) from standard CXRs and demonstrates robust generalization across multiple institutions. By leveraging widely available imaging data, it offers a scalable solution for opportunistic screening, effectively identifying at-risk individuals who may require further definitive DXA assessment.

Acknowledgement

We thank Kaohsiung Veterans General Hospital for providing the validation data. Supported by Taiwan Medical Imaging Co., Ltd. under the A+ Industrial Innovation R&D Program, MOEA, Taiwan.

GLP-1 RECEPTOR AGONISTS AND MUSCULOSKELETAL OUTCOMES: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

C. Beaudart[1], Y. Malréchauffé[1], S. van Heden[1], D. Sanchez-Rodriguez[2], A. Scheen[3], O. Bruyère[4], A. Mobasheri[5], G. Duque[6], R. Rizzoli[7], J.-Y. Reginster[8]

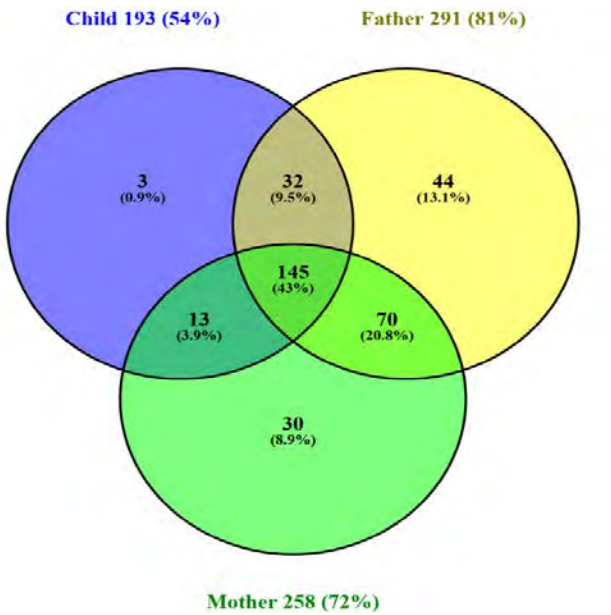
[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), Research Institute for Life Sciences (NARILIS), University of Namur, Namur, Belgium; [2]Department of Geriatrics, Brugmann University Hospital, Université Libre de Bruxelles, Bruxelles, Belgium; [3]Division of Diabetes, Nutrition and Metabolic Disorders, Department of Medicine, CHU Liège, Liège, Belgium; [4]Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium; [5]Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; [6]Bone, Muscle & Geroscience Group, Research Institute of the McGill University Health Centre, Montréal, Canada; [7]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland; [8]Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia

Introduction: This systematic review/meta-analysis aims to synthesize clinical data on the effects of Glucagon-like peptide-1 (GLP-1) receptor agonists (RAs) on key relevant bone, muscle, and joint outcomes. The primary objective is to establish whether these agents are safe for the musculoskeletal system; secondarily, the study examines their potential protective role in mitigating age- and disease-related decline and in improving some key relevant outcomes in musculoskeletal health.

Methods: MEDLINE, Cochrane Central Register of Controlled Trials (CENTRAL) (both via Ovid® platform) and Embase were searched in March 2025 to identify relevant randomized controlled trials (RCTs) or real-world evidence (RWE) studies to be included. This bibliographic search was completed with manual search. A random-effect model meta-analysis was performed for any outcome reported in at least 2 studies. Subgroup analyses were performed on the type of GLP-1 RAs, type of comparator used and study design. Sensitivity analyses were performed to test the robustness of the data. This work has been performed in adherence with PRISMA statement. (PROSPERO Record ID: CRD420251024082).

Results: From 1,148 potentially relevant references, 61 articles (47 RCTs, 13 RWE studies and 1 pharmacovigilance study, combining a total of 1,250,778 individuals) met the inclusion criteria. Different GLP1-RAs were represented across the panel of studies i.e., semaglutide, liraglutide, exenatide, dulaglutide, and tirzepatide (dual agonist GIP/GLP-

1), as well as others such as albiglutide, lixisenatide, and SAR425899 (bamadutide). No effect on bone outcomes (i.e., bone mineral density (all sites) and fractures (all sites) were observed when models included the most adjusted effect size. Regarding muscle outcomes, a significant decrease of lean body mass/fat-free mass was consistently observed with GLP1-RAs in the global model (k=28, SMD0.52, 95%CI -0.8; -0.23, I^2 88%, p-value for heterogeneity <0.0001), which remained robust in all sensitivity analyses. Subgroup analyses showed that the effect was mainly driven by liraglutide and semaglutide, with a decrease in lean body mass/fat-free mass observed when GLP-1 RAs were compared with placebo. No publication bias was found. Regarding joint outcome, models revealed no significant change in WOMAC pain, physical function and stiffness.



Conclusion: This meta-analysis is the first to investigate the effects of GLP-1 RAs on a large panel of musculoskeletal health outcomes. While no effect on bone outcomes and joint outcomes was found, effects on muscle mass outcomes (i.e., decrease of lean body mass/fat-free mass) were observed, apparently in line with body weight reduction. The clinical relevance of these results needs to be firmly established. Further studies in this field, including those looking at muscle function and using multivariate models considering confounding are needed to better reinforce the models and final findings.

FRAGILITY RUNS IN THE FAMILY: INTERGENERATIONAL CLUSTERING OF OSTEOPOROSIS IN A RURAL INDIAN COHORT

L. Nagendra[1], O. Deshmukh[2], C. Yajnik[2], .. On Behalf Of The Pune Maternal Nutrition Study[2]

[1]Department of Endocrinology/JSS Medical College, Mysore, India; [2]Diabetes Unit, King Edward Memorial Hospital, Pune, Maharashtra, India., Pune, India

Objectives

To study the prevalence of osteopenia and osteoporosis across two generations and to examine the extent and pattern of familial clustering of low bone mass in a well-characterised rural Indian birth cohort.

Material and Methods

The Pune Maternal Nutrition Study (PMNS) is a prospective intergenerational cohort established in 1993 in rural western India. Dual-energy X-ray absorptiometry (DXA) measurements of the lumbar spine and femoral neck were obtained in 558 adult offspring (F1 generation), 392 fathers and 502 mothers (F0 generation). Familial clustering was evaluated among 358 complete parent-offspring trios using Venn-diagram-based visualisation.

Results

In the F1 generation, mean age of males was 26 years and of females was 23 years. Mean age of fathers was 53 years, and of mothers was 46 years. In the F1 generation (children), the prevalence of osteoporosis was 5.3% in males and 3.9% in females while osteopenia was prevalent in 49.8% and 50.3% respectively. In the F0 generation (parents), the prevalence of osteoporosis was 32.6% in fathers and 25.1% in mothers while osteopenia was prevalent in 48.7% of fathers and 48.6% of mothers. There was a strong association between BMD of children and parents, both at AP spine and neck of femur.

Among 358 parent-offspring trios, osteoporosis or osteopenia was present in 81% of fathers and 72% of mothers, with 54% of children affected. Notably, 43% of trios showed clustering of compromised skeletal health in all three family members, indicating strong familial aggregation. In 177 (52%), families there was father-child concordance and in 158 (46%) families, there was mother-child concordance, showing no significant parent-of-origin effect (Figure 1)

Conclusion

Familial clustering of compromised skeletal health in this cohort shows that osteoporosis is a life-course trait shaped by inheritance and shared family environments. Beyond genetics, intergenerational factors such as maternal nutrition, fetal growth, and early-life living conditions appear to program skeletal risk. This makes family-centred, early-life intervention a rational and potentially transformative strategy in prevention of fractures.

DEVELOPMENT AND VALIDATION OF DIABETES HIP FRACTURE SCORE (D-HFS) IN PATIENTS WITH TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY OF HONG KONG

D. T.-W. Lui[1], Y. Zhang[1], C. H.-Y. Fong[1], M. Chandran[2], W.-S. Chow[1], K. C.-B. Tan[1], C.-H. Lee[1], Y.-C. Woo[1], K. S.-L. Lam[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong SAR China; [2]Duke NUS Medical School, Singapore, Singapore

Objective: Type 2 diabetes (T2D) is associated with increased risk of hip fracture and post-fracture morbidity. We developed and validated a Diabetes Hip Fracture Score (D-HFS) using population-based electronic health record (EHR) with well-characterised patients with T2D.

Material and Methods: We identified Chinese T2D patients aged ≥40 years who underwent comprehensive diabetes complication assessment during 2008 – 2012 (defined as the index date) in Hong Kong from population-based EHR. Hip fractures were identified by validated ICD-9

code 820. Patients were followed from index date till hip fractures, death, or end of 2023. The cohort was randomly divided 7:3 into development and validation cohorts. D-HFS was build using Fine and Gray model incorporating variables with univariate significance, considering death as competing risk, with model selection based on lowest AIC. Performance of D-HFS was evaluated in validation cohort, and compared with FRAX and other published diabetes-specific hip fracture prediction tools (derived from FDS-I and SIDIAP) using DeLong test.

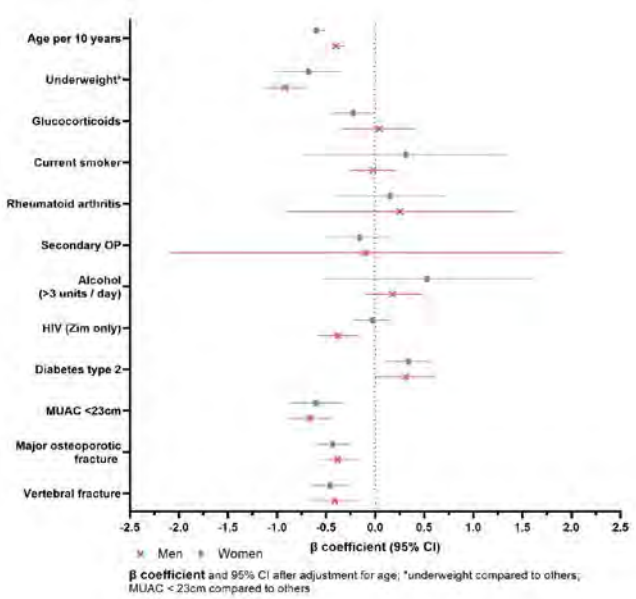
Results: In total, 254,791 T2D patients were included (age 63.8±11.0 years, 49.1% men, BMI 25.7±3.8 kg/m^2). Upon median follow-up of 12.7 years (IQR: 11.1 – 14.3), 11,368 patients had hip fractures (incidence: 3.8 per 1000 person-years). D-HFS consisted of 11 variables: age, sex, BMI, smoking, history of major osteoporotic fractures, history of fall, diabetes duration, HbA1c, eGFR, statin and anti-diabetic medication use. D-HFS performed well in the validation cohort (5-year prediction at optimal threshold 1.51%: AUC 0.838 [95% CI 0.835–0.841], sensitivity 76.5%, specificity 76.4%, PPV 4.0%, NPV 99.6%; 10-year prediction at optimal threshold 3.63%: AUC was 0.822 [95% CI 0.820–0.824], sensitivity 75.2%, specificity 75.2%, PPV 9.0%, NPV 98.9%). Brier score was 0.012 for 5-year and 0.028 for 10-year prediction, suggesting good calibration. D-HFS performed better than FRAX (AUC 0.79), FDS-1 (0.77) and SIDIAP (0.78) hip fracture risk prediction tools (all p<0.001 vs D-HFS).

Conclusion: We developed and validated D-HFS from the largest database of Chinese T2D patients, applicable to electronic clinical management system to facilitate timely fracture risk stratification and preventive strategies to optimize bone health in T2D.

OCs7

LIFESTYLE AND CLINICAL FACTORS ASSOCIATED WITH FEMORAL NECK BONE MINERAL DENSITY IN AFRICAN ADULTS: FINDINGS FROM THE FRACTURE-E3 STUDY

C. M. Pearse[1], L. S. Gates[1], A. J. Burton[2], M. K. Jallow[3], T. Manyanga[3], C. Grundy[4], N. J. Crabtree[5], E. M. Clark[6], H. Wilson[2], A. M. Manyara[2], T. Madanhire[2], B. Cassim[7], R. A. Ferrand[8], C. L. Gregson[2], K. A. Ward[1]



[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Global Health and Ageing Research Unit, University of Bristol, Bristol, United Kingdom; [3]MRC Unit The Gambia, Fajara, Gambia; [4]London School of Hygiene and Tropical Medicine, London, United Kingdom; [5]Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom; [6]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom; [7]Department of Geriatrics, University of KwaZulu-Natal, Durban, South Africa; [8]Biomedical Research and Training Institute, Harare, Zimbabwe

Objective: To identify clinical, nutritional and lifestyle factors associated with femoral neck bone mineral density (FN-BMD) in women and men in Africa.

Methods: A population-based sample of adults aged ≥40 years, stratified by sex and age bands, were recruited in The Gambia and Zimbabwe. FN-BMD was measured using DXA, with vertebral fractures (VF) identified using Genant semiquantitative methods. Linear regression explored associations between demographic, nutritional, lifestyle and clinical risk factors and femoral neck T-scores, stratified by sex and adjusted for age (age-adjusted results shown in the figure). Factors assessed included underweight (BMI <18.5 kg/m^2), low mid-upper arm circumference (MUAC <23 cm), HIV (Zimbabwe only), diabetes, glucocorticoid use, fracture history, rheumatoid arthritis (RA), secondary osteoporosis, smoking and alcohol intake.

Results: The study included 2181 participants (53% women), mean age 61.4 years; 5.8% were underweight and 6% had MUAC < 23 cm. After adjustment for age, markers of undernutrition, low BMI and low MUAC, were associated with lower FN-BMD in both sexes (women (w): β = −0.7 and β = −0.6; men (m): β = −0.9 and β = −0.7, respectively). Previous fractures were also associated with lower FN-BMD (w: VF β = −0.5, MOF β = −0.4; m: VF β = −0.4, MOF β = −0.4). HIV infection was independently associated with lower BMD in men only (β = −0.4), while type 2 diabetes was associated with lower BMD in women only (β = −0.3). Associations for smoking, alcohol intake and secondary osteoporosis seen in unadjusted models were attenuated after age adjustment. Several traditional osteoporosis risk factors, including glucocorticoid use and RA, showed no significant associations, potentially due to low prevalence (4.4% and 0.6%, respectively).

Conclusion: Undernutrition indicators (low BMI and MUAC <23 cm) and prior fractures (MOF and VF) were the strongest correlates of lower FN-BMD, with additional sex-specific associations for HIV (men) and diabetes (women). The absence of associations with several conventional risk factors suggests that in African settings, nutritional status and fracture history may be more informative. Given the limited access to DXA in many African countries, integrating simple anthropometric measures with fracture history may offer a more practical approach to identifying adults at increased fracture risk. Figure. Sex-specific associations between potential risk factors and FN-BMD, after adjustment for age

USING RESEARCH TO TRANSFORM HEALTH POLICY FOR PATIENTS WITH FRAGILITY FRACTURE IN BRITISH COLUMBIA, CANADA

S. Singh[1], L. Funnell[2], J. Solarzano[3], L. Battersby[4], L. Li[1], T. Bubela[4], D. Whitehurst[4], S. Hejazi[5], S. Bayat[3], T. O'Callaghan[5], A. Godfreyson[3], I. Matthes[6], B. Ballantyne[5], L. Matheson-Jennings[5], J. Robinson[3], R. Kherani[1], A. Tecson[5], O. Slavutskiy[5], A. Virk[4]

[1]University of British Columbia, Vancouver, Canada; [2]Osteoporosis Canada, Surrey, Canada; [3]British Columbia Ministry of Health, Victoria, Canada; [4]Simon Fraser University, Burnaby, Canada; [5]Fraser Health Authority, Surrey, Canada; [6]Osteoporosis Canada, Vancouver, Canada

Objective: Fracture Liaison Service (FLS) is an effective post-fracture care model to reduce repeat fragility fractures and improve quality of life for older adults. An implementation science research team successfully implemented the first FLS in British Columbia (BC), Canada and spread FLS to three additional hospitals. The team is now using research methods to integrate FLS into routine orthopedic care in BC.

Material and Methods: The team – health providers, people with lived experience, academics, health sector decision makers and policy makers – brought together expertise in fracture prevention, research methods, patient experience, knowledge translation and health policy. Research methods included: a series of rapid literature reviews relevant to FLS scale-up and spread, a costing analysis of the impact of FLS spread in BC, a comparative policy review case study of FLS in other Canadian jurisdictions and a deliberative dialogue workshop with diverse stakeholders across Canada to provide input to shape the final BC FLS policy options.

Results: Literature reviews and costing analysis confirm that FLS is effective in preventing repeat fractures and associated health care costs. Patient-related factors important for FLS effectiveness include knowledge of osteoporosis, perceived treatment benefits, and trust with health providers. Successful FLS implementation strategies include primary care provider engagement, patient-centred approaches, adapting to local context, adopting team-based approaches, use of virtual technology and a stepwise approach to FLS spread. Barriers to implementation include lack of dedicated funding, shortage of primary care providers and limited experience reaching rural communities and specific populations (e.g., Indigenous peoples). Outputs from our research include 1) a policy brief (Canadian Institutes of Health Research website), 2) a detailed FLS spread business case and implementation plan for BC and 3) integration of FLS spread into the BC Ministry of Health's *Age Forward Strategy* (2024), a prevention-focused health strategy and action plan supporting older adults' needs.

Conclusion: A multi-disciplinary team, that included policy makers, successfully used research methods to transform the health system to benefit patients with fragility fractures.

OCs9

OSTEOSARCOPENIA AND RISK OF ALL-CAUSE MORTALITY FOR COMMUNITY-DWELLING OLDER ADULTS: THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

G. Shafiee[1], N. Fahimfar[2], M. Sanjari[3], K. Khalagi[2], I. Nabipour[4], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]The Persian Gulf Tropical Medicine Research Center, Bushehr University of Medical Sciences, Bushehr, Iran, Bushehr, Iran

Background: Osteosarcopenia is an increasingly recognized geriatric syndrome with a considerable prevalence which increases morbidity and mortality. This study assessed osteosarcopenia as risk factors for all-cause mortality during 7-year follow-up.

Methods: The Bushehr Elderly Health (BEH) Program is a prospective population-based cohort study, which aims to investigate the incidence of non-communicable diseases and their risk factors among people over 60 years old in Bushehr, Iran. Osteopenia/ osteoporosis was defined as a T-score ≤ -1.0 standard deviation below the mean values of a young healthy adult. We defined sarcopenia as reduced skeletal muscle mass index plus low muscle strength and/or low physical performance. Osteosarcopenia was considered as the presence of both osteopenia/osteoporosis and sarcopenia. Participants were categorized in three groups: reference group with no sarcopenia and no osteopenia, sarcopenia or osteopenia group and osteosarcopenia (sarcopenia + osteopenia) group. Hazards ratios (HR) for mortality were calculated with Cox proportional hazards models.

Results: Among 2426 participants, 532 (22.2%) had osteosarcopenia. Over a median follow-up of 7.4 years, 558 (23%) died. Individuals with osteosarcopenia had a significantly higher mortality rate of 52.8 per 100 person-years (95% CI: 45.7-61.0) compared to those without osteosarcopenia, who had a mortality rate of 17.8 per 100 person-years (95% CI: 12.8-24.7). The risk of all- cause mortality among older adults based on osteosarcopenia status, with hazard ratios (HRs) presented across three models. In Model 1 (crude), older adults with osteopenia/ sarcopenia had a significantly increased mortality risk (HR: 1.63, 95% CI: 1.15–2.30), while those with osteosarcopenia exhibited the highest risk (HR: 3.07, 95% CI: 2.15–4.39). After adjusting for age and sex in Model 2, the mortality risk remained elevated in osteopenia/sarcopenia and also osteosarcopenia groups. In Model 3, adjusted for age, sex, body mass index, physical activity, current smoking, protein intake and high fat mass; the highest mortality risk remained in individuals with osteosarcopenia (HR: 1.94, 95% CI: 1.29–2.93), followed by those with osteopenia/sarcopenia group (HR: 1.74, 95% CI: 1.20–2.53).

Conclusion: While sarcopenia or osteopenia increase mortality risk, their combination as osteosarcopenia, is a significant predictor of all-cause mortality among older adults. Therefore, it is important to diagnose and treatment of osteosarcopenia to reduce mortality rate among community-dwelling older adults.

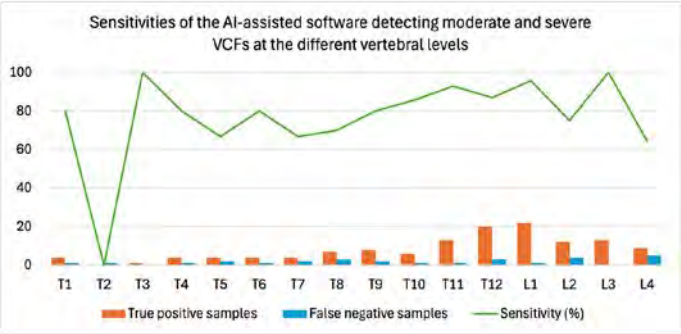
AI-ASSISTED OPPORTUNISTIC DETECTION OF VERTEBRAL COMPRESSION FRACTURES IN CT SCANS

Z. Huang[1,2], R. Bleakney[3,4], A. Kamona[3,4], F. Alavi[2], E. V. Navarro[2], Y. Zhang[2], T. Chung[3,4], H.-J. Jang[3,4], A. M. Cheung[1,2,4]



[1]Department of Medicine, University of Toronto, Toronto, Canada; [2]Department of Medicine, University Health Network and Sinai Health System, Toronto, Canada; [3]Department of Medical Imaging, University of Toronto, Toronto, Canada; [4]Joint Department of Medical Imaging, University Health Network and Sinai Health System, Toronto, Canada

BACKGROUND: Vertebral compression fractures (VCFs), a hallmark of osteoporosis, are often asymptomatic. In this study, we evaluated the diagnostic utility of an artificial intelligence (AI) software for the opportunistic detection of VCFs in computed tomography (CT) scans.

METHODS: This dual-center retrospective study was conducted at the University Health Network, Toronto, Canada. Consecutive thoracic, abdominal and spine CT scans, from January 1–10, 2023 and June 1–10, 2024, were analyzed using Nanox.AI software HealthOST V1.1 1.0.2, if the following criteria were met: age 50 years and above, sagittal scans with at least 4 vertebrae between T1-L4, and availability of a radiology report. All eligible scans were also reviewed by two expert musculoskeletal radiologists. The Genant semiquantitative technique was used, with moderate and severe VCFs corresponding to height reductions of 25%-40%, and greater than 40%, respectively. A scan was flagged as positive if at least one moderate or severe VCF was identified. The results from software and the original reports were compared to those of the expert radiologists (gold standard). If both software and experts flagged it as positive, regardless of the vertebral level(s), the sample was considered true positive for overall diagnostic performance.

RESULTS: Of the 638 consecutive CT scans, 504 satisfied the inclusion criteria and were successfully analyzed. AI software identified 113 scans as positive, and 391 scans as negative for moderate or severe VCFs. Radiologists excluded 11 scans, and validated 493 scans (17 spine, 164 chest, 188 abdomen/pelvis and 124 chest/abdomen/pelvis). The mean age was 69.9 years (SD 11.2), with 47.9% females. The prevalence was 18% by our expert radiologists. The overall sensitivities and specificities of the software were 90% (95%CI: 82%-95%) and 93% (95%CI: 90%-95%) [PPV of 74% (95%CI: 67%-81%) and NPV of 98% (95%CI: 96%-99%)], while those of the original reports were 49% (95%CI 38%-60%) and 99% (95%CI: 97%-100%), respectively. The sensitivities of the AI software at vertebral levels are shown below.

CONCLUSIONS: AI software can enhance the sensitivity of opportunistic detection of moderate and severe VCFs in thoracic, abdominal and spine CT scans, potentially helping radiologists improve reporting accuracy.

MUSCULOSKELETAL AGING IN THE OLDEST OLD: WHEN EAST MEETS WEST

E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Musculoskeletal disorders of aging carry a heavy public health burden globally as osteoporosis and sarcopenia are strongly associated with an increased risk of fragility fractures and falls respectively, and severe osteoarthritis often requires replacement of the affected joint.

Previous work spanning several decades has suggested differences in the prevalence of these conditions in UK and Japanese populations, although common determinants of musculoskeletal aging have been highlighted. Hence in original work that compared cohort members in the seventh decade of life, peak bone mass appeared lower but bone loss rate slower in Japanese populations [1]. In the same population, severe lumbar spine osteoarthritic degenerative change was more common in UK than Japanese populations [2]. Finally, the prevalence of low grip strength was more common in Japanese adults [3]. Demographic changes worldwide have led to change in life expectancy such that life expectancy in the UK is now 83.5 and 79.3 years for women and men respectively while Japanese life expectancy is now 88 and 82 years for women and men respectively.

This symposium therefore revisits this topic to compare muscle, bone and joint aging in oldest old populations in Southampton, UK and Japan, in a cohort of adults mean age > 80 years.

THE ROAD STUDY – AN OVERVIEW

N. Yoshimura[1], T. Iidaka[1], S. Tanaka[2]

[1]Department of Prevention Medicine for Locomotive Organ Disorders, 22nd Century Medical and Research Center, The University of Tokyo, Tokyo, Japan; [2]Department of Orthopaedic Surgery, Sensory and Motor System Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Over the past 60 years, life expectancy in Japan has increased by approximately 30 years, making Japan the country with the longest life expectancy in the world. At the same time, however, this remarkable longevity has brought increased attention to the problem of long-term care dependency. We initiated the ROAD (Research on Osteoarthritis / Osteoporosis Against Disability) study in 2005. The primary objectives of this large-scale, population-based cohort study are to clarify basic epidemiological indices of musculoskeletal disorders and to identify their risk factors. The cumulative number of participants in the ROAD study reached 15,693 (5,164 men and 10,529 women) by the sixth survey, placing it among large-scale population-based cohorts of musculoskeletal disorders.

The ROAD study was conducted in three regions with distinct characteristics—an urban area, a mountainous rural area, and a coastal fishing village. Residents were informed about the health examination (baseline survey) through local newsletters and circular notices and were invited to participate. The baseline survey was conducted between 2005 and 2007, with a total of 3,040 participants (1,350 from the urban area, 864 from the mountainous area, and 826 from the fishing village). The mean age was 70.3 years, and 65% of participants were women. Baseline assessments included a detailed questionnaire consisting of approximately 400 items, a dietary survey, grip strength measurement, gait speed assessment, and comprehensive physical measurements (height, weight, grip strength, arm span, blood pressure, pulse rate, ankle–brachial index, one-leg standing test, chair stand test, gait speed, quadriceps muscle strength, and balance function). Bone mineral density was measured using dual-energy X-ray absorptiometry (DXA). In addition, radiographic examinations of the spine, hip joints, and knee joints were conducted, followed by clinical evaluations by orthopedic surgeons. Follow-up surveys of baseline participants have been conducted at 3, 7, 10, 13, and 17 years after enrollment. Measurement of muscle mass was introduced from the second survey onwards. Screening for hand osteoarthritis began in the third survey.

NSS3

THE SALSA STUDY – AN OVERVIEW

F. Laskou[1], H. P. Patel[1,2,3]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [3]Academic Geriatric Medicine, University of Southampton, Southampton, United Kingdom

The Southampton Longitudinal Study of Ageing (SaLSA) was established to investigate musculoskeletal health, nutrition, physical activity, and functional decline in community-dwelling older adults.

During the first phase of SaLSA, conducted between August 2020 and September 2021 we recruited 516 adults aged ≥75 years from a large primary care practice in Southampton, UK. Postal questionnaires captured sociodemographic characteristics, comorbidities, physical activity, diet, measures of physical frailty and physical activity as well as sarcopenia risk (SARC-F). The second phase of SaLSA was conducted between November 2023 and July 2025. Two hundred and twenty two participants of the original cohort participated in the phase 2 study; of these 193 participants completed a research visit while 29 completed a postal questionnaire only. Research visits included detailed musculoskeletal phenotyping through physical performance measures, grip strength dynamometry, DXA scanning, high-resolution peripheral quantitative computed tomography (HRpQCT), and clinical examination for osteoarthritis.

Participants had a median age of 79.4 years at baseline and high levels of multimorbidity, with over 70% reporting ≥2 chronic conditions. The cohort was primarily Caucasian (99%), The number of participants with frailty (3 or more frailty components) was 7% among males and 14% among females.

NSS4

HOW DOES MUSCULOSKELETAL HEALTH AND ITS DETERMINANTS IN EAST AND WEST DIFFER?

L. D. Westbury[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective Musculoskeletal conditions are common among older people and result in considerable individual and societal costs. However, research comparing the prevalence and correlates of these conditions in Eastern and Western populations is limited. We investigated this among community-dwelling older people from a UK and Japanese cohort.

Materials and Methods Participants were from the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) Study and the Southampton Longitudinal Study of Ageing (SaLSA); the age range in ROAD was restricted to match that of SaLSA. Questionnaires were used to ascertain the following: health behaviours (smoking history, alcohol intake, Physical Activity Scale for the Elderly); number of comorbidities; and musculoskeletal health (osteoarthritis (ever diagnosed), osteoporosis (ever diagnosed); fall in previous year; and fracture since age 45. A poor musculoskeletal health score was derived from the number of the following: osteoarthritis, osteoporosis, and fall in the previous year. Correlates of the musculoskeletal outcomes and the poor musculoskeletal score were examined using logistic and Poisson regression, respectively.

Results Mean (SD) age was 79.7 (4.7) and 81.1 (4.9) years in ROAD and SaLSA, respectively. Prevalence was higher in ROAD compared to SaLSA regarding osteoarthritis (men 52.1% vs 15.9%, women 65.9% vs 31.4%) and osteoporosis (men 8.4% vs 3.0%, women 34.9% vs 19.4%). Fall prevalence in ROAD (men 23.7%, women 23.9%) and SaLSA (men 21.4%, women 28.5%) was similar; fracture prevalence was similar among women (ROAD 38.4%, SaLSA 37.8%) and higher in ROAD among men (28.4% vs 16.7%). In SaLSA, among women, higher BMI and lower physical activity were associated with falls and osteoarthritis, and a worse musculoskeletal score; among men, ever smoking was associated with osteoarthritis and a worse musculoskeletal score. Among both sexes in ROAD, higher BMI was related to osteoarthritis but reduced risk of osteoporosis; lower physical activity was associated with osteoarthritis among women in ROAD.

Conclusion Prevalence and correlates of the musculoskeletal conditions considered differed between the two cohorts. These findings underscore the need for tailored prevention strategies that consider population-specific risk profiles in the development of interventions to reduce the burden of musculoskeletal disorders.

NSS5

MOVE TO IMPROVE: OSTEOPOROSIS, CARDIOVASCULAR RISK, AND THE ROLE OF EXERCISE IN HEALTHY AGING

C. Smith[1]

[1]Nutrition and Health Innovation Research Institute, Edith Cowan University, Perth, Australia

Introduction: Osteoporosis and cardiovascular disease (CVD) are common in older adults. Historically viewed as distinct diseases, with CVD thought to primarily affect men and osteoporosis a disease affecting women. Mounting evidence now links the two through shared risk factors and complex biological mechanisms. Individuals with CVD have a higher prevalence of osteoporosis and fragility fracture risk, while people with osteoporosis have increased risk of cardiovascular events.

Objective: The talk will briefly review the prevalence of CVD in individuals with low BMD or osteoporosis and summarise findings from a systematic review of prospective studies on the prognostic importance of low BMD or osteoporosis for incident CVD. Drawing on 15 years' experience as an Accredited Exercise Physiologist, the presentation will emphasise the importance of exercise for bone and cardiovascular health.

Results: Clinical CVD commonly co-exists with low BMD or osteoporosis, with higher prevalence in individuals with osteoporosis compared to normal or low BMD. Prospective studies indicate that low BMD and/or osteoporosis independently predict incident CVD in older adults, with some showing graded increases in CVD risk across decreasing BMD categories. Exercise provides broad health benefits and is recommended for all, including those with osteoporosis and CVD; however, bone health benefits require specific principles such as weight-bearing, progressive, impact-based exercise. Exercise is also central to falls prevention, reducing falls and fracture risk. While exercise recommendations exist for osteoporosis or CVD individually, targeted evidence-based programs for co-existing CVD and osteoporosis are lacking.

Conclusion: The talk will conclude with practical take-home messages for clinicians to optimise lifestyle approaches. It will summarise evidence on available exercise programs and guidelines for bone and cardiovascular health, emphasising safe implementation in patients with co-existing osteoporosis and CVD. Community perspectives and lived experience will be incorporated to ensure approaches are effective and relevant.

NSS6

BONE-APPÉTIT: INFLUENCE OF CARDIOVASCULAR DISEASE ON MUSCULOSKELETAL HEALTH: A KEY ROLE FOR NUTRITION?

M. Sim[1]

[1]Nutrition and Health Innovation Research Institute, Edith Cowan University, Perth, Australia

Introduction: Cardiovascular disease (CVD) and osteoporosis are leading contributors to morbidity, disability, and premature mortality globally. Previously, considered distinct conditions of ageing, growing epidemiological and mechanistic evidence indicates that CVD and poor

musculoskeletal health frequently coexist and interact, increasing the risk of falls and fragility fractures. Both diseases also share numerous lifestyle risk factors, including poor nutrition, which represents a potentially modifiable pathway linking vascular and musculoskeletal health.

Objective: This session will consider evidence from systematic reviews, large population-based cohorts, clinical registries, guideline audits and mechanistic studies to examine CVD (including subclinical CVD) as a comorbidity for a range of musculoskeletal outcomes; low bone mineral density, poor muscle strength, as well as falls and fracture. These will be covered in the context of shared biological mechanisms that can be positively influenced by nutrition.

Results: Subclinical and clinical CVD are common in people with low BMD and osteoporosis, with consistent evidence demonstrating higher fall and fracture risk in individuals with CVD, independent of traditional risk factors. There is also strong evidence for subclinical CVD, specifically abdominal aortic calcification which can be captured on vertebral fracture assessment images, as a key risk factor for incident falls and fractures. Nutrient-dense dietary patterns, particularly those rich in vegetables, adequate protein, calcium and vitamin K, are associated with favourable cardiovascular and musculoskeletal outcomes. However, there appears to be some conflicting data in the context of plant-based and vegan diets for cardiovascular and musculoskeletal health.

Conclusion: This presentation will provide an overview for clinical and subclinical CVD as an under-recognised but important comorbidity of osteoporosis that contributes to falls and fractures. It will highlight how nutrition plays a central, yet underrecognised, role in addressing shared risk pathways. Integrating cardiovascular risk assessment as part of routine musculoskeletal screening could be a promising opportunity to reduce the global burden of falls, fractures and cardiovascular events.

NSS7

A MODEL OF PATHOGENESIS OF ATHEROSCLEROTIC CALCIFICATIONS AS A CONSEQUENCE OF OSTEOPOROSIS

G. Klein[1], J. R. Lewis[2], S. J. Nicholls[3], J. Amuthavalli Thiyagarajan[4], P. Ebeling[3]

[1]University of Texas Medical Branch, Galveston, Texas , United States; [2]Edith Cowan University, Perth, Australia; [3]Monash University Medical Center, Clayton, Australia; [4]World Health Organization, Geneva, Switzerland

To address the question of whether atherosclerotic vascular calcifications may be pathologically related to osteoporosis, we undertook a scoping review scanning 6344 manuscripts from 4 databases, identifying 64 that could assist with constructing a conceptual model of pathophysiology determined by the conditions of osteoporosis but ultimately resulting in the development of atherosclerotic calcifications and the reverse. We describe how estrogen deficiency leads to hyperlipidemia with inverse effects on osteoclasts and osteoblasts, consequent inflammation with oxidative stress, liberation of calcium and phosphate from resorbing bone with trapping of both minerals in the circulation as parathyroid secretion of PTH is no longer inhibited by one or two possible mechanisms and Klotho production decreases with inflammation and aging. Calcium and phosphate in the circulation are pro-inflammatory and promote dedifferentiation of vascular smooth muscle cells and replacement by osteogenic precursors. As well, no existing laboratory tests can determine how much circulating calcium and phosphate precipitate in blood vessels as serum determinations only tell us the current concentration of each mineral in solution. Finally, hypercalcemia will inhibit cholesterol catabolism perpetuating the accumulation of total and LDL cholesterol in the circulation. Atherosclerotic cardiovascular disease diminishes bone blood flow leading to further loss of bone. This model provides a basis for understanding how osteoporosis sets in motion pathologic processes resulting in atherosclerotic calcifications or the reverse. Future directions may include screening for abdominal aortic calcifications and fasting hyperlipidemia in osteoporosis patients, or obtaining bone densities in patients with cardiovascular disease. Earlier introduction of anti-resorptives may help prevent vascular calcifications in patients with osteoporosis or osteopenia.

NSS8

PSORIATIC DISEASE

L. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Psoriatic disease is a systemic autoinflammatory disease which affects both male and female patients. The disease affects both the musculoskeletal system causing psoriatic arthritis and the skin causing psoriasis. Psoriatic arthritis is a systemic autoinflammatory arthritis which affects the enthesis, i.e. the area where the tendons are attached to the bone. The disease mainly affects the spine and the central skeleton, however it may also cause peripheral arthritis. Psoriasis is an autoinflammatory and autoimmune disease which affects the skin causing multiple forms of skin lesions. Patients may display evidence of psoriasis first followed by involvement of the musculoskeletal system with the development of psoriatic arthritis. Some patients develop psoriatic arthritis whereas others may not develop psoriatic arthritis. In some cases psoriatic disease may develop first followed by the development of psoriasis. Psoriasis may take different forms and may also affect the nails causing nail psoriasis. In conclusion, psoriatic disease is a systemic autoinflammatory disease affecting both the musculoskeletal system and the skin.

NSS9

PSORIATIC DISEASE AND METABOLIC SYNDROME

Y. Dionyssiotis[1]

[1]Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Psoriatic disease may be accompanied by metabolic syndrome. Metabolic syndrome in the context of psoriatic disease is characterized by central or abdominal obesity, diabetes mellitus type 2, hyperlipidemia and arterial hypertension. The presence of metabolic syndrome is accompanied by an inflammatory phenotype as inflammatory cytokines are secreted which may be implicated in the systemic inflammation observed in psoriatic disease. The presence of metabolic syndrome needs specific treatment involving all metabolic manifestations. In particular, obesity should be prevented and treated. Diabetes mellitus type 2 should be treated. Hyperlipidemia should be effectively treated. Arterial hypertension should also be treated. The presence of metabolic

syndrome may be related with a severe and active profile of psoriatic arthritis. The presence of metabolic syndrome may be related to severe and active forms of psoriasis. In conclusion, metabolic syndrome may accompany psoriatic disease and may be related to active and severe forms of the disease.

NSS10
PSORIATIC DISEASE AND OBESITY

Y. Athanassiou[1], I. Kostoglou-Athanassiou[2]

[1]Department of Philology, Trinity College, Dublin, Ireland; [2]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Obesity may be present in patients with psoriatic disease in the context of metabolic syndrome. Obesity is related to severe and active disease in patients with psoriatic arthritis. Obesity is related to severe and active disease in patients with psoriasis. Therefore obesity needs active and effective management in patients with psoriatic disease. The application of GLP-1 receptor agonists may be applied successfully for the treatment of obesity. GLP-1 receptor agonists may induce weight loss and may improve the inflammatory phenotype of obesity and the inflammatory phenotype of psoriatic disease and improve the activity of the disease. All patients should be offered additional advice to lose weight by diet and physical activity.

NSS11
PSORIATIC DISEASE AND TREATMENT

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Psoriatic disease which includes psoriasis and psoriatic arthritis is an autoinflammatory disease. Nowadays many drugs are available for the treatment of both psoriasis and psoriatic arthritis. Conventional disease modifying antirheumatic drugs, biologic agents, biosimilars, Janus kinase inhibitors, interleukin-23 inhibitors and small molecules are available for the management of psoriatic disease. It is important to take into account the presenting features of the patients when choosing treatment. The presence of peripheral arthritis, axial disease, enthesitis, dactylitis, skin and nail disease should be considered when choosing medication for every patient. The presence of inflammatory bowel disease and uveitis should also be considered, as these manifestations are part of the spondyloarthritis spectrum. The metabolic manifestations of psoriatic disease should also be adequately managed.

NSS12
WHY PERIPROSTHETIC DXA NEEDS STANDARDIZATION: EVIDENCE, VARIABILITY, AND THE RAND/UCLA PROCESS

I. Etxebarria Foronda[1]

[1]Sociedad Española de Osteoporosis y Metabolismo Mineral (SEIOMM), Madrid, Spain

This opening session will frame the clinical and methodological problem that motivated the multisociety consensus. It will review evidence on periprosthetic bone mineral density (pBMD) changes after hip and knee arthroplasty, emphasizing that heterogeneous pDXA protocols—differences in positioning, scan coverage, acquisition modes, ROI definitions, and artifact handling—produce substantial measurement error and impede the development of robust, outcome-oriented datasets.

The session will then outline how this framework relates to the prior evidence-based joint position on perioperative bone optimization, which identified periprosthetic bone health as a modifiable factor but did not prescribe a detailed pDXA workflow.

The composition of the expert panel, governance procedures, and key steps of the RAND/UCLA Appropriateness Method—statement drafting, independent rating, discussion of disagreement, and second-round voting—will be described to make the consensus process transparent and open to scrutiny. Attendees will gain a clear understanding of what the framework does (standardizes measurement conditions and reporting) and what it deliberately does not do (propose outcome-validated diagnostic or therapeutic thresholds), thereby setting the stage for the subsequent technical and clinical sessions.

NSS13
FROM PIXELS TO PROTOCOLS: A PRACTICAL FRAMEWORK FOR HIGH-QUALITY PERIPROSTHETIC DXA

J. F. Torres-Naranjo[1]

[1]Asociación Mexicana de Metabolismo Óseo y Mineral (AMMOM), GUADALAJARA, Mexico

This session will translate the consensus document into a step-by-step "how-to" for performing periprosthetic DXA in hip and knee arthroplasty. It will cover: (1) quality assurance and site-specific precision assessment for periprosthetic ROIs; (2) joint-specific patient positioning and field-of-view rules; (3) the use of metal-removal or artifact-reduction modes and the importance of maintaining a continuous soft-tissue margin around the cortical bone to stabilize dual-energy decomposition; and (4) standardized, implant-anchored ROI templates for the hip (Gruen-adapted femoral zones and DeLee–Charnley acetabular zones) and knee (medial/lateral and metaphyseal/diaphyseal ROIs in PA and lateral projections). Special attention will be given to handling cement mantles, screws, plates, and revision constructs, where attempts at selective pixel-level exclusion often increase variability more than they reduce bias. The session will also explain the Minimum Dataset for Reporting (MDR), which captures key acquisition parameters, ROI schema, precision data, and technical limitations, ensuring that pDXA studies are auditable and comparable across time and centers.

Practical examples and annotated images will illustrate common pitfalls—such as geometric drift of ROIs, misclassification at the bone–implant interface, and truncation of soft-tissue margins—and show how the framework proposes to prevent and document them.

NSS14

INTERPRETING PERIPROSTHETIC BMD: PRECISION, LONGITUDINAL CHANGE, AND THERAPY-AWARE FLAGS

R. E. López-Cervantes[1]

[1]Federación Mexicana de Ortopedia y Traumatología (FEMECOT), Guadalajara, Mexico

Once acquisition and segmentation are standardized, the primary value of pDXA lies in quantifying temporal changes in periprosthetic BMD. This session will present the framework's recommendations for longitudinal analysis: establishing site-specific precision and the least significant change (LSC) for periprosthetic ROIs; defining realistic follow-up schedules (baseline within three months, 6 and 12 months, then annually); and replicating geometry and ROI templates across serial scans to avoid artifactual loss or gain.

The speakers will then discuss a therapy-aware interpretive model: how to interpret pBMD trajectories in untreated versus antiresorptive- or anabolic-treated patients; how to integrate central DXA, fracture history, and comorbidities; and how to use a consensus-based Green–Amber–Red flagging scheme that relies on ROI-specific LSC and spatial/temporal patterns rather than unvalidated cut-offs.

The limitations of pBMD as a surrogate biomarker and the absence of validated prognostic thresholds for aseptic loosening, periprosthetic fracture, or revision will be explicitly addressed. The session will conclude with practical examples showing how pDXA can support—not replace—clinical and radiographic assessment in perioperative bone-optimization pathways.

NSS15

THE FLS HISTORY IN ITALY – A DECADE OF ACTION

M. L. Brandi[1]

[1]President of the Observatory of Fragility Fractures Italy, Florence, Italy

Fragility fractures represent a major public health challenge in Italy, with 570'00 fractures in 2019, putting a severe burden on the healthcare system, as fragility fractures' costs are estimated at almost 10 billion euros annually[1].

To tackle the post-fracture care gap, Fracture Liaison Services have been introduced across the country over the past decade.

Since the first Fracture Liaison Service joined Capture the Fracture® in 2013, and following the establishment of the Fragility Fracture Observatory, the launch of the Fragility Fractures Guidelines and the national fracture registry, Professor Brandi will provide an overview of ten years of efforts related to the implementation of Fracture Liaison Services in Italy. In this review, she will highlight key milestones, outcomes, and future directions aimed at enhancing post-fracture care in the country.

Through the Italian experience, participants will get actionable insights and transferable lessons that can support effective and sustainable FLS development in their own settings.

[1] International Osteoporosis Foundation. Solutions for Fracture Prevention in Italy. 2022. Available at https://www.osteoporosis.foundation/sites/iofbonehealth/files/2023-01/2022_country_profile_it.pdf. (Accessed January 2026).

LEARNING FROM PEERS AND BUILDING A STRONG FLS COMMUNITY – THE JAPANESE EXPERIENCE

A. Suzuki[1]

[1]Fujita Health University School of Medicine, Tokyoake, Japan

In April 2022, the Japanese Ministry of Health, Labour and Welfare introduced a new reimbursement model, incentivising early surgery within 48 hours of injury and mandating comprehensive secondary fracture prevention[1]. This progressive policy has catalysed a transformation in fragility fracture care across Japan, accelerating the nationwide implementation of Fracture Liaison Services (FLS) and strengthening long-term osteoporosis management and patient outcomes.

In October 2024, Capture the Fracture® welcomed the 100th FLS from Japan into its global network. This milestone reflects Japan's strong national commitment to fracture prevention and osteoporosis care, supported by increased public recognition of FLS/OLS, a structured nationwide mentorship programme, and sustained engagement from multiple stakeholders. In close collaboration with national societies, including the Japan Osteoporosis Society, and with the active involvement of Capture the Fracture® mentors, the Japanese FLS/OLS community has been built around a shared focus on quality improvement and harmonisation of care across the country.

This peer-learning approach reached a further milestone in December 2025 with the organisation of the Capture the Fracture® Workshop. The highly collaborative atmosphere and strong engagement demonstrated the growing momentum to share best practices, align standards, and drive continuous improvement in FLS/OLS delivery nationwide.

Through the Japanese experience, participants will get more insights on how to build a strong collaborative community, working together to build sustainable and quality FLS/OLS.

A SET OF VARIABLES FOR THE ASSESSMENT OF FRAGILITY FRACTURE PATIENTS IN AN FLS ENVIRONMENT IN LATIN AMERICA (COUNTRY SPECIFIC DATASETS)

M. Calo[1], F. Paranhos[2], L. Tikle Vieira[3], R. De Figueiredo Radaeli[4], B.-H. Albergaria[5], C. Habib[6], F. Subies[6], M. Diehl[7], M. V. Barrachina[1]

[1]International Osteoporosis Foundation, Latin America Office, Buenos Aires, Argentina; [2]Hospital Universitário Clementino Fraga Filho – Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Policlínica Osvaldo Cruz, Porto Velho, Rondônia, Brazil; [4]Hospital Unimed, Bebedouro, São Paulo, Brazil; [5]Hospital das Clínicas, Universidade Federal do Espírito Santo, Vitória, Brazil; [6]Sanatorio Las Lomas, Buenos Aires, Argentina; [7]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Objective: To develop a questionnaire for the standardization of clinical, laboratory, and imaging data from patients with fractures treated at FLS (Fracture Liaison Services), with the aim of generating a homogeneous and comprehensive database. The resulting data will enable collaborative work and measuring individual and comparative effectiveness of secondary fracture prevention programmes among FLS included on the Map of Best Practices of the Capture the Fracture® (CTF) program by the International Osteoporosis Foundation (IOF) in Latin America.

Material and Methods: Two task forces were established, one in Argentina and one in Brazil, which worked independently to create a dataset with the most relevant and country-specific variables. To this purpose, experts considered national fracture registry and guidelines, epidemiological information on populations with fragility fractures, and effectiveness KPIs for secondary fracture prevention programs.

Results: The national datasets were defined considering relevant parameters for the performance of FLS at the different stages of identification, evaluation, treatment indication and follow up. Clinical, epidemiological, and demographic variables were included in the data collection, aiming at meeting CTF Best Practice Framework standards as well as feeding key performance indicators for measuring the effectiveness of FLS, while also driving quality improvement plans.

Conclusion: A country-specific database, which records relevant and comparable clinical data from FLS, is a tool that enables the analysis of key variables for the evaluation and improvement of the performance and sustainability of each service to the care of patients with osteoporosis and fragility fractures.

Acknowledgements: The authors would like to express their gratitude to the FLS Mentors from Argentina and Brazil for participating in dedicated country taskforces.

Disclosures: Authors report no conflict of interest.

NSS18

APPLYING BONE TURNOVER MARKERS IN DIALYSIS AND TRANSPLANTATION: CASE-BASED INSIGHTS

T. Nickolas[1]

[1]David C. and Betty Farrell Professor of Medicine Washington University School of Medicine, St. Louis, United States

The Kidney-Disease: Improving Global Outcomes (KDIGO) Controversies Conference in 2023 introduced the term chronic kidney disease associated osteoporosis (CKD-OP) to describe bone fragility in CKD. CKD-OP is a complex disorder of bone metabolism that is characterized by alterations in bone turnover and mineralization layered on top of impaired bone density and microarchitecture. Management of CKD-OP is based on the underlying turnover of bone, with agents that suppress turnover for high turnover bone and agents that enhance turnover for low turnover bone. While bone biopsy is the gold standard to assess turnover, its widespread use has significant limitations. The 2023 KDIGO Conference highlighted the role of circulating bone turnover markers to inform and guide management of CKD-OP with bone-targeting pharmacologic agents. In the clinic, circulating markers of bone turnover that are not cleared by the kidney, such as bone-specific alkaline phosphatase (BALP) and tartrate resistant acid phosphatase isoform 5b (TRACP5b) have reasonable accuracy for turnover abnormalities. We will use illustrative cases to demonstrate how turnover markers can be operationalized in the clinic to inform and guide management of CKD-OP.

NSS19

BALP, TRACP-5B AND IPINP: NEW REFERENCE MARKERS AND DIAGNOSTIC CUT-OFFS IN CKD

H. Skou Jørgensen[1,2,3]

[1]Department of Renal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [3]Department of Clinical Medicine, Aalborg University, Aarhus, Denmark

Bone turnover abnormalities are common in chronic kidney disease (CKD) and contribute to the high fracture risk in this patient population. The Kidney-Disease: Improving Global Outcomes (KDIGO) Controversies Conference in 2023 introduced the term CKD-associated osteoporosis to describe bone fragility in CKD and highlighted the role of biochemical markers of bone turnover in the clinical evaluation and management of this condition. The bone turnover markers recommended for use in post-menopausal osteoporosis (C-terminal telopeptides of type I collagen, β-CTX-I, and pro-collagen type I N-terminal propeptide, PINP) accumulate with kidney dysfunction and are difficult to interpret in the context of CKD. Consequently, a position paper by ESCEO, IOF, and IFCC recommended bone-specific alkaline phosphatase (BALP) and tartrate resistant acid phosphatase isoform 5b (TRACP5b) as reference biomarkers in CKD-associated osteoporosis. These non-kidney cleared biomarkers show good diagnostic accuracy for skeletal remodeling disturbances, as diagnosed by bone biopsy, in patients with CKD. Higher levels of biomarkers also associate with greater risk of bone loss and fractures, though their value for individual fracture risk prediction remains unclear.

A recent European consensus paper provides specific cutoffs of BALP, TRACP-5b and the intact form of PINP (iPINP) for identifying bone turnover abnormalities in CKD and suggests that these biomarkers may be instrumental in supporting clinical decision-making in CKD-associated osteoporosis. Future research should focus on the integration of these bone turnover markers with other diagnostic tools and the establishment of evidence-based treatment targets and protocols.

NSS20

THE GLOBAL LEADERSHIP INITIATIVE ON SARCOPENIA (GLIS): OBJECTIVES, STRUCTURE, AND ACHIEVEMENTS

A. Cruz Jentoft[1]

[1]Servicio de Geriatría. Hospital Universitario Ramón y Cajal (IRYCIS), Madrid, Spain

Over the past two decades, many international groups have developed definitions of sarcopenia that include reduced muscle function and low muscle mass. These definitions have advanced the field rapidly. However, the absence of a global consensus among the most widely used definitions impedes progress in the field, affecting both research and the integration of sarcopenia into routine clinical practice.

This lecture will explain how the Global Leadership Initiative in Sarcopenia (GLIS) was formed through the collaboration of the main former definition consensus groups. The initiative aims to create a comprehensive practical definition of sarcopenia that is widely accepted and adopted. The objectives of GLIS, the structure and composition of the groups involved in the initiative, and its main milestones, as well as the current activities and future projections will be described.

NSS21

HEALTH OUTCOMES OF SARCOPENIA: INSIGHTS FROM THE GLIS OUTCOME WORKING GROUP AND CLINICAL IMPLICATIONS

G. Duque[1]

[1]McGill University, Department of Medicine, Montreal, Canada

The Global Leadership Initiative in Sarcopenia (GLIS) was established to harmonize the definition and diagnostic criteria for sarcopenia into a single, internationally accepted classification. A central component of this effort is the Working Group (WG) on sarcopenia outcomes, which aims to identify clinically meaningful health outcomes that should be assessed once sarcopenia is diagnosed, as well as the optimal tools and cutoffs for their measurement. This abstract summarizes the key discussions, evidence base, and conclusions of the GLIS WG on outcomes, as previously reported.

The WG comprised 13 international experts representing multiple continents and disciplines. Its recommendations were informed by systematic reviews, meta-analyses, and high-quality cohort studies evaluating the association between sarcopenia and adverse health outcomes. The evidence demonstrates, with a high level of certainty, that sarcopenia is strongly associated with reduced quality of life, increased risk of falls and fractures, and higher all-cause mortality. Moderate-quality evidence also supports an association between sarcopenia and declines in instrumental activities of daily living (IADL), reflecting early functional impairment relevant to clinical practice.

In contrast, the available evidence was inconclusive regarding associations between sarcopenia and hospitalization, nursing home admission, mobility impairment, and reductions in basic activities of daily living (ADL). These gaps primarily reflect the limited number of longitudinal studies and heterogeneity in outcome definitions and assessment methods across existing research.

Overall, the GLIS WG highlights the urgent need for standardized outcome measures and well-designed longitudinal studies to better characterize the trajectory and clinical consequences of sarcopenia. These efforts are essential to support implementation of a unified sarcopenia definition and to improve risk stratification, clinical decision-making, and intervention development worldwide.

NSS22

UPDATED META-ANALYSIS ON THE HEALTH OUTCOMES OF SARCOPENIA

C. Beaudart[1]

[1]University of Namur, Namur, Belgium

In 2017, a landmark systematic review and meta-analysis provided the first comprehensive quantification of the association between sarcopenia and major health outcomes. Since then, the field has evolved considerably, with a rapid increase in high-quality longitudinal studies, broader geographic representation, longer follow-up periods, and the adoption of updated consensus definitions incorporating both muscle quantity and function. These developments warrant a timely and comprehensive update of the existing evidence.

This lecture will present results of the updated version of this systematic review and meta-analysis on the short-, middle-, and long-term clinical outcomes of sarcopenia in older adults, conducted using the same rigorous methodology as the original work, while integrating newly published studies and contemporary diagnostic criteria. The updated synthesis will examine a broad range of clinically relevant outcomes, including all-cause mortality, hospitalisation, falls, functional decline (activities of daily living and instrumental activities of daily living), cognitive decline, depressive symptoms, fractures, and institutionalisation.

By reassessing the strength and consistency of associations between sarcopenia and key health outcomes, this updated synthesis—aligned with the work of the GLIS Outcome Working Group—aims to refine the understanding of the clinical burden of sarcopenia and to support informed clinical decision-making as well as the development of effective prevention and management strategies.

NSS23

PRESENTATION 1: INTRODUCTION TO YOGA AND ITS RELEVANCE TO MUSCULOSKELETAL HEALTH

M. Chandran[1,2]

[1]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, Singapore, Singapore; [2]DUKE NUS Medical School, Singapore, Singapore

This presentation will offer a concise introduction to yoga, its origins, and its relevance to musculoskeletal health. Rooted in ancient Indian philosophy, yoga has evolved into a globally practised mind–body discipline that integrates postures (asanas), breathwork (pranayama), meditation, and mindfulness. Importantly, yoga is not a uniform intervention; its many styles, ranging from alignment-focused Iyengar yoga to dynamic Vinyasa flow, structured Ashtanga, traditional Hatha, and heat-based Bikram vary widely in intensity, biomechanical loading, and neuromuscular challenge. These differences have direct implications for outcomes such as balance, muscle strength, bone loading, and overall functional capacity, and must be considered when interpreting research on yoga's health effects.

The presentation will also briefly address the safety profile of yoga. While it is generally safe when practised with proper instruction, minor musculoskeletal discomforts are the most commonly reported adverse events. Rare incidents often related to loss of balance, excessive range of motion, or incorrect technique underscore the importance of supervision, especially for older adults or individuals with pre-existing conditions. Overall, this presentation will set the stage for the symposium by clarifying what yoga is, how its diverse forms interact with the musculoskeletal system, and what practitioners and clinicians should consider when integrating yoga into health-focused programmes.

NSS24

EFFECT OF YOGA ON BONE MINERAL METABOLISM

L. Nagendra[1]

[1]JSS Medical College, JSS Academy of Higher Education and Research, Mysore, Mysore, India

This presentation will provide a concise synthesis of current evidence examining how yoga influences two key determinants of musculoskeletal health: **bone mineral density (BMD)** and **balance**. Yoga incorporates weight-bearing postures, controlled transitions, axial loading, and proprioceptive challenge, all elements with plausible biomechanical relevance to bone strength and postural stability. However, published studies vary widely in yoga style, intensity, duration, and population studied, resulting in a heterogeneous evidence base. This session will review studies evaluating the impact of yoga on BMD across axial and appendicular sites, outline where findings converge or diverge, and identify the methodological factors that shape interpretation.

In parallel, the presentation will explore yoga's effect on balance, an equally important contributor to fracture risk. Drawing on studies that used standardized tools such as the Berg Balance Scale, Tinetti Assessment, single-leg stance, and dynamic posturography, the session will summarise the evidence for improvements in static and dynamic balance, fall risk, and neuromuscular control. Together, these discussions will provide an evidence-informed, balanced perspective on what yoga can realistically achieve for skeletal health and stability, highlight gaps in current research, and set the stage for future directions in studying mind–body interventions for osteoporosis prevention.

NSS25

EFFECT OF YOGA ON MUSCLE STRENGTH

P. Bajaj[1]

[1]National University Health System and Ministry of Health Holdings, Singapore, Singapore

This presentation will summarise current evidence on yoga's impact on **muscle strength**, a key determinant of bone health, functional capacity, and fall risk. Yoga incorporates a wide range of postures including seated, standing, weight-bearing, and isometric positions that engage major upper- and lower-limb muscle groups. While its benefits for balance and mobility have been increasingly explored, its effects on muscle strength have only recently been evaluated systematically. This session will draw on randomized controlled trials comparing yoga to both no-intervention controls and active comparators such as Pilates, Tai Chi, and core-strengthening programmes, providing an overview of how different yoga styles influence hand grip strength and lower-limb strength across diverse populations.

The presentation will also highlight methodological considerations such as variability in intervention duration, posture selection, intensity, and assessment techniques, all of which shape the interpretation of strength outcomes. Taken together, the available evidence suggests that yoga can serve as an effective mind body approach to improving muscle strength, with potential relevance for fall prevention and musculoskeletal resilience. This session will outline what is currently known, where evidence remains limited, and future priorities for defining yoga's role within strength- and stability-focused health programmes.

NSS26

ESTRADIOL THERAPY IN 2025: OPTIMIZING TYPE, DOSE, AND ROUTE FOR BONE PROTECTION ACROSS MENOPAUSAL STAGES

M. C. Osorio Wender[1,2,3,4]

[1]Full Professor of Obstetrics and Gynecology, Federal University of Rio Grande do Sul, Porto Alegre, Brazil; [2]Menopause and Contraception Clinic - Porto Alegre Clinical Hospital (HCPA), Porto Alegre, Brazil; [3]Head of Obstetrics & Gynecology Service at HCPA, Porto Alegre, Brazil; [4]President of Brazilian Federation of Obstetrics and Gynecology (FEBRASGO), Sao Paulo, Brazil

Background: Menopausal hormone therapy (MHT) prevents bone loss and reduces vertebral, non-vertebral, and hip fractures, with benefit modulated by timing since menopause, dose, regimen, and route of administration. Early postmenopause is the phase of maximal estrogen-deficiency bone loss, making regimen selection critical.

Methods: Narrative synthesis of randomized trials, large cohorts, and guideline statements evaluating estrogen alone or with progestogen,

transdermal vs oral routes, and dose-response across peri-, early-, and late-postmenopause, focusing on bone mineral density (BMD), fractures, and safety.

Results: MHT lowers fracture risk during use (odds ratio [OR] ~0.75–0.76 for current users) with attenuation after discontinuation; risk may transiently rebound before converging below never-users beyond 10 years off-therapy. Anti-fracture efficacy is robust even in women unselected for low BMD, greatest when initiated before age 60 or within 10 years since menopause. Dose: estrogen effects are dose-dependent; low and ultra-low doses still preserve or increase BMD, particularly in women with very low endogenous estradiol. Route: transdermal and oral routes yield similar BMD gains, but oral therapy confers higher venous thromboembolism (VTE) risk; transdermal minimizes hepatic effects. Conventional-dose combined estrogen-progestogen lowers spine and hip fractures; low-dose effects on fractures may be weaker, though BMD is maintained. Early menopause/POI: MHT is first-line for skeletal preservation; earlier age at menopause independently heightens fracture risk, underscoring timely initiation. After stopping MHT, sequential antiresorptive (e.g., alendronate, raloxifene) can sustain or augment BMD.

Conclusions: For bone protection, initiate MHT in symptomatic women <60 years or within 10 years of menopause, using the lowest effective estrogen dose; prefer the transdermal route when VTE/metabolic risk is a concern, and ensure appropriate progestogen if uterus intact. Plan exit strategies with DXA reassessment and timely transition to antiresorptive drugs to mitigate post-cessation bone loss and fracture rebound.

NSS27

BEYOND ENDOMETRIAL SAFETY: DO DIFFERENT PROGESTOGENS CHANGE LONG-TERM SKELETAL AND METABOLIC RISK?

J. Kulak Junior[1,2,3]

[1]Associate Professor of Obstetrics and Gynecology, Federal University of Paraná (UFPR), Curitiba, Brazil; [2]Member of National Committee on Menopause of FEBRASGO, Sao Paulo, Brazil; [3]General Secretary of the Brazilian Menopause Society – SOBRAC, Sao Paulo, Brazil

Background: In menopausal hormone therapy (MHT), progestogens are essential for endometrial protection, but their skeletal and metabolic effects may differ by molecule and androgenic/glucocorticoid activity, route, and dose. Micronized progesterone and dydrogesterone appear metabolically neutral compared with several synthetic progestins, yet long-term outcomes remain incompletely defined.

Methods: Narrative synthesis of randomized trials, observational cohorts, and systematic reviews evaluating bone mineral density (BMD), fractures, lipids, insulin resistance, and venous thromboembolism (VTE) across progestogens used with estrogen, plus data from progestin-only contraceptives informing class effects.

Results: Progestin identity matters. Medroxyprogesterone acetate (MPA) can blunt estrogen's favorable lipid effects and lower HDL cholesterol, whereas micronized progesterone shows smaller attenuation and neutral cardiometabolic impact in short-term trials. With transdermal estrogen, micronized progesterone and norpregnanes (e.g., dydrogesterone) are linked to lower VTE risk than some synthetic progestins. Bone: In MHT, norethisterone (NET) combined with estrogen increased distal radius BMD by 2.3% over 2 years and reduced nonvertebral fractures (RR 0.14, 95% CI 0.02–0.93), outperforming estrogen+MPA (BMD +1.6%; nonsignificant fracture reduction) in one trial, suggesting differences tied to glucocorticoid activity. Progestin-only depot MPA (DMPA) decreases BMD during use, with partial to full recovery after discontinuation; fracture risk signals are inconsistent but may rise with prolonged exposure (OR up to 3.04 in heavy users <30 years). Combined oralcontraceptives generally show neutral BMD effects although fracture data are limited.

Conclusions: Beyond endometrial safety, progestogens differ in skeletal and metabolic profiles. Micronized progesterone/dydrogesterone are generally cardiometabolically neutral with transdermal estrogen and may minimize VTE risk, while MPA and more androgenic agents variably attenuate lipid benefits and lower HDL. For bone, choice may influence BMD and fractures when combined with estrogen, and progestin-only DMPA warrants caution in prolonged use. Long-term fracture and cardiometabolic outcome trials omparing progestogens are a key unmet need.

NSS28

ANDROGENS AND THE FEMALE MUSCULOSKELETAL SYSTEM: EVIDENCE, GAPS, AND THE FUTURE OF THERAPY

A. Orcesi Pedro[1,2,3,4,5,6]

[1]Professor of post-graduate Course of Department of Obstetrics and Gynecology - Medical School from University of Campinas - UNICAMP, Campinas, Brazil; [2]Associate gynecologist of the Climacteric Outpatient Clinic at Women´s Health University Hospital (CAISM-UNICAMP), Campinas, Brazil; [3]Past president and current Vice-President of National Committee on Osteoporosis of FEBRASGO, Sao Paulo, Brazil; [4]Member of the Regional Advisory Board of International Osteoporosis Foundation – Latin America, Nyon, Switzerland; [5]Member of Committee of Scientific Advisor of International Osteoporosis Foundation, Nyon, Switzerland; [6]Menopause Society Certified Practitioner, Pepper Pike, Ohio, United States

Background: The role of androgens in female musculoskeletal health remains controversial. Androgens act on bone and muscle in women via androgen receptors and through aromatization to estrogens, influencing osteoblast differentiation, bone remodeling, and muscle mass, yet clinical applications remain limited and heterogeneous Over the past decade, increasing attention has been given to testosterone therapy in postmenopausal women; however, its efficacy for bone and muscle outcomes is uncertain, particularly when compared with established therapies such as menopausal hormone therapy (MHT).

Objective: To critically review current evidence regarding the effects of testosterone and other androgens on bone mineral density (BMD), muscle strength, and fracture risk in postmenopausal women, highlighting knowledge gaps and implications for future therapeutic strategies.

Methods: Narrative synthesis of systematic reviews, meta-analyses, randomized controlled trials (RCTs), observational cohort studies, Mendelian randomization analyses, and international clinical guidelines published over the last 10 years.

Results: High-quality evidence consistently demonstrates that systemic testosterone administered at physiological doses to postmenopausal

womendoes not confer reliable benefits on bone mineral density (BMD), muscle mass, muscle strength, or fracture prevention. Meta-analyses and global consensus statements report no significant effects on lumbar spine, total hip, or femoral neck BMD over 12 months, nor on lean mass or physical performance, while mild androgenic adverse effects are more frequent. Consequently, the only evidence-based indication for testosterone therapy in women remains hypoactive sexual desire disorder (HSDD). In contrast, MHT with estrogen, with or without progestogen, has robust evidence supporting increases in BMD and significant reductions in total, hip, and major osteoporotic fractures while in use. Observational and genetic studies suggest that endogenous androgen balance may influence skeletal health: higher sex hormone–binding globulin (SHBG) levels are consistently associated with increased fracture risk, whereas higher bioavailable testosterone and DHEAS appear to correlate with higher BMD and lower peripheral fracture risk. However, these associations do not establish causality or justify androgen supplementation for skeletal indications. Resistance and high-impact exercise remain an effective non-pharmacological intervention for improving muscle strength and modestly increasing BMD. Key gaps include optimal dosing, patient selection, fracture outcomes, and comparative safety versus estrogen-based therapy. Future directions include targeted trials of physiologic androgen replacement and biomarker-driven personalization to clarify benefit–risk and improve musculoskeletal health in women.

Conclusion: Current evidence does not support the use of systemic testosterone for musculoskeletal benefits in postmenopausal women. Adequately powered RCTs demonstrating fracture or BMD benefit are lacking. MHT, targeted anti-osteoporotic therapies, and structured exercise programs remain the cornerstone strategies for bone and muscle health in this population. Testosterone therapy should be restricted to HSDD, using transdermal formulations at physiological doses, with careful monitoring and acknowledgment of long-term safety uncertainties.

NSS29

HIGH PREVALENCE OF OSTEOPOROSIS IN AUTOIMMUNE AND INFLAMMATORY DISEASES

E. Bischoff[1], F. Bischoff[2], N. Kirilov[3], S. Vladeva[4]

[1]Rheumazentrum Ruhrgebiet, Herne, Ruhr University, Bochum, Germany; [2]Rheumatology practice Stara Zagora, Stara Zagora, Bulgaria; [3]Department of Orthopedic and Traumatology, MBAL Dr. Georgi Stranski, Medical University of Pleven, Pleven, Bulgaria; [4]Department of Health Care, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria

Background Osteoporosis is a frequent yet often under-recognized comorbidity in autoimmune and inflammatory diseases. Chronic systemic inflammation, immune-mediated bone resorption, prolonged exposure to glucocorticoids, reduced physical activity and disease-related disability all contribute to impaired bone strength and increased fracture risk. Despite this, osteoporosis screening and fracture prevention strategies remain inconsistently implemented in routine care.

Aim To highlight the prevalence, pathophysiological mechanisms and clinical relevance of osteoporosis in autoimmune and inflammatory diseases, emphasising the need for systematic bone health assessment in these populations.

Methods A narrative review of epidemiological studies, pathophysiological research and international guidelines addressing bone loss and fracture risk in inflammatory and autoimmune conditions.

Results Evidence consistently shows increased rates of low bone mass and fractures in autoimmune and inflammatory diseases. Chronic inflammation stimulates osteoclast activity and suppresses osteoblast function through cytokines such as TNF-α and IL-6, leading to microarchitectural deterioration. Long-term corticosteroid therapy further increases fracture risk even when BMD is not severely reduced. In ankylosing spondylitis (AS), spinal BMD can be falsely elevated on DXA due to ossification. REMS, a non-ionizing ultrasound-based technique, demonstrates excellent precision, allowing detection of smaller BMD changes over shorter intervals and offering potential advantages, particularly in patients with artifacts such as degenerative changes or spinal alterations in AS. Furthermore, REMS-derived Fragility Score may better predict incident osteoporotic fractures than T-scores from either REMS or DXA.

Conclusion Osteoporosis is highly prevalent in autoimmune and inflammatory diseases because of the combined effects of chronic inflammation and corticosteroid therapy, yet current diagnostic approaches frequently fail to detect early deterioration in bone quality. REMS may help bridge this diagnostic gap and support earlier intervention, although further prospective studies are required.

Key words: osteoporosis, prevalence, autoimmune, inflammatory disases

NSS30

CLINICAL CHALLENGES AND DIAGNOSTIC GAPS IN OSTEOPOROSIS ASSESSMENT: THE ROLE OF REMS TECHNOLOGY

M. Hristova[1], N. Kirilov[2], S. Vladeva[3], E. Bischoff[4]

[1]Trakia University, Stara Zagora, Bulgaria; [2]Department of Orthopedic and Traumatology, MBAL Dr. Georgi Stranski, Medical University of Pleven, Pleven, Bulgaria; [3]Department of Health Care, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria; [4]Rheumazentrum Ruhrgebiet, Herne, Ruhr University, Bochum, Germany

Background Conventional osteoporosis diagnostics, particularly dual-energy X-ray absorptiometry (DXA), may be limited in patients with inflammatory diseases and in special clinical settings such as pregnancy. Positioning difficulties, skeletal deformities, artefacts, cumulative radiation exposure and safety concerns can compromise diagnostic accuracy and feasibility, leading to underdiagnosis of bone fragility.

Aim To discuss current diagnostic gaps in osteoporosis assessment in inflammatory diseases and pregnancy and to explore the potential role of Radiofrequency Echographic Multi-Spectrometry (REMS) as an alternative imaging approach.

Methods Review of clinical studies evaluating feasibility, diagnostic performance and clinical applicability of REMS technology compared with standard densitometry in inflammatory diseases and pregnancy.

Results Evidence suggests that REMS, a non-ionising ultrasound-based technique, allows axial skeletal assessment without radiation exposure and with fewer positioning constraints. Preliminary data indicate good agreement with DXA and improved feasibility in patients with spinal damage, disability or during pregnancy, where ionising techniques are

restricted. REMS may therefore address important diagnostic gaps in challenging clinical scenarios. REMS especially attractive in clinical situations where ionising techniques are restricted or contraindicated, such as during pregnancy or in patients requiring repeated assessments. By improving accessibility and safety while maintaining diagnostic performance, REMS has the potential to address key diagnostic gaps and facilitate earlier, more inclusive bone health evaluation in complex and vulnerable patient populations.

Conclusion Diagnostic limitations contribute significantly to the under-recognition of osteoporosis in inflammatory diseases and pregnancy. REMS technology represents a promising, patient-centred tool that may enhance accessibility, safety and accuracy of bone health assessment, although further validation and long-term outcome data are required.

Key words: bone assessment, clinical challenges, diagnostic gaps

NSS31

PATHOPHYSIOLOGY, RISK ASSESSMENT CHALLENGES, AND NON-PHARMACOLOGICAL STRATEGIES IN DIABETIC BONE FRAGILITY

T. Erdogan[1,2]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye; [2]Istanbul Musculoskeletal Health Consortium, Istanbul, Türkiye

Background: Older adults with both type 1 (T1D) and type 2 diabetes (T2D) have a substantially increased risk of fragility fractures, contributing significantly to morbidity and mortality. Importantly, the mechanisms underlying skeletal fragility differ between diabetes types.

Objectives: To summarize the distinct pathophysiological mechanisms of diabetic bone fragility, highlight limitations of current fracture risk assessment tools, and discuss evidence-based non-pharmacological management strategies in older adults with diabetes.

Content: In T1D, insulin deficiency leads to impaired osteoblast function and reduced bone mineral density (BMD), primarily affecting bone quantity. In contrast, T2D is characterized by the "diabetic bone paradox," where BMD is often normal or elevated, yet fracture risk is increased due to compromised bone quality. This impairment results from altered microarchitecture, accumulation of advanced glycation end products, low bone turnover, chronic inflammation, and oxidative stress. Standard fracture risk assessment tools, including DXA-derived BMD and FRAX, frequently underestimate fracture risk in diabetes—particularly in T2D—because they inadequately capture bone quality and fall risk. Incorporation of diabetes-specific factors (disease duration, glycemic control, microvascular complications), alongside assessment tools such as trabecular bone score and FRAX-based adjustments, is essential. Non-pharmacological strategies are fundamental and include optimization of nutrition (adequate calcium, vitamin D, and protein intake), individualized exercise programs combining resistance and balance training, and comprehensive fall prevention. Fall risk is especially high in older adults with diabetes due to hypoglycemia, neuropathy, visual impairment, sarcopenia, and polypharmacy.

Conclusions: Diabetic bone fragility represents a complex, multifactorial condition requiring a tailored approach beyond conventional osteoporosis paradigms. Improved risk stratification and robust non-pharmacological interventions are central to effective fracture prevention in older adults with diabetes.

NSS32

SKELETAL EFFECTS OF ANTI-DIABETIC DRUGS AND OSTEOPOROSIS MANAGEMENT IN PATIENTS WITH DIABETES

S. Ozkok[1,2]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Türkiye; [2]Istanbul Musculoskeletal Health Consortium, Istanbul, Türkiye

Background: Management of bone fragility in diabetes requires balancing optimal glycemic control with preservation of skeletal health and minimization of fall risk.

Objectives: To review the skeletal effects of commonly used anti-diabetic medications and outline evidence-based osteoporosis treatment strategies in older adults with diabetes.

Content: Individualized glycemic targets are critical in older adults, particularly those who are frail, where relaxed HbA1c goals (approximately 8.0–8.5%) may reduce hypoglycemia-related falls without substantially increasing hyperglycemia-associated bone damage. Anti-diabetic drug selection should prioritize agents with neutral or potentially beneficial skeletal profiles and low hypoglycemia risk, including metformin, DPP-4 inhibitors, GLP-1 receptor agonists, and SGLT2 inhibitors. Thiazolidinediones should be avoided due to their well-established association with bone loss and fractures through diversion of mesenchymal stem cell differentiation toward adipogenesis. Insulin use is consistently associated with increased fracture risk, largely driven by hypoglycemia and disease severity rather than direct skeletal toxicity. When osteoporosis pharmacotherapy is indicated, available evidence—largely from post-hoc and observational analyses—suggests that antiresorptive agents such as bisphosphonates and denosumab are effective in patients with diabetes. Renal function, risk of hypocalcemia, and rebound fractures after denosumab discontinuation must be carefully considered. Anabolic therapies (teriparatide and abaloparatide) are particularly attractive in T2D due to its low bone turnover state. Romosozumab provides potent gains in bone mineral density but requires cautious use in patients with high cardiovascular risk.

Conclusions: Optimal management of diabetic bone fragility demands integrated, goal-directed therapy that accounts for glycemic safety, skeletal effects of glucose-lowering drugs, comorbidities, and overall fracture risk. Individualized treatment selection is essential to improve outcomes in this high-risk population.

NSS33

THE AI LANDSCAPE IN BONE HEALTH 2026: FROM MULTIMODAL MODELS TO CLINICAL AGENTS

N. Fuggle[1]

[1]Associate Professor, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Artificial intelligence (AI) is increasingly embedded within clinical practice and advances in computer vision and large language models have moved the field of clinical AI from experimental exploration toward tools that are beginning to demonstrate real-world clinical utility. In bone health and osteoporosis care, these developments offer the prospect of robust opportunistic screening, and potential support for complex clinical decision-making.

Despite this promise, the translation of AI into routine osteoporosis practice presents challenges. This presentation examines the methodology behind current deployment of AI in osteoporosis including ambient voice technology, computer vision tools and clinical decision-support systems. We will highlighting the key issues of generalisability, bias, explainability, clinical validation and where they sit in clinical workflows.

Attendees will gain a balanced understanding of how these technologies can be responsibly evaluated and adopted, with an emphasis on safety, transparency, and alignment with clinical priorities.

It will not be long before the majority of consultations incorporate the use of AI in some form. It is vital that we, as clinicians and academics, understand these tools and the way they influence the care of our patients.

Disclosures: *NF consults for DocHQ, an AI Physio company.*

NSS34

CURRENT ML MODELS FOR PREDICTING FRACTURE RISK – DO THEY MEET THE CLINICAL NEED AND IF NOT THEN WHAT ARE THE NEXT STEPS?

B. Abrahamsen[1]

[1]Professor, University of Southern Denmark, Odense, Denmark

This talk will discuss machine learning models for fracture prediction, synthesising evidence on model performance, calibration, transparency, and clinical readiness. We will place these models in context relative to established tools and will highlight methodological challenges that must be addressed in the view of the clinician before widespread deployment:

The last decade has seen publication of a number of ML models for prediction of fracture risk, including models with AUCs of 0.8 to 0.9 for osteoporotic fractures or hip fracture specifically.: Most studies aimed at covering the whole population over a certain age, while others focus on specific groups or circumstances. The time perspective for outcomes varies with some models being focused on imminent risk and others on longer term risk. For most models, extensive validation in other countries or ethnic groups is available only to a small extent or not at all. Hence, performance as presented reflects a best-case scenario. Accurate calibration to other populations is essential and clinicians will likely find models easier to interpret and implement if at least the main features can be inspected. Data imbalance is a technical challenge where severe class imbalance can bias models towards the majority class i.e. person who do not sustain a fracture and this has been approached by different mitigation steps in the models.

As clinicians, we may have failed to accurately stipulate acceptable sensitivity and specificity goals. Moreover, these will vary depending on the organisation of the clinical path, e.g. directing patients to DXA or directing patients directly to treatment without DXA. Directions for future research to best meet the clinical need will be discussed.

Disclosures*: BA contributed to the clinical development of the Bonebot/ Flamingo tool for automated detection of vertebral fractures and has in the past held research grants and consulting from UCB, Novartis, Amgen, Pharmacosmos and Kyowa-Kirin. He does not receive royalties and has no patents*

NSS35

ENSURING SAFE, EQUITABLE, AND REGULATED AI IN OSTEOPOROSIS CARE

T. Ankeet[1]

[1]Hardian Health, Haywards Heath, United Kingdom

Artificial intelligence (AI) has the potential to transform osteoporosis care by improving early identification of at-risk patients, streamlining clinical pathways, and enhancing the efficiency of healthcare delivery, with possible downstream cost benefits. However, these benefits can only be realised if AI tools deployed in clinical practice are safe, effective, and cybersecure.

Regulation plays a critical role in ensuring that AI-based systems meet these requirements. This presentation will provide an overview of the core regulatory frameworks that apply to medical devices, including software and AI-enabled technologies. It will explain how these frameworks are designed to assure safety, performance, and ultimately deliver clinical benefit. We will touch on core components of the regulatory process including clinical evaluation, risk management, and post-market surveillance. In parallel, the talk will outline what healthcare providers and purchasers should consider when procuring AI tools for osteoporosis care.

Finally, we will also address AI-specific challenges that have particular regulatory relevance, including model retraining, risks of bias, and performance drift following deployment. To conclude, we will examine how regulatory frameworks are evolving to better accommodate AI-based medical devices, highlighting areas of ongoing development as well as unresolved grey-areas that continue to present challenges for developers, regulators, and adopters.

NSS36

KIDNEY HEALTH IN HYPOPARATHYROIDISM

J.-P. Bertocchio[1]

[1]Nephrology Department, Pitie'-Salpetriere Hospital, Paris, France

Parathyroid hormone (PTH) is a key regulator of kidney function and the lack of the hormone, typical in hypoparathyroid conditions, causes excessive secretion of calcium in the urines.

Kidney complications are frequent in hypoparathyroidism (HypoPT) with 36-40% of patients experiencing hypercalciuria and 10-31% experiencing nephrocalcinosis or nephrolithiasis. The risk of chronic kidney disease (CKD) is generally reported to be 2-3 times greater than controls in patients with surgical HypoPT. These problems can be the consequence of PTH deficiency combined with high-dose calcium and active vitamin D treatment.

The treatment with PTH peptides has the potential to solve the problem. In controlled clinical trials neither PTH 1-34 nor PTH 1-84 appeared to be active in achieving an effective decrease in calciuria levels, but the long-acting Palopegteriparatide showed a powerful effect in controlling urinary calcium levels both in normocalciuric and hypercalciuric patients. Potential mechanisms playing a role in the effects are both calcium reabsorption at the tubular level and the increased glomerular filtration rate through an effective renal plasma flow.

Also the calcium sensing receptor antagonists Encaleret appears to be active in reducing urinary calcium levels in hypercalciuric patients affected by the congenital autosomal dominant hypoparathyroidism type 1 (ADH1). Similarly the PTH receptor selective agonist Eneboparatide appears effective in the control of calciuria in hypoparathyroid patients.

Normalization of kidney function is one of the main chronic complications of HypoPT, representing a major target in the future development of drugs for hypoparathyroidism. In this presentation the physiopathology of PTH regulation of kidney function will be presented and discussed in depth, with a critical discussion on how the new pharmacological agents developed for hypoparathyroidism will contribute to the solution of the problem.

NSS37

BONE HEALTH IN HYPOPARATHYROIDISM

A. Khan[1]

[1]McMaster University Divisions Endocrinology and Metabolism and Geriatrics, Calcium Disorders Clinic, Hamilton, Ontario, Canada

Parathyroid hormone (PTH) is a key regulator of bone remodeling and the insufficient or lack of secretion of the hormone is accompanied by a reduced bone turnover.

Decreased biomarkers of both bone formation and resorption have been reported in hypoparathyroidism (HypoPT), with variable values of bone mineral density (BMD) depending on sex and age. Abnormalities in bone microarchitecture have also been described in hypoparathyroid patients. The bone tissue is supposed to exhibit a high stifness and a reduced elasticity with increased microcracks and fractures. An increased fracture risk, mainly at the vertebral level, has been reported in hypoparathyroid patients.

Chronic treatment with PTH peptides appears to improve the bone structure in HypoPT, while increasing bone turnover. The question still pending is regarding the long-term effects of these therapies on bone turnover and fracture risk, mostly in hypoparathyroid patients with osteopenia and osteoporosis.

The recent controlled clinical trials with different active molecules appear to do not negatively affect bone health in hypoparathyroid patients. However, long-term studies are missing and prospective evaluation of the treated populations are certainly needed.

In this presentation the physiopathological role of PTH in bone remodeling will be presented and the results obtained with PTH peptides, Encaleret and Eneboparatide in controlled clinical studies in hypoparathyroid patients will be critically discussed with a particular attention to the need of collecting clinical data in the future real life analyses.

NSS38

HIP BIOMECHANICS AND FRACTURE RISK: BEYOND BONE DENSITY

A. Kurth[1]

[1]Orthopaedic and Trauma Surgeon, Frankfurt/Main, Germany

Osteoporotic hip fractures are a leading cause of morbidity and mortality in older adults, with fracture risk determined not only by bone mineral density but also by the biomechanical characteristics of the hip. Hip biomechanics play a critical role in load transmission, energy absorption, and structural resistance to fracture during daily activities and falls. Geometric parameters of the proximal femur, including femoral neck length, neck–shaft angle, cortical thickness, and hip axis length, influence stress distribution and bending moments acting on osteoporotic bone. Alterations in these parameters, often exacerbated by age-related bone loss and changes in gait and muscle function, increase susceptibility to fracture under low-energy trauma. In addition, fall mechanics, impact direction, and the ability of surrounding soft tissues to dissipate energy further modulate fracture risk. Emerging biomechanical models and finite element analyses demonstrate that local stress concentrations in the femoral neck and intertrochanteric region may better predict fracture risk than bone mineral density alone. Understanding the biomechanical determinants of hip fragility provides a more comprehensive framework for fracture risk assessment, personalized surgical planning, implant design, and local bone-strengthening interventions.

NSS39

MANAGEMENT OF HIP FRACTURES – THE GERMAN APPROACH

K. Michalke[1]

[1]Orthopaedic and Trauma Surgeon, Nettethal, Germany

Proximal femoral fractures caused by osteoporosis represent a major clinical and socioeconomic challenge in aging populations. Optimal management requires timely surgical intervention, as **„Time to Surgery** is considered a sensitive quality indicator of the treatment process, reflecting patient-related factors, organizational structures, and interdisciplinary coordination within healthcare systems. Delays to surgery are associated with increased morbidity, mortality, and reduced

functional outcomes. A wait time of 24 hours may represent a threshold defining higher risk. In response to these concerns, a special need for action was identified by the German Gemeinsamer Bundesausschuss (G-BA), emphasizing the importance of standardized care pathways and quality assurance measures for hip fracture management. Due to legal requirements, sugery of hip fracture has be performed within 24 hours after the fracture occured. Evidence-based surgical treatment options for proximal osteoporotic femoral fractures include internal fixation techniques, such as intramedullary nailing and screw-based systems, as well as joint replacement procedures, particularly hemiarthroplasty and total hip arthroplasty, depending on fracture pattern, bone quality, and patient characteristics. Current evidence supports procedure selection tailored to fracture stability, biological age, and functional demands, with early surgery as a central determinant of outcome quality. Implementing guideline-conform surgical strategies combined with optimized perioperative logistics is essential to improve patient outcomes and meet established quality indicators in the care of osteoporotic proximal femoral fractures.

NSS40

LOCAL BONE AUGMENTATION TO PREVENT HIP FRACTURES

U. Maus[1]

[1]Orthopaedic and Trauma Surgeon, Düsseldorf, Germany

Osteoporotic fragility fractures have emerged as a significant and unresolved burden on healthcare systems worldwide. While pharmacological therapies are known to lower the risk of such fractures, important gaps persist in clinical management, particularly for individuals facing an immediate risk of hip fracture, due to the delayed onset of therapeutic benefit after treatment initiation. This limitation highlights the need for alternative strategies, including localized hip interventions capable of providing rapid mechanical reinforcement. The presentation aims to outline a procedure that improves the biomechanical strength of the proximal femur and stimulates new bone formation. The local osteo-enhancement procedure (LOEP) is a minimally invasive surgical technique designed to treat bone voids in the proximal femur, arising from osteoporotic changes of the bone. Following preparation of voids within the femoral neck and intertrochanteric areas, a resorbable, triphasic, calcium-based implant material, is introduced into the target site. Clinical investigations have shown predictable resorption of the implant, simultaneous replacement with native bone, and a significant and sustained increase in areal bone mineral density (aBMD). Overall, completed clinical studies indicate that the procedure has an acceptable safety profile and may contribute to a reduced risk of hip fragility fractures.

NSS41

UPDATE IN DEGENERATIVE JOINT DISEASE OF HAND, OSTEOARTHRITIC HAND

F. Dincer[1,2,3,4]

[1]Professor of Physical and Rehabilitation Medicine, Ankara, Türkiye; [2]President Turkish Society of Rehabilitation Medicine, Ankara, Türkiye; [3]ESCEO Scientific Advisory Board Member, Ankara, Türkiye; [4]ESPRM Chair Musculoskeletal Disorders, Ankara, Türkiye

Introduction

Hand osteoarthritis (HOA) is a prevalent degenerative musculoskeletal condition that primarily affects the small joints of the hands and wrists, leading to pain, stiffness, decreased grip strength, functional limitations in daily activities, and reduced quality of life. HOA is more common with advancing age and disproportionately affects women in older age groups, with radiographic changes seen in many individuals but symptomatic disease in a smaller proportion of the population.

Objective

This presentation aims to synthesize recent evidence from systematic literature on updates in non-pharmacological and pharmacological approaches to the management of HOA, incorporating new guidelines, systematic reviews, and clinical trials published over the last years. Emphasis is placed on integrating evidence-based recommendations with patient-centric perspectives.

Methods

We conducted a structured literature search primarily in the PubMed database and online repositories of clinical guidelines, focusing on English-language publications from the last years that provide updated recommendations or clinical evaluations in HOA care. Core sources included updated management guidelines such as the 2019 ACR/Arthritis Foundation recommendations and the 2022 ESCEO expert working group report, which align US evidence-based practice with a European approach that emphasizes patient preferences.

Earlier foundational guidelines, including the EULAR recommendations for HOA management and EULAR diagnostic criteria (2009), were referenced where current updates did not alter the original evidence base or recommendations. The aim was to integrate these sources to provide comprehensive, evidence-based guidance on optimal HOA management strategies.

Results (Updated with New Literature)

Available guidelines and consensus recommendations on Hand OA recommend exercises as part of current best practice for Hand OA management. Also, the combination of splints for thumb base OA, orthoses and exercise regimens reduce pain and improve functionality in the short and long term and prevent/correct lateral angulation and flexion deformity. There is strong evidence to support the recommendation of strengthening, stretching, and joint mobility exercises for the management of hand OA. These recommended exercises, however, lacked specific details regarding the type and dosage (frequency, intensity and time) for optimal uptake, which therefore need further establishment through research.

Additional recent evidence further clarifies treatment effects:

- A recent 2024 systematic review on the efficacy and safety of

non-pharmacological, pharmacological and surgical treatments confirms that hand exercises and thumb orthoses have moderate- to low-certainty evidence for improving pain and function, while assistive devices contribute to moderate long-term functional improvement. It also highlights a continuing lack of strong evidence for interventions that significantly improve grip strength and emphasizes the need for better-powered trials and OA subtyping.

• A qualitative study on task-shifting between rheumatologists and occupational therapists shows that interprofessional care models are evolving, with occupational therapists taking on expanded roles in clinical assessment and functional management of hand OA, reflecting changes in care delivery and potential impacts on rehabilitation pathways.

• A 2025 systematic review of the prognosis of pain and function in individuals with hand and thumb base OA reveals that, over a 10-year period, hand function and grip strength tend to deteriorate moderately, while average pain changes are smaller; baseline pain severity and comorbidities such as diabetes may influence symptomatic trajectories.

• The narrative perspective "A firm grip on hand OA: 20 years of progress and prospects" underscores how the field has matured over the past two decades, recognizing phenotypic heterogeneity, standardized outcome measures, and sustained challenges in developing truly disease-modifying therapies despite progress in understanding inflammatory and mechanical contributors to pathology.

• A comprehensive review of molecular mechanisms, randomized controlled trials, and future targeted treatment strategies highlights emerging biological insights—such as joint-specific inflammatory pathways, genetic and epigenetic factors, and the gut–joint axis—and notes that while several targeted pharmacologic agents (e.g., TNF/IL-6 inhibitors) show limited clinical success, this work provides a framework for future precision therapeutics.

Hand exercise recommendations for Hand OA management (updated):

1. Exercises to improve hand function and muscle strength, and to reduce hand pain—such as strengthening, stretching, and joint mobility exercises—should be considered for every patient with hand OA. These exercises can be prescribed as home-based or supervised weekly exercises over several weeks. Grade of recommendation (A) — Strength of recommendation (Strong)

2. Hand strengthening exercises should be considered for hand OA management due to their clinically beneficial effect on hand pain and grip force. Grade of recommendation (B) — Strength of recommendation (Strong)

3. Exercise in combination with orthosis improves hand pain and functionality in both the short and long term. Grade of recommendation (B) — Strength of recommendation (Strong)

4. Education regarding an exercise regimen including muscle strengthening and range-of-motion exercises, in combination with joint protection techniques, should be recommended for all patients with HOA. Grade of recommendation (GCP / Good Clinical Practice based on expert opinion) — Strength of recommendation (Weak)

5. Advise people with hand OA to exercise as a core treatment irrespective of age, comorbidity, pain severity, or disability. Exercise should include local muscle strengthening and general aerobic fitness. Grade of recommendation (GCP / Good Clinical Practice based on expert opinion) — Strength of recommendation (Weak)

In pharmacological treatment of Hand OA, chondroitin sulfate among SYSADOAs has demonstrated efficacy for pain and function in some studies. Topical NSAIDs remain the first topical pharmacological choice due to safety reasons and moderate short-term functional effect; oral NSAIDs may be considered for limited use for pain relief. Corticosteroid injections show promise in acute phases, but overall require further evidence. Biologic agents to date have shown limited or no significant benefit. Conventional or biological disease-modifying antirheumatic drugs are generally not recommended, although isolated studies suggest methotrexate may have a modest long-term effect on pain in synovitis-positive subsets. PubMed

Conclusion: As a result of this literature survey, it is concluded that optimal management of Hand OA requires a combination of non-pharmacological and pharmacological treatment modalities individualized to the patient's needs. Exercise to improve function and muscle strength, alongside pain reduction strategies, should be considered for every patient. Education and training in ergonomic principles, activity pacing, and use of assistive devices should be offered to every patient. Orthoses and other supportive devices are strongly recommended components of comprehensive hand OA care.

UPDATE IN MUSCULOSKELETAL CONDITIONS WITH HAND INVOLVEMENT: 2-SOFT TISSUE LESIONS /NON ARTICULAR INVOLVEMENT OF HAND

A. Winkelmann[1]

[1]Physical and Rehabilitation Medicine (PRM), Department of Orthopaedics and Trauma Surgery, Musculoskeletal University Center Munich (MUM), University Hospital LMU Munich, Germany, München, Germany

Introduction

Soft tissue musculoskeletal disorders (MSDs)/ lesions refer to regional and generalized pain conditions and describe a broad spectrum of health problems, most of them poorly defined according to diagnostic criteria and case definitions (1). Here we want to focus at regional arm/wrist/hand conditions with non-articular involvement of hand.

Purpose:

The aim is

- to present biopsychosocial risk factors, risk groups and trends, preventive/ conservative therapeutic/ rehabilitative strategies for functional health in the case of regional soft tissue lesions, and non-articular wrist/hand involvements.
- to point out the need of research to improve evidence for diagnostic, preventive, therapeutic and rehabilitative strategies for functional health in the case of regional soft tissue lesions/ complaints, and non-articular wrist-/ hand involvements.

Methods:

A systematic literature search was performed to identify all randomized controlled trials, systematic reviews, addressing risk factors and groups, prevention, conservative therapy and rehabilitation of musculoskeletal and non-articular soft tissue involvement, lesions and disorders of the hand. Using the MEDLINE, Embase, the Cochrane Library, PEDro and UptoDate.

Results:

Regional pain and disorders, nonarticular involvement of hand region, may reflect soft tissue conditions within the hand or as referred pain from a proximal region

Soft tissue lesions within the hand can be classified into benign and malignant entities. Common benign lesions/ pain conditions include tenosynovitis/ trigger finger, ganglion cysts, fasciitis/ Dupuytren´s palmar contracture, Carpal tunnel syndrome, lipomas, infections, and fibromas, while malignant tumors, such as sarcomas, are less frequent but can lead to significant morbidity (1, 2). Ganglion cysts, in particular, are prevalent among athletes and individuals engaged in repetitive hand activities (e.g. musicians), highlighting the role of occupational exposure as a bio-risk factor. Lipomas, often asymptomatic, can occur in various populations, while neuromas are frequently seen in patients with a history of nerve injuries or surgeries (3).

Common disorders with referred pain to hand from a proximal region are myofascial pain, epicondylitis, tendinopathy/ tendinitis/ tenosynovitis, enthesitis, bursitis or structural lesions/ disorders (such as hyperlaxity), neurovascular entrapmet disorders (carpal tunnel syndrome). (1, 2)

Many physical, psychosocial and work-related factors play a role in etiology and prognosis. There is a lack of evidence for the management of most soft tissue disorders with therapeutic and rehabilitative strategies. Also good prevention policy does not exist for most conditions, due to the lack of knowledge on risk factors, risk groups and trends.(1) The work-related characteristics such as vibration, repetitiveness, work posture and force can play a role as risk factors for arm/wrist/hand conditions. In forearm pain, high levels of distress and adverse psychosocial factors are associated with the onset of symptoms.(1)

Diagnostic classification of symptoms and functional capacity as well as psychosocial risk factors is crucial as the basis for selecting appropriate therapy and rehabilitation strategies:

- Medical history (questions about trauma, repetitive movements, type/location/modality of symptoms (e.g., stabbing, burning, pulling, etc.), psychosocial history)
- Physical examination (including inspection for possible injuries/ signs of synovial fluid, assessment of active/passive range of motion, ligament stability, nerve function, and palpation of space-occupying lesions, comparing both sides), and
- Imaging (ultrasound (US) for superficial space-occupying lesions (e.g., lipomas), and, if red flags are present, MRI for detailed visualization of soft tissue and nerves; X-ray for bone findings (less helpful for purely soft tissue lesions)) are essential for differential diagnosis.

There is low-level evidence on preventing work-related musculoskeletal disorders (MSDs) for participants using computers with supplementary breaks.(3) Risk groups for upper limb MSDs/ overuse are characterized by beeing overweight due to stress over functional capacity.(4) Elite musicians, in particular, appear to be at risk for overuse injuries similar to elite athletes (point prevalence for musicians of playing-related musculoskeletal disorders up to 47%, with the hand and wrist being among the most frequently affected areas, and lifetime prevalences up to 89%). (5, 6) Strategies to adapt individually suitable instrument positions seem to minimize strenuous and potentially unhealthy compensation movements of the left upper extremity in violin playing musicians (7).

While initial indications of helpful strategies from small clinical studies exist, but evidence is still lacking, particularly for the frequently occurring overuse syndromes, the following points should be investigated in randomized controlled trials in at-risk groups such as adolescent and adult elite athletes and elite musicians:

- Preventive strategies (e.g., warm-up, cool-down, ergonomic exercise/ training, and breaks) and
- Therapies (e.g., manual therapies, device-assisted therapies, laser therapy, shockwave therapy, psychotherapeutic techniques, and newer therapeutic strategies including augmented reality training).

Conclusion:

Work-related physical and psychosocial factors can play a role as risk factors for soft-tissue arm/wrist/hand conditions. There is low-level evidence for supplementary breaks to prevent work-related MSDs. Because the study results only relate to specific professions, they cannot be representative for the general population.

THE NEUROLOGICAL SYMPHONY: RHYTHMIC AUDITORY-MOTOR COUPLING AND DUAL-TASK TRAINING EFFECTS OF EURHYTHMICS ON BALANCE AND EXECUTIVE FUNCTION

N. Gadallah[1]

[1]Prof. Rheumatology and Rehabilitation Ain Shams University, Cairo, Egypt

Geriatric population requires physical exercises and various interventions that help to improve their balance, coordination, range of motion, strength, endurance and gait function.

Dalcroze Eurhythmics is a music education method that teaches musical understanding through body movement, rhythm, and physical expression. Neurologic music therapy, a crucial complementary therapy, is currently used in the rehabilitation of movement, speech, and cognition and is accepted in the medical field.

Various biofeedback modalities, including auditory, visual, tactile, and vibrotactile feedback, have been used to optimize motor learning. Among these, rhythmic auditory stimulation (RAS) is widely applied because regular rhythmic cues can synchronize motor and sensory regions. RAS uses an external rhythm (music) to facilitate internally generated rhythmic movements, such as walking. Its effectiveness is supported by strong neuroanatomical connectivity between auditory and motor areas and by the auditory system's faster stimulus processing compared to visual or tactile inputs.

Dual task training can be defined as performing two activities simultaneously together with coordination. Dual-task training with RAS—which combines rhythmic movement with cognitive tasks—has been shown to improve balance, gait, and executive function in older adults, while also reducing fall risk. It enhances both physical stability and cognitive flexibility by engaging motor and cognitive systems simultaneously.

NSS44

THE MOVING BODY: DEVELOPING A SCALABLE AND SAFE DALCROZE PROTOCOL FOR OLDER ADULTS WITH VARYING COGNITIVE AND PHYSICAL LIMITATIONS IN RESIDENTIAL CARE

M. Hassan Abu Zaid[1]

[1]Prof. Rheumatology and Rehabilitation Tanta University, Tanta, Egypt

As the global population of older adults in residential care increases, there is an urgent need for non-pharmacological interventions that address the "whole person, "integrating physical, cognitive, and social well-being. While traditional exercise programs often struggle with high heterogeneity in resident ability, **Dalcroze Eurythmics (DE)** offers a uniquely adaptable solution by integrating music and movement to stimulate the perception-action loop. This presentation introduces a specialized, scalable Dalcroze protocol designed to bridge the gap between clinical effectiveness and the practical constraints of long-term care environments.

The proposed DE protocol focuses on three core pillars:

- **Safety & Accessibility:** Utilizing seated or supported movement sequences that accommodate residents with restricted mobility, such as those with musculoskeletal conditions or high fall risk.
- **Cognitive Enrichment:** Incorporating rhythmic "reflection-in-action" tasks that support executive function, dual-task performance, and procedural memory, which are critical for residents with mild-to-moderate dementia.
- **Scalability in Care Settings:** Designing sessions that can be delivered in group circles to maximize social connection while requiring minimal specialized equipment, allowing for seamless integration into existing institutional routines.

Evidence from clinical collaborations indicates that regular DE practice can reduce fall rates by more than **50%** and induce positive structural changes in the brain. By emphasizing improvisation and joy over rigid physical output, this protocol transforms therapeutic intervention into a meaningful social experience. Attendees will gain practical insights into implementing a "Buy One, Get One Free" approach that intercepts physical decline while simultaneously fostering cognitive resilience and emotional flourishing in older adults.

NSS45

BEYOND FALLS: ASSESSING THE IMPACT OF DALCROZE EURHYTHMICS ON QUALITY OF LIFE, SOCIAL ENGAGEMENT, AND CARE HOME SERVICE COST-EFFECTIVENESS

Y. El Miedany[1]

[1]Prof. Rheumatology and Rehabilitation Ain Shams University, Cairo, Egypt

Background: Cognitive and functional decline in care home residents often leads to social isolation, decreased Quality of Life (QoL), and rising institutional costs. While exercise programs are traditionally implemented for fall prevention, the holistic benefits of rhythmic, music-based interventions are frequently undervalued. Dalcroze Eurhythmics—a method integrating music, rhythm, and physical movement—offers a multidomain approach to preserving **Intrinsic Capacity (IC)** by simultaneously engaging the locomotor, cognitive, and psychological domains.

This presentation will discuss the implementation of a structured Dalcroze Eurhythmics program within residential care settings. Moving beyond traditional gait and balance metrics, the research utilized a mixed-methods approach to assess: (1) **Psychosocial Impact:** changes in social engagement and loneliness scales; (2) **Functional QoL:** patient-reported outcomes regarding independence and mood; and (3) **Economic Viability:** a cost-effectiveness analysis of service delivery versus long-term care requirements (e.g., reduced medication for agitation and lower injury-related hospitalizations).

The preliminary data suggest that Dalcroze Eurhythmics significantly enhances social cohesion among residents, creating a shared rhythmic "language" that mitigates isolation. Participants demonstrated improved executive function and "purposeful movement," which translated to higher QoL scores compared to sedentary control groups. Most notably, the intervention proved cost-effective; the initial investment in trained practitioners was offset by a measurable reduction in the utilization of "as-needed" (PRN) psychotropic medications and a decrease in the intensity of caregiver assistance required for daily mobility.

Regarding the cost effectiveness: the technique has helped to:

Reduce "Agitation" Costs: Linking rhythmic engagement to lower levels of sundowning and restlessness, which reduces staff "one-to-one" time.

Functional Longevity: Every month a resident maintains their ability to transfer or walk independently saves the facility significant costs in mechanical lift usage and skin integrity management.

In summary, endorsing the "Music-Brain-Body" link, Dalcroze Eurhythmics represents a potent, multidomain intervention that transcends basic fall prevention. By integrating music and rhythm into clinical care, facilities can preserve the intrinsic capacity of residents while improving the social fabric of the care home environment. It also highlights the role of group rhythm in reducing the "silent epidemic" of loneliness in care homes, endorsing the social capital gains.This evidence-based approach advocates for the inclusion of rhythmic interventions as a standard, cost-effective component of holistic geriatric care.

NSS46

INTRODUCTION: THE NEED FOR PRAGMATIC APPROACHES FOR PATIENTS AT RISK

J. L. A. Morales-Torres[1], O. D. Messina[2]

[1]Morales Vargas Centro de Investigación and Hospital Aranda de la Parra, León, Mexico; [2]IRO Medical Center, Investigaciones Reumatológicas y Osteológicas SRL, Buenos Aires, Argentina

The onset of sarcopenia with advancing age results in a decline in strength and function and contributes to clinically important outcomes, including disability, an increased risk of falling and higher mortality1. The prevalence of sarcopenia estimated from 10 to 16% of elderly population worldwide2, has been reported in higher frequency in several rheumatic diseases, and depends on definition used3. Definition, in terms of developing evidence-based diagnostic limits of lean mass and/or muscle strength capable of identifying persons at risk for mobility disability and related endpoints is an ongoing effort from relevant groups of professionals. The Global Leadership Initiative in Sarcopenia (GLIS), has proposed a conceptual definition for sarcopenia, including muscle mass, muscle strength and muscle-specific strength as “components” of sarcopenia, leaving impaired physical performance as an “outcome”, more than a component1. Operational definition will require establishing cut points for lean mass and strength assessments for different populations4.

Therapeutic approaches for prevention and treatment of sarcopenia are currently limited to nutrition and exercise modalities. Markers of a higher risk for muscle impairment in rheumatic diseases include inflammation and joint pain, physical limitations and glucocorticoids, among others3. Although some of these patients may not fulfill the current definition of sarcopenia, it would be advisable to include nutrition and exercise interventions to limit the adverse outcomes1,3.

The purpose of this Symposium is to explore the current concepts of muscular affection in patients with rheumatic diseases; to describe prevention, early detection and diagnostic approaches in patients with specific joint limitations as well as to propose pragmatic approaches for patients at risk.

MUSCLE IMPAIRMENT: THE PROBLEM WITH OUTCOMES

G. Duque[1]

[1]Bone, Muscle & Geroscience Group, Research Institute of the McGill University Health Centre, Montreal, Canada

Muscle loss and dysfunction are highly prevalent complications of rheumatic diseases, including rheumatoid arthritis, spondyloarthritis, systemic lupus erythematosus, and inflammatory myopathies. Driven by chronic inflammation, physical inactivity, pain, glucocorticoid exposure, and metabolic dysregulation, muscle impairment in these conditions substantially contributes to fatigue, disability, falls, fracture risk, and reduced quality of life. Despite its clinical relevance, the assessment of muscle outcomes in rheumatology research remains fragmented and inconsistent.

Studies of muscle loss in rheumatic diseases employ a wide range of outcomes, including lean mass, muscle cross-sectional area, strength measures, physical performance tests, and patient-reported function. These outcomes are often used interchangeably, with limited consideration of their construct validity, sensitivity to change, or relationship to clinically meaningful endpoints. Inflammatory disease activity further complicates interpretation, as fluctuations in inflammation and treatment response may differentially affect muscle mass and function. As a result, improvements in surrogate measures such as lean mass do not consistently translate into gains in strength, mobility, or patient-relevant outcomes.

This presentation will examine the specific challenges of outcome selection for muscle impairment in rheumatic diseases, highlighting sources of heterogeneity across disease states, treatments, and study designs. We will discuss the limitations of current approaches, including the overreliance on mass-based measures and the underrepresentation of functional and patient-centered outcomes. Emerging strategies to harmonize outcome reporting—such as core outcome sets, disease-agnostic functional endpoints, and integrated models linking inflammation, muscle function, and clinical events—will be reviewed.

NSS48

MUSCLE IMPAIRMENT: ADAPTING DIAGNOSIS TO JOINT LIMITATIONS

J. L. A. Morales-Torres[1]

[1]Morales Vargas Centro de Investigación and Hospital Aranda de la Parra, León, Mexico

Handgrip strength (HGS) measured with a hand-held dynamometer, is widely used. Simple and inexpensive, it is a biomarker for overall health, muscle function, and an indicator of future health risks. Results should be interpreted by comparing an individual's measured grip strength to cut-off reference values. These are influenced by ethnic origin, age, sex, level of education and type of activities performed1. In patients with rheumatoid arthritis HGS is a useful tool to evaluate hand disability2, an indicator of the risk of frailty3 and an instrument to evaluate muscle function4, but interpretation may be difficult for this last purpose, in patients with severe inflammation or articular damage2-4. Evaluation of muscle health in these patients beyond HGS, may include the use of SARC-F questionnaire; muscle mass measured by any available technique and probably gait speed or other functional evaluation1-4.

Rheumatic inflammatory conditions frequently cause muscle dysfunction. It tends to be worse in older patients and in those with more inflammation, joint damage and immobility. Glucocorticoids, Vitamin D deficiency and co-morbidities worsen that impact5. These factors should alert clinicians to deepen the diagnostic process and to consider nutritional and exercise modalities for a broader range of patients to limit the impact of muscle impairment.

MUSCLE IMPAIRMENT IN RHEUMATIC DISEASES: PRIMARY AND SECONDARY PREVENTION TODAY

O. D. Messina[1]

[1]IRO Medical Center, Investigaciones Reumatológicas y Osteológicas SRL, Buenos Aires, Argentina

Muscle loss is linked to multiple adverse outcomes in chronic rheumatic diseases including higher mortality. Sarcopenia in rheumatic diseases is more frequent than in the general population leading to falls and fractures.

Measures to improve it are as follows:

1 Control the underlying disease as soon as possible to induce clinical remission.

2 Maintain mobility and physical activity.

3 Maintain adequate nutrition including proteins and calcium in the diet.

4 Maintain levels of Vitamin D higher than 40 ng /ml in serum, prescribing Vitamin D supplements .

5 Follow a physical activity program including active exercises and muscle strength exercises.

All these concepts may apply to patients with rheumatoid arthritis, Systemic Lupus Erythematosus and psoriatic arthritis as well as other rheumatic diseases. It is also very important to reach adequate body weight in those patients with sarcopenic obesity .

Future investigations in this field are clearly warranted .

MULTIMORBIDITY CONTRIBUTES TO THE OSTEOPOROSIS TREATMENT GAP

D. Bliuc[1,2], T. Thach Son[1], M. Lin[3,4,5], D. A. Alajlouni[1], W. Chen[1,2], A. Sheu[1,5], R. D. Blank[1,5], J. R. Center[1,5,6]

[1]Bone Epidemiology, Clinical and Translation Science Lab, Garvan Institute of Medical Research, Darlinghurst NSW, Australia; [2]Medical College of Wisconsin, Milwaukee, United States; [3]School of Biomedical Engineering, University of Technology, Sydney NSW, Australia; [4]St Vincent's Clinical School, Faculty of Medicine and Health UNSW, Darlinghurst NSW , Australia; [5]Department of Endocrinology, St Vincent's Hospital, Darlinghurst NSW , Australia; [6]Department of Endocrinology, Royal Prince Alfred Hospital, Camperdown NSW, Australia

Objective: Fractures are associated with increased risks of subsequent fracture and premature mortality. Most real-world fracture patients have multimorbidity, yet secondary fracture prevention evidence largely derives from RCTs enrolling relatively healthy individuals (2). We examined the burden of multimorbidity among fracture patients and its association with fracture prevention management and post-fracture outcomes (1,3).

Materials and Methods: Study population comprised participants from 45 and Up Study (n=267,153), a prospective cohort in New South Wales, Australia, with questionnaire data linked to hospital admissions, emergency presentations, pharmaceutical dispensing, and medical services (2005–2017). Incident fractures were identified from hospital and emergency records. Multimorbidity was assessed using the Charlson Comorbidity Index (CCI) and self-rated health. In a high-risk fracture subgroup (10-year fracture risk ≥20%), associations between multimorbidity and post-fracture osteoporosis investigation (DXA) and treatment initiation were examined using adjusted logistic regression. In the broader fracture cohort, associations with subsequent fracture and mortality were examined using Cox models (3).

Results: Over 40% of high-risk fracture patients had CCI ≥2. Despite high fracture risk, management was suboptimal: only 17% of females and 7% of males received DXA investigation, and 22% of females and 14% of males initiated treatment following fracture. Increasing multimorbidity was independently associated with lower likelihood of investigation and treatment. Compared with CCI <1, those with CCI ≥4 had markedly reduced odds of DXA referral (OR range 0.43–0.52) and treatment initiation (OR range 0.37–0.78). In the broader fracture cohort, higher multimorbidity was associated with increased risks of subsequent fracture (~30–40% higher) and all-cause mortality (~50–70% higher) (3).

Conclusion: Multimorbidity is common among fracture patients and is associated with under-investigation, under-treatment, and substantially worse post-fracture outcomes. These findings highlight the need for incorporating multimorbidity into fracture prevention guidelines.

NSS51

MULTIMORBIDITY DOUBLE BURDEN: ELEVATED REFRACTURE RISK DESPITE HIGH MORTALITY FOLLOWING FRACTURES

M. Lin[1,2,3], T. Tran[1,4], D. A. Alajlouni[1], W. Chen[1,5], A. Sheu[1,6], R. Blank[1,5], D. Bliuc[1,7], J. R. Center[1,2,6]

[1]Bone Epidemiology, Clinical and Translation Science Lab, Garvan Institute of Medical Research, Darlinghurst, Australia; [2]St Vincent's Clinical School, Faculty of Medicine and Health UNSW, Darlinghurst, Australia; [3]Department of Endocrinology, Royal Prince Alfred Hospital, Camperdown, Australia; [4]School of Medical Engineering, University of Technology, Ultimo, Australia; [5]Medical College of Wisconsin, Milwaukee, United States; [6]Department of Endocrinology, St Vincent's Hospital, Camperdown, Australia; [7]North Wales Medical School, Bangor University, Wales, United Kingdom

Objective: Multimorbidity (MM), defined as presence of ≥ 2 chronic conditions, affects more than half of individuals with fractures and is associated with excess mortality. However, its impact on refracture risk is unclear. This study aimed to quantify refracture risk across MM clusters and fracture sites to identify high-risk groups.

Methods: Whole-population data linkage cohort study of 2,308,583 adults aged ≥ 50 years living in New South Wales (NSW), Australia, with at least one hospital or emergency admission between 1 Jan 2005 and 30 June 2022. Among them, individuals with fractures between 1 Jan 2005 and 30 June 2021 were followed until 30 June 2022 for refracture and mortality outcomes. Fractures and 60 predefined comorbidities associated with fracture risk, falls, musculoskeletal disease or mortality were identified using ICD-10 and SNOMED-CT

codes. Latent class analysis (LCA) was used to identify MM clusters within the fracture cohort. Sex-specific Fine-Gray subdistribution and Cox proportional hazards models estimated refracture and mortality risk, stratified by fracture site (hip, vertebral, proximal, distal).

Results: Among 335,308 individuals with fractures, 31.2% were men (mean [SD] age, 76.3 [10.7] years) and 68.8% were women (77.4 [10.7] years). LCA identified six clusters in both sexes: five MM clusters (cardiovascular, cardiometabolic, geriatric, cancer, mental health; median comorbidity count: 4-13) and one low MM cluster (median count: 0). When compared to the general NSW populaton risk of incident fracture and death, all clusters were associated with increased refracture risk (HR range: 2.04-2.84 in men, 1.44-2.05 in women) despite substantial competing mortality (HR range: 1.47-4.51 in men, 1.07-3.07 in women). The mental health cluster had the highest refracture risk, while distal fractures were associated with higher refracture risk due to lower mortality.

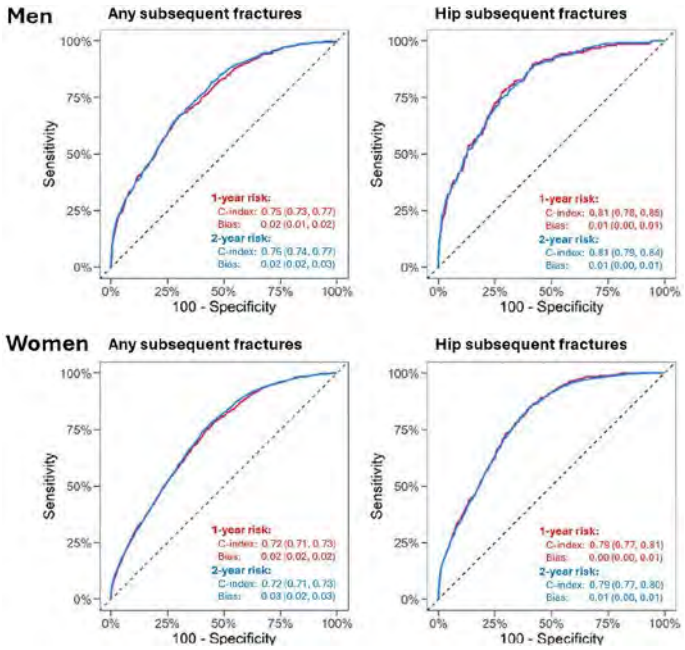
Conclusion: Multimorbid individuals with fractures remain at substantial risk of refractures despite elevated mortality, particularly those with mental health conditions and distal fractures. These findings highlight the need for targeted secondary fracture prevention in MM populations, especially for non-hip non-vertebral sites that are not traditionally considered.

NSS52

RISK STRATIFICATION FOR IMMINENT SUBSEQUENT FRACTURES: A DEEPHIT APPROACH USING ADMINISTRATIVE HEALTH DATA

H. Nguyen[1], T. Tran[1], D. Bliuc[1], R. Blank[1], C. White[1], J. Center[1]

[1]Skeletal Diseases Program, Garvan Institute of Medical Research, Sydney, Australia



Early identification of patients at risk of subsequent fractures is crucial for optimising post-fracture care, particularly given the emerging evidence on imminent fracture risk. . We developed and validated a deep learning model to predict the 1- and 2-year risks of subsequent hospitalised fractures using routinely collected administrative health data.

This statewide population-based cohort study included 269,294 adults in New South Wales, Australia, born on or before 01 January 1950, who sustained an incident fracture between 2005 and 2017 and were followed through 2022. Fractures and 65 predefined chronic diseases related to fractures and mortality were identified using the ICD-10 codes recorded within 5 years of the index fracture. We used *DeepHit* approach to predict the risk of imminent subsequent fracture, accounting for complex non-linear data and competing mortality risks. Model performance was assessed using discriminative and calibration analyses.

Over a median follow-up of 5 years (IQR: 1.5-8.6), 13,358 men and 46,222 women were admitted for a subsequent fracture, yielding the incidence of 31.2 (95% CI: 30.6-31.7) and 42.9 (42.5-43.3) per 1,000 person-years, respectively. Subsequent hip fracture incidence was 5.3 (5.1-5.4) and 8.0 (7.9-8.1)/1,000 person-years in men and women, respectively. Predictors included age, index fracture site, prior fractures or falls, and 1,870 ICD-10 codes of the predefined chronic diseases. Neither BMD nor weight was included. The model showed strong discrimination and calibration for predicting subsequent fractures at any site and hip (Figure). For 1-year risk of subsequent hip fractures, the C-indices were 0.81 (95% CI: 0.78-0.85) in men and 0.79 (0.77-0.81) in women; and bias was 0.01 (0.00-0.01) in both sexes. For 1-year risk of any subsequent fractures, the C-indices were 0.75 (0.73-0.77) and 0.72 (0.71-0.73) in men and women with biases of 0.02 (0.01, 0.02) and 0.02 (0.02, 0.02), respectively.

Our model accurately identified individuals at imminent risk of subsequent fractures using routinely collected administrative health data, highlighting its potential for automated risk stratification within the healthcare system.

Figure 1. Performance of the *DeepHit* Model for Predicting Imminent Risk of Subsequent Fractures using Routinely Collected Administrative Health Data

NSS53

LOW-DOSE RADIOTHERAPY IN DEGENERATIVE MUSCULOSKELETAL DISORDERS: FROM RADIOBIOLOGICAL PRINCIPLES TO CLINICAL PRACTICE

A. Fernández Forné[1]

[1]Coordinator of Benign Disease Unit at Quirónsalud Málaga Hospital, Malaga, Spain

Objective:

Low-dose radiotherapy (LDRT) is increasingly recognized as a therapeutic option for patients with certain degenerative musculoskeletal disorders, particularly those that do not respond to conventional treatments. This presentation aims to review the radiobiological and pathophysiological mechanisms underlying LDRT's anti-inflammatory and immunomodulatory effects and to translate this knowledge into clinical practice.

Material and Methods:

This presentation is based on a narrative review of the available radiobiological and clinical evidence supporting the use of LDRT in degenerative and inflammatory musculoskeletal conditions, following the European treatment protocols and its indications. A review of the

mechanisms by which LDRT modulates inflammatory pathways, immune cell activity and microvascular processes at the joint and periarticular level has been conducted, along with the practical aspects of treatment delivery, including dose, fractionation schedules and modern radiotherapy techniques.

Results:

LDRT, typically 3-6 Gy in 0.5-1.0 Gy fractions, demonstrates anti-inflammatory and immunomodulatory effects that translate into pain relief and functional improvement in selected patients. Current clinical indications include osteoarthritis, periarticular soft tissue disorders, enthesopathies, tendinopathies, trochanteric pain syndrome, plantar fasciitis and degenerative disorders of the hand. Modern treatment planning and delivery techniques allow accurate targeting of the affected structures while minimizing exposure to surrounding tissues. The incidence of acute and late adverse effects is minimum, and the theoretical risk of radiation-induced malignancies is considered extremely low with the doses currently used.

Conclusions:

LDRT is a safe and effective therapeutic option with a favorable risk-benefit profile for carefully selected patients with degenerative musculoskeletal disorders that should be considered as part of a multidisciplinary therapeutic approach.

BEYOND CONVENTIONAL THERAPIES: A RHEUMATOLOGIST'S PERSPECTIVE ON THE MANAGEMENT OF COMPLEX AND REFRACTORY PATIENTS

N. Costas Torrijo[1]

[1]Head of Department of Rheumatology of Quirónsalud Marbella Hospital, Marbella, Spain

Objective:

To review the inflammatory pathophysiology of osteoarthritis and degenerative processes and establish rigorous selection criteria for identifying patients who may benefit from low-dose radiotherapy (LDRT) based on imaging tests findings and biomarker analyses.

Material and Methods:

Narrative review of current evidence on the role of inflammation in osteoarthritis, including inflammatory mediators (IL-1β, IL-6, TNF-α), serum and synovial biomarkers and imaging studies identifying active inflammation process. Clinical and preclinical studies on LDRT in osteoarthritis were analyzed, evaluating its efficacy during the inflammatory phase. A practical framework was established to identify refractory patients based on clinical, radiographic, and laboratory criteria.

Results:

Osteoarthritis is characterized by chronic low-grade inflammation mediated primarily by the innate immune system, with involvement of proinflammatory cytokines, chemokines, and growth factors that establish an imbalance between anabolic and catabolic processes. LDRT (typically 3-6 Gy in 0.5-1.0 Gy fractions) exerts anti-inflammatory effects through macrophage polarization, reduction of proinflammatory cytokines (IL-17, IL-4), and systemic modulation of immune cells. Recent studies demonstrate significant pain reduction with sustained benefit at 8-10 weeks, with 72-80% of patients showing clinical improvement. Imaging modalities, particularly contrast-enhanced MRI and ultrasound, can identify active synovitis and guide patient selection. Refractory patients typically present with moderate-to-severe persistent pain after >6 months of conservative therapies (exercise, NSAIDs, intra-articular injections), radiographic evidence of structural changes and signs of active inflammation on imaging studies.

Conclusions:

LDRT represents a noninvasive and effective therapeutic option for patients with refractory osteoarthritis, particularly during the active inflammatory phase. Rigorous patient selection through clinical criteria, imaging studies demonstrating synovitis, and emerging inflammatory biomarkers is fundamental to optimize outcomes. This evidence- based multidisciplinary approach allows identification of ideal candidates who have failed to conventional therapies but are not surgical candidates or prefer noninvasive options, especially in elderly populations where the safety profile of LDRT is favorable.

NSS55

BUILDING CLINICAL EVIDENCE: PRELIMINARY RESULTS FROM THE FINGERT AND TROCANTERT STUDIES

J. Pardo Masferrer[1]

[1]Head of Department of Radiation Oncology and Coordinator of Benign Disease Unit of Hospital Universitari General de Catalunya, Quirónsalud, Barcelona, Spain

Objective:

To present preliminary results from two prospective observational studies evaluating the efficacy and safety of low-dose radiotherapy (LDRT) for hand and finger joint pain (FINGERT) and greater trochanteric pain syndrome (TROCANTERT) in patients treated at Hospital Universitari General de Catalunya.

Material and Methods:

Two prospective observational studies were conducted. In the FINGERT study, patients with painful hand and finger osteoarthritis refractory to conventional therapy were enrolled. In the TROCANTERT study, patients with greater trochanteric pain syndrome (trochanteritis) were included. The radiotherapy protocol consisted of 3Gy delivered in 6 fractions of 0.5Gy on alternate days. Reassessment was performed at 2 months; partial responders or non-responders received a second course of 6Gy in 6 fractions of 1Gy on alternate days. Pain and functional outcomes were evaluated using the Visual Analogue Scale (VAS) and the Von Pannewitz scale, a validated 4-point scale measuring patient- assessed improvement (complete pain relief, marked improvement, slight improvement, no change).

Results:

With a median follow-up of 8 months, the FINGERT study included 92 hands. Overall response rate was 86%, with 50.8% achieving complete response. These results are consistent with published literature reporting 70% improvement rates in finger osteoarthritis treated with LDRT, with 0.5Gy fractions showing superior outcomes. The TROCANTERT study included 182 joints, demonstrating an overall response rate of 74.5%, with 43% achieving complete response. These findings align with previous studies reporting 59-64% response rates for greater trochanteric pain syndrome treated with LDRT. Mobility and pain improvements were observed in both cohorts. No significant adverse effects were recorded.

Conclusions:

These preliminary results from the FINGERT and TROCANTERT studies support the efficacy and safety of LDRT in selected degenerative musculoskeletal disorders. The response rates observed are comparable or superior to those reported in the literature, particularly for hand osteoarthritis. The two-course protocol with dose escalation for non-responders appears to optimize outcomes. These prospective data contribute to building clinical evidence for LDRT as a noninvasive therapeutic option in patients refractory to conventional treatments, supporting its integration into multidisciplinary management pathways for benign painful musculoskeletal conditions.

EARLY DETECTION OF VERTEBRAL FRAGILITY FRACTURES: BRIDGING THE DIAGNOSTIC GAP

L. C. Semedo[1,2]

[1]Radiology Department, ULS Aveiro Region, Aveiro, Portugal; [2]Clinical Academic Center Egas Moniz Health Alliance, Aveiro, Portugal

Vertebral fragility fractures are common yet frequently underdiagnosed, often identified incidentally on imaging studies performed for unrelated indications. Despite their strong association with future fracture risk and adverse clinical outcomes, many of these fractures remain unrecognized, leading to missed opportunities for timely intervention.

This educational session aims to highlight practical strategies to improve case finding and early detection of vertebral fragility fractures using imaging, bone densitometry, and emerging artificial intelligence (AI) tools. The complementary roles of opportunistic assessment on routine radiographs, CT, and MRI, as well as vertebral fracture assessment (VFA) by densitometry, will be discussed. In addition, the potential of AI-based algorithms to support automated fracture detection, risk stratification, and workflow integration will be explored.

By fostering closer integration between imaging findings and clinical decision-making, this session seeks to support clinicians in recognizing vertebral fragility fractures and promoting timely assessment and management of osteoporosis.

NSS57

OPPORTUNISTIC DIAGNOSIS OF VERTEBRAL FRACTURES USING ROUTINE CT SCANS: THE PORTUGUESE EXPERIENCE AND LITERATURE REVIEW

A. P. Barbosa[1,2]

[1]Fracturary Osteoporosis Outpatient Clinic. Endocrinology Department, ULS Santa Maria Lisboa, Lisbon, Portugal; [2]Lisboa Faculty of Medicine, University of Lisbon, Lisbon, Portugal

Vertebral fractures (VF) are among the most common fractures in osteoporotic patients (about 50%) and consequently they are approximately five times more likely to develop an additional VF and are twice as likely to suffer a hip fracture with resulting morbidity and mortality. The mid-thoracic region and thoracolumbar junction are the most commonly affected areas and often lead to spinal kyphotic deformities which predisposes to loss of balance, muscle fatigue, degenerative changes of intervertebral joints, restrictive lung disease and further sedentarism/immobilization.

Most radiologists frequently miss or do not report VFs when imaging is requested for an alternative clinical indication and so, that is a missed opportunity to improve the burden of osteoporotic fractures.

The imaging modalities to identify VF are plain films (anteroposterior and lateral projections), CT, MRI (STIR sequence) and bone scintigraphy.

During one year, in a tertiary hospital with an already implemented Fracture Liaison Service (FLS) programme, 2 imagiologists prospectively analysed 430 thoracic, abdominal and pelvic CT scans performed for other diagnostic purposes, in order to identify VF. Two hundred and six patients (48%) were identified with VF, 74 patients (36%) were eligible for osteoporosis management and 68 patients (33%) died during the data collection; these were significantly older (84 vs. 75 years, $p < 0.01$) and more frequently had ≥2 VF (47% vs. 28%, $p = 0.02$). Twelve patients (16%) had a previously known fragility fracture and had never been on anti- osteoporotic drugs.

The Portuguese work has shown that within one year of opportunistic CT-scan evaluation, a vulnerable population could be identified for osteoporosis management and fracture risk reduction intervention measures. It also helped to understand that untreated and undiagnosed VFs can significantly impact on a patients quality of life and life expectancy. Inappropriate terminology in the CT reports may be confusing and non-diagnostic, so basic education programmes delivered to radiologists could help to improve diagnosis leading to early detection and treatment of VF.

More recently, VF detection algorithms are being developed to work in a real-life setting and show promising good sensitivity and specificity; this AI technology can help to improve the efficiency of the FLS.

NSS58

ASSESSING QUALITY OF LIFE AFTER VERTEBRAL FRACTURE: THE VALUE OF THE PORTUGUESE-VALIDATED QUALEFFO-41 OVER GENERIC INSTRUMENTS

S. Azevedo[1,2]

[1]Rheumatology Department, ULS Aveiro Region, Aveiro, Portugal; [2]Clinical Academic Center Egas Moniz Health, Alliance, Aveiro, Portugal

Osteoporotic vertebral fractures are common, frequently under-recognized, and associated with a substantial and persistent burden that extends beyond pain alone. They can lead to impaired mobility, reduced physical function, sleep disturbance, fatigue, loss of independence, and emotional distress, with significant impact on patients' daily activities and social participation - dimensions that are not always captured by generic health status tools. This session will highlight how vertebral fracture–specific assessment can refine the evaluation of health-related quality of life (HRQoL) and strengthen clinical decision-making in routine practice and research. Using QUALEFFO-41 as a central example of a specific measure of HRQoL, we will discuss not only the importance of addressing HRQoL, but how a disease-specific approach can improve baseline and follow-up patient evaluation, by better characterizing symptom burden and functional impact. Finally, we will briefly review other available vertebral-fracture specific assessment tools and their applicability. The overarching objective is to provide clinicians with a more precise, patient-centered framework for monitoring outcomes and optimizing individualized management in patients with osteoporotic vertebral fractures.

NSS59

CLOSING THE CARE GAP: DEFINING A SCALABLE PATHWAY TO TRANSFORM BONE HEALTH EVALUATION ACROSS HEALTH SYSTEMS

R. Patel[1]

[1]Aegis Bone Health, Scottsdale, United States

Osteoporosis remains a major public health concern worldwide, yet significant treatment care gaps persist, contributing to preventable fractures, morbidity, and healthcare costs. A central driver of this gap is the lack of standardization in osteoporosis evaluation and assessment across clinical settings. Variability in screening practices, diagnostic criteria, fracture risk assessment tools, and thresholds for treatment initiation leads to inconsistent identification of at-risk individuals and delayed or missed interventions. Differences in laboratory evaluations for secondary causes and follow-up protocols further compound disparities in care. As a result, many patients who meet criteria for therapy remain untreated, while others receive suboptimal, or fragmented care. Inconsistent assessment frameworks undermine the continuity of care and limit the effectiveness of osteoporosis prevention strategies.

NSS60

INTEGRATING BIOLOGY, BEHAVIOR, FUNCTION, AND ENVIRONMENT: A 4-PILLAR FRAMEWORK DRIVING COMPREHENSIVE BONE HEALTH OPTIMIZATION

N. Koumontzis[1]

[1]West Virginia University, Morgantown, United States

A successful clinical process needs to be based upon inherent assessment and treatment algorithms. Our process, the Optimal Clinical Paradigm, consists of methods that are consistent, comprehensive, and reproducible. It begins with our 4-Pillar Assessment that engages the biological, behavioral, functional, and environmental factors that affect every patient and their bone health. Our 4-Pillar Assessment is an integrated data collection and assessment process that exists to evaluate all aspects of being human, as well as the environment in which we live. The biological pillar focuses on identifying and treating the physiological drivers of compromised bone health. Elements of this pillar include a risk factor analysis, physical assessment, appropriate laboratory and radiographic testing, and consultations with specialists, when indicated. The behavioral pillar serves as a comprehensive lifestyle and behavioral evaluation that is fundamental in identifying additional factors that promote decreased bone health and identifying blocks to patients' adherence to defined treatment care plans. This pillar is fundamental in supporting sustainable lifestyle changes that will improve overall success to selected treatment methodologies. The functional pillar evaluates a patients' functional movement, balance, and strength. A consultation with a physical therapist is scheduled to address any deficiencies. Therapists use our tailored protocol to work on muscle strengthening through weight bearing or resistance training, posture, balance, and gait training. Fall risk is evaluated and fall risk reduction techniques are utilized to educate patients regarding safe movement strategies and ergonomics, empowering them to stay active and independent while minimizing their risk of injury. The final pillar, environmental, focuses on creating a safe and supportive living environment that promotes mobility and reduces the risk of fall hazards. Perception of home safety by patients has proven to be different than their actual real living environment. We address this disparity in collaboration with occupational therapists and in-home assessments. Home modifications may be recommended, such as improved lighting, installation of grab bars, and non-slip flooring to ensure safety. Emergency contact devices may be recommended when indicated.

NSS61

MAPPING THE FUTURE: USING STRUCTURED ASSESSMENT TO GUIDE IMPLEMENTATION, DIRECTION, AND IMPACT IN BONE HEALTH CARE

P. D. Cummings[1]

[1]Aegis Bone Health, Scottsdale, United States

This exhaustive evaluation process translates into a Multi-disciplinary Assessment Profile or "MAP", which is used to develop a patient's Integrated Care Plan (ICP). While each plan is tailored to the individual needs of the patient, this methodology is consistent, comprehensive, and reproducible. Service lines for our program include men's bone health, women's bone health, peri-operative bone health optimization, post-fracture care, children and adolescents bone health, and athletic bone health. Despite the service line, all patients undergo the same initial evaluation, while patients perceived to be at a higher risk of fracture undergo a comprehensive multidisciplinary assessment, while patients at a low risk of fracture undergo an abbreviated multidisciplinary assessment. Incorporating comprehensive assessments and treatment modalities addresses the specific complexities of each individual patient and showcases the potential for improvement in how we care for patients throughout all facets of their lives. We believe our optimal clinical paradigm can narrow the existing treatment gap and improve patient outcomes.

NSS62

ANALYTICAL PRINCIPLES AND PERFORMANCE CONSIDERATIONS IN LC–MS/MS PROFILING OF VITAMIN D METABOLITES

E. Cavalier[1]

[1]Department of Clinical Chemistry, University of Liège, CIRM, CHU de Liège, Liège, Belgium

More than 50 vitamin D metabolites have been described, and growing evidence suggests that the catabolic arm of the pathway is not merely an "inactivation" route but a clinically informative and potentially biologically active axis. Beyond total 25(OH)D, quantifying 24,25(OH)₂D allows calculation of the vitamin D metabolite ratio (VMR = 24,25(OH)₂D/25(OH)D X100), which appears to better identify vitamin D deficiency and to improve clinical discrimination compared with 25(OH)D alone, including risk stratification for bone outcomes. 24,25(OH)₂D itself is increasingly viewed as biologically active, with data supporting roles in cartilage protection, fracture repair, and a protective association in bone stress injury. Clinically, 24,25(OH)₂D and VMR have become central for diagnosing idiopathic infantile hypercalcemia and, more broadly, for recognizing CYP24A1-related phenotypes, including heterozygous mutations presenting with PTH-suppressed hypercalcemia, elevated 25(OH)D and 1,25(OH)₂D even without supplementation, and an increased risk of nephrolithiasis. Metabolite profiling also offers mechanistic insight into the long-standing "vitamin D paradox" in African Americans, helping explain stronger skeletal outcomes despite lower total 25(OH)D by capturing differences in vitamin D catabolism (VMR) rather than relying on a single total 25(OH)D cut-off. Finally, earlier pharmacologic studies suggest that administering 24,25(OH)₂D may enhance calcium balance without increasing calcemia, raising questions about therapeutic applications and motivating a shift from single-analyte testing to targeted vitamin D metabolite profiling using specific methods like LC–MS/MS.

NSS63

VITAMIN D METABOLITE RATIO AS A FUNCTIONAL BIOMARKER ACROSS HEALTH OUTCOMES

N. Al-Daghri[1], S. Sabico[1]

[1]Chair for Biomarkers of Chronic Diseases, Department of Biochemistry, College of Science, King Saud University, Riyadh , Saudi Arabia

Growing evidence suggests that conventional serum 25-hydroxyvitamin D [25(OH)D] may not fully reflect functional vitamin D status. Across several complementary studies spanning older adults and adolescents, we evaluated the vitamin D metabolite ratio (VMR; 24,25(OH)D/25(OH)D) as an integrative biomarker of bone health, metabolic risk, and clinical outcomes. Using LC-MS/MS–based profiling, VMR consistently demonstrated stronger physiological relevance than individual vitamin D metabolites. In older adults, VMR showed a significant inverse association with parathyroid hormone and identified individuals at highest risk of all-cause mortality. In adolescents, while vitamin D deficiency was highly prevalent, VMR provided additional functional insight, showing sex-specific associations with biochemical osteomalacia, calcium status, and dietary calcium intake. Notably, VMR was linked to insulin sensitivity and metabolic syndrome in boys, independent of traditional markers, while no comparable associations were observed in girls, highlighting sexual dimorphism in vitamin D metabolism. Collectively, these findings position VMR as a functional, context-dependent biomarker that integrates vitamin D metabolism with endocrine, skeletal, and cardiometabolic health. Incorporating VMR into clinical and population research may improve risk stratification beyond 25(OH)D alone and inform more precise, sex-specific approaches to vitamin D–related health outcomes.

NSS64

THE IMPORTANCE OF BONE HEALTH MONITORING AND FRACTURE RISK PREDICTION IN INTELLECTUAL DISABILITY: STATE OF THE ART

E. Burke[1], A. Power[2]

[1]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland; [2]Wexford Intellectual Disability Services, Wexford, Ireland

Background

Osteoporosis is common among adults with intellectual disability and often underdiagnosed due to inequities in access to screening. Despite multiple risk factors including medication use, mobility difficulties, and comorbidities often times standard diagnostic pathways, such as dual-energy X-ray absorptiometry (DXA) are not always feasible leaving individuals susceptible to increased risk of fracture and deleterious consequences impacting on their mobility and independence.

Methods

This longitudinal study analysed data across the Intellectual Disability Supplement to the Irish Longitudinal Study on Ageing (IDS-TILDA). Data included participants across 15 years (N=753 2007 {wave 1) to N=762, 2023 (wave 5)]. Outcomes examined doctor-diagnosed osteoporosis, objectively measured bone quality, DXA attendance, fracture history, and factors influencing screening access.

Findings

Doctor-diagnosed osteoporosis increased from 8.1% in wave 1 to 19% in wave 5. However, over 32% were identified with osteoporosis with a further 29.4% within the osteopenic category. Over 60% of participants reported they did not access bone health assessment (DXA) despite multiple risks. Inequity of access and lack of reasonable adjustments were among the main reasons for lack of access to DXA.

Discussion

The discordance between those with a doctor's diagnosis and those objectively identified indicates a high prevalence of missed diagnosis. Overall, these levels of poor bone quality imply compromised bone integrity and an increased risk of fracture. Lack of accessible alternative bone screening increases the overall risk of fracture and subsequent quality of life issues emphasising the importance of ensure bone health screening to avoid these consequences.

NSS65

REMS APPLICATION IN INDIVIDUALS WITH INTELLECTUAL DISABILITY

F. Saponaro[1]

[1]Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa, Italy

Background

Osteoporosis remains a critical health concern within populations with intellectual disabilities, particularly due to their increased susceptibility to fragility fractures, which negatively impact quality of life and elevate healthcare burdens. Traditional methods for bone mineral density (BMD) measurement, such as dual-energy X-ray absorptiometry (DXA), face significant limitations in access and applicability, especially in residential care settings. The emergence of radiofrequency echographic multi-spectrometry (REMS) presents an opportunity to provide effective BMD assessment without the constraints of transportation or cognitive barriers associated with DXA.

REMS has already shown significant utility in adult populations, particularly those with severe motor and intellectual disabilities (SMID) residing in long-term care facilities. A recent study involving 65 adults with SMID demonstrated that REMS successfully evaluated BMD in patients unable to undergo traditional assessments. The findings revealed low BMD across participants, with mean T-scores indicative of osteoporosis, underscoring the importance of REMS in identifying high fracture risk in this vulnerable demographic. This experience emphasizes REMS's potential in enhancing osteoporosis management among individuals with disabilities.

Methods

In our project, we focused on evaluating bone and muscle health in 50 children with cerebral palsy (CP). Building on previous insights from adult populations, we utilized REMS for BMD analysis for additional assessment, ensuring a comprehensive and safe evaluation process for this pediatric group. We measured critical parameters, including serum biomarkers of mineral metabolism, muscle sarcopenia markers such as

Irisin, and indicators of neuronal damage and inflammation.

Results

Our findings revealed significant concerns regarding bone density and muscle function within the CP group, who exhibited a higher prevalence of low BMD and an increased risk of fragility fractures. Additionally, correlations between our data and physical activity metrics from wearable sensors highlighted disparities in energy expenditure and movement patterns commonly observed in children with CP.

Conclusion

Overall, this project underscores the effectiveness of REMS in assessing BMD in children with CP, illustrating its feasibility in addressing the unique challenges faced by this population. Our results emphasize the urgent need for targeted interventions to improve bone and muscle health, ultimately aiming to enhance the quality of life and minimize fracture risk in children with cerebral palsy.

NSS66

THE GLOBAL LEADERSHIP INITIATIVE IN SARCOPENIA (GLIS): A UNIFIED DEFINITION AND DIAGNOSIS OF SARCOPENIA

B. Kirk[1,2]

[1]Department of Medicine, Melbourne Medical School, University of Melbourne, Melbourne, Australia; [2]Australian Institute for Musculoskeletal Science (AIMSS), University of Melbourne and Western Health, Victoria, Australia

Background: Age-related and disease-related muscle loss and weakness (Sarcopenia) results in poor health outcomes and monumental healthcare costs; i.e., an estimated £2.5 billion annually in UK. Since sarcopenia was defined in 1989, several different definitions have emerged that are continent specific. There has been no unified definition of sarcopenia until now. The Global Leadership Initiative in Sarcopenia (GLIS) was formed to address this issue.

Objective: This presentation will outline the background and progress of GLIS to date.

Methods: A steering committee was formed of representatives from musculoskeletal and sarcopenia societies and groups globally (Kirk et al., 2024). The full committee consisted of inviting experts from these societies and groups once approval was sought. A series of Modified Delphi studies were used to establish the conceptual and operational definitions of sarcopenia; and designated working groups were formed to establish consensus on how to identify components and outcomes of sarcopenia (e.g., tools/cutpoints for low muscle mass or tools for low quality of life).

Results: The conceptual definition of sarcopenia was published in March 2024 (Kirk et al., 2024). Key findings from 'general aspects' included that sarcopenia is a disease; from 'components' were that muscle mass, muscle strength and muscle-specific strength should be part of the definition, and that impaired physical performance is a key 'outcome'. As of January 2026, the operational definition of sarcopenia is underway by Delphi (preliminary results will be presented at the Congress). Preliminary results will also be shared from the designated working groups on muscle mass, muscle strength and health outcomes of sarcopenia (Beaudart et al 2025).

Conclusion: The GLIS represents the first of many steps to define and diagnose sarcopenia globally. GLIS will support uptake into the medical glossary and implementation into healthcare systems. In turn, GLIS will help identify sarcopenia and reduce the debilitating socioeconomic consequences of poor muscle health globally.

INTEGRATING IMAGING BIOMARKERS AND BIOCHEMICAL MARKERS OF SARCOPENIA INTO FRAILTY CARE PATHWAYS

A. Mobasheri[1,2,3,4]

[1]Research Unit of Health Sciences and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; [2]Department of Regenerative Medicine, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania; [3]Department of Joint Surgery, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [4]World Health Organization Collaborating Center for Epidemiology of Musculoskeletal Conditions and Ageing, Université de Liège, Liège, Belgium

Background: Sarcopenia is characterized by the progressive loss of

muscle mass and function and is a primary driver of frailty and increased healthcare utilization globally (1). There is a critical need for objective biochemical and imaging markers to identify at-risk individuals before functional decline becomes irreversible (2). Current diagnostic pathways often rely on physical performance, yet molecular and imaging changes frequently precede clinical symptoms (3).

Objective: This presentation will provide an updated overview of current and emerging imaging and biochemical markers of sarcopenia. The presentation will also include clinical recommendations from the International Conference on Frailty and Sarcopenia Research (ICFSR) (4). Examining how these biomarker tools can be integrated into frailty care pathways can enhance early detection, enable risk stratification, and the improve monitoring of disease progression (5).

Methods: Through a review of recent basic, translational and clinical research, this presentation will evaluate the sensitivity and specificity of various modalities, including imaging techniques like DXA, MRI, and ultrasound, alongside serum-derived biochemical markers reflecting muscle protein turnover, neuromuscular junction integrity, and systemic inflammation.

Results: Recent data suggest that combining imaging biomarkers of muscle quality with specific biochemical signatures and molecular endotypes improves predictive accuracy for frailty-related outcomes compared to functional assessments alone (6). Advances in automated MRI and ultrasound protocols may allow for more precise monitoring of muscle mass in clinical settings, providing a foundation for biomarker-guided interventions that allow for more personalized, patient-centered care in community-dwelling older adults (7). Conclusion: Integrating biochemical and imaging markers into sarcopenia and frailty research is a vital step toward bridging the gap between laboratory science and clinical care. By establishing biomarkers in care pathways, healthcare systems can better operationalize frailty research, promoting improved quality of life for vulnerable elderly populations.

TRANSLATING RESEARCH INTO SERVICE: THE "FRAILTY IN COMMUNITY" PROGRAM – FROM SCIENCE TO REAL-WORLD CARE

J. Mcswan[1]

[1]PainWISE Pty Ltd, Gold Coast, Queensland, Australia

Background: Frailty affects around one in five Australians over the age of 65 years, and is associated with reduced quality of life, resilience to acute illness and survival.[1,2] Yet is often missed as, screening is not routinely captured, with the exception of assessment for aged care services.[3,4] Internationally, pilot community-based integrated models of care show promise for managing frailty, yet evidence from the Australian primary care settings remains limited.[5,6]

Objective: This presentation demonstrates how translational science informed the development of Australia's first integrated primary care program for frail and at-risk older adults, improving function and quality of life through early identification and a structured, multidisciplinary, patient-centred approach in the community.

Methods: A prospective cohort study of elderly patients referred by their GP for pre-frailty risk enrolled in a 16–24-week multidisciplinary program. Participants received coordinated psychology, physiotherapy, exercise prescription, dietary counselling, and pharmacy services delivered via home and/or clinic settings. Frailty risk, physical function, mobility, energy levels, and quality-of-life domains (physical, social, emotional, pain) were assessed at baseline and post-intervention.

Results: There were 71 patients (58% female, mean age 80 years, range 65 to 92 years) recruited into the study. Most (61%) were engaged in the home setting, the remainder in the clinic. At baseline, the mean Edmonton score was 6.3 ± 2.8. Almost a third, 31% (22/70) of participants were pre-frail and 23% were frail (16/70) based on their Edmonton scores. A majority had below-average scores for physical functioning (66%), physical limits (65%) and energy (51%). Post-intervention, 59% demonstrated improved frailty risk scores, 19% declined, and 23% remained stable. Improvements were observed across all quality-of-life domains, including physical, social, emotional well-being and pain for a majority of participants.

Conclusion: This pilot is the first to demonstrate implementation of integrated community-based care may be able to effectively reverses functional decline and maintain independence in frail older adults. Further studies examining patient selection and intervention may help optimise and expand multidisciplinary primary care models to prevent hospitalisation and optimise health outcomes in vulnerable populations.

STRENGTHS-BASED APPROACHES TO FRAILTY IN OLDER ABORIGINAL AND TORRES STRAIT ISLANDER ADULTS IN TWO AUSTRALIA-WIDE STUDIES

J. Zanker[1]

[1]Department of Medicine and Aged Care, The Royal Melbourne Hospital, University of Melbourne, Parkville, Victoria, Australia

Background: Strengths-based approaches are holistic and draw on the strengths of people, community and culture to provide a framework for growth and thriving (Fogarty *et al* 2018). Strengths-based approaches can be applied to health challenges such as frailty, which occurs at high rates and young onset in Aboriginal and Torres Strait Islander adults (Lewis *et al* 2023). The association of strengths and frailty with important social and emotional well-being (SEWB) outcomes in older Aboriginal and Torres Strait Islander peoples has not been studied, which is a critical step to inform culturally-grounded frailty care.

Objectives: This presentation provides evidence from two National Aboriginal and Torres Strait Islander Health Surveys (NATSIHS 2018-19 and 2023-23) of adults aged 45 years and older. The findings demonstrate i) the robustness of a Frailty Index (FI) and a Strengths Index (SI) across two time points; ii) the associations of FI and SI with SEWB outcomes, and; iii) that strengths moderate the association of frailty with SEWB.

Methods:

Guided by Aboriginal and Torres Strait Islander Elders (Community knowledge holders), a 56-item FI and 48-item SI were developed. The SI comprised factors considered to enhance quality of life and social and emotional well-being (e.g. secure housing, connection to Country, etc.). A composite Strengths-Frailty Index (SFI) was derived. Descriptive statistics determined associations between demographic characteristics and FI/SI. Generalised linear models and receiver operating characteristic (ROC) curves examined associations between indices and four SEWB outcomes (vitality, low distress, positive- and emotional well-being).

Results

Data for 4,697 Aboriginal and Torres Strait Islander adults (mean ± SD 58.4 ± 9.0 years, 56% women) found both FI and SI were robust across NATSIHS studies. Strengths and frailty increased with age and women had higher levels of both than men (p<.001). High Frailty/High Strengths had stronger associations with SEWB than High Frailty/Low Strengths (OR range 1.5 to 4.1, p<.001). The SFI improved area under the curve for all SEWB outcomes compared with SI or FI alone (p<.001).

Conclusion

These studies present a novel methodology to measure strengths and build on calls from Community leaders to centre strengths in efforts toward health equity.

FRAGILITY FRACTURES IN OSTEOPOROSIS: DIAGNOSTIC LIMITATIONS AND EARLY PREVENTION STRATEGIES

E. Bischoff[1], F. Bischoff[2], N. Kirilov[3], S. Vladeva[4]

[1]Rheumazentrum Ruhrgebiet, Herne, Ruhr University, Bochum, Germany; [2]Rheumatology practice Stara Zagora, Stara Zagora, Bulgaria; [3]Department of Orthopedic and Traumatology, MBAL Dr. Georgi Stranski, Medical University of Pleven, Pleven, Bulgaria; [4]Department of Health Care, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria

Background

Fragility fractures are a major complication of osteoporosis, often occurring in the vertebrae, hip, humerus and radius. Despite their clinical significance, many fractures occur in patients with osteopenia, highlighting the limitations of current imaging methods in predicting fracture risk. This study aims to discuss the typical fracture patterns in osteoporosis, the limitations of current imaging techniques for fracture risk prediction and the importance of early detection and preventive strategies to reduce fracture incidence.

Material and Methods

We conducted a comprehensive review of 50 recent publications, focusing on common fracture sites in osteoporosis, the predictive performance of imaging techniques such as DXA and approaches for early identification of patients at high fracture risk.

Results

Vertebral, hip and distal forearm fractures are the most common osteoporotic fragility fractures. The standard method DXA, primarily assesses bone mineral density but often fails to identify patients at risk for fractures with osteopenia. Microarchitectural deterioration, bone quality changes and clinical risk factors contribute to fracture susceptibility, but they are not fully captured by conventional imaging. Early detection of high-risk individuals through combined assessment of clinical risk factors, imaging and emerging techniques can enable timely preventive interventions, including lifestyle modification, pharmacologic therapy and fall-prevention strategies.

Conclusion

Fragility fractures often occur even without a diagnosis of osteoporosis, highlighting the limitations of conventional imaging. Integrating early detection strategies with clinical risk assessment, fracture risk

assessment scores and preventive measures is essential to reduce fracture incidence and improve outcomes in osteoporosis.

Key words: fragility fractures, diagnostic, limitations, prevention strategies

NSS71

IMPROVING FRACTURE PREVENTION THROUGH ADVANCED DIAGNOSTIC TOOLS

N. Kirilov[1], M. Kovachev[1], F. Bischoff[2], S. Vladeva[3], E. Bischoff[4]

[1]Department of Orthopedic and Traumatology, MBAL Dr. Georgi Stranski, Medical University of Pleven, Pleven, Bulgaria; [2]Rheumatology practice Stara Zagora, Stara Zagora, Bulgaria; [3]Department of Health Care, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria; [4]Rheumazentrum Ruhrgebiet, Herne, Ruhr University, Bochum, Germany

Objective

Fragility fractures are a major health concern in osteoporosis, often leading to morbidity, reduced quality of life and surgical interventions. Dual-energy X-ray absorptiometry (DXA), assesses bone mineral density (BMD), but fail to capture early microarchitectural deterioration and qualitative changes in bone, which limits their ability to identify patients at high fracture risk. This review aims to explore how advanced diagnostic tools can improve fracture risk prediction and contribute to early preventive strategies, potentially reducing the need for surgical interventions.

Material and Methods

A narrative review of 65 recent studies was conducted, focusing on three main areas: the limitations of conventional imaging modalities such as DXA in accurately predicting fracture risk, the clinical performance and potential advantages of emerging techniques including REMS in assessing both bone mineral density and bone quality, and strategies for early identification of patients at high risk for fragility fractures, including assessment of clinical risk factors.

Results

Evidence shows that fragility fractures frequently occur in patients with osteopenia as assessed by DXA, highlighting the need for more sensitive assessment of bone quality. REMS, a non-ionizing, portable and operator-independent technique evaluates both BMD and bone quality through fragility score with excellent precision (RMS-CV <0.5%), enabling detection of smaller changes over shorter intervals. Early identification of high-risk patients using REMS allows timely interventions, including pharmacologic therapy and fall prevention, which can reduce severe fracturesand potentially decrease the need for surgical management. While QCT also assesses trabecular bone and avoids superficial artifacts, it involves radiation, higher cost and limited portability, whereas REMS is radiation-free and suitable for bedside use.

Conclusion(s)

Advanced diagnostic tools like REMS can overcome the limitations of conventional imaging by detecting early bone deterioration, supporting targeted preventive strategies and potentially reducing fracture incidence and surgical interventions in osteoporosis. Integration of such technologies into clinical practice may enhance fracture prevention and optimize patient care.

Key words: fracture prevention, improvement, diagnostic tools

NSS72

FRACTURE PREVENTION IN HIGH-RISK PATIENTS: THE CLINICAL ROLE OF REMS TECHNOLOGY

G. Guglielmi[1,2,3,4]

[1]Professor of Radiology; Director training program for Radiation Therapy; Director training program for Radiology Technologist; Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy; [2]Professor of Radiology Capital Medical University, Beijing, China; [3]Director, Radiology Unit "Dimiccoli" Teaching Hospital, Barletta, Italy; [4]Consultant Radiologist; "Casa Sollievo della Sofferenza" Hospital, San Giovanni Rotondo, Italy

Background

Patients with chronic kidney disease (CKD) commonly develop mineral and bone disorders (CKD-MBD), resulting in impaired bone quality and increased fracture risk. Standard diagnostic tools such as dual-energy X-ray absorptiometry (DXA) offer limited information on bone microarchitecture and can be confounded by aortic calcifications and degenerative changes, which are frequent in older and nephrology patients. Radiofrequency Echographic Multi-Spectrometry (REMS) is a radiation-free technique that assesses bone status through direct analysis of raw ultrasound signals and is gaining interest for bone fragility evaluation in nephrology settings.

Materials and Methods

Recent clinical evidence on REMS performance in osteoporosis and CKD/CKD-MBD-related bone disorders was reviewed. Comparative data versus DXA were considered, focusing on diagnostic accuracy, precision, and feasibility in complex patient groups. Practical case examples were used to illustrate how REMS may support individualized monitoring and treatment decision-making.

Results

Available data indicate that REMS may mitigate several limitations of DXA, particularly in the presence of vascular calcifications and degenerative spine disease. REMS-derived parameters show strong associations with fracture risk and may provide clinically relevant information in CKD patients, including individuals receiving dialysis.

Conclusion

REMS is a promising tool to improve bone fragility assessment not only in primary osteoporosis but also in nephrology populations that are challenging to evaluate with conventional imaging. Integrating REMS into multidisciplinary pathways (geriatrics, endocrinology, orthopedics, and nephrology) may support earlier identification, better risk stratification, and more personalized prevention strategies.

PHYSICAL PERFORMANCE MEASURES FOR THE ASSESSMENT OF FUNCTIONAL LIMITATIONS IN OLDER ADULTS WITH VERTEBRAL FRACTURES

A. Papaioannou[1,2,3]

[1]Tier 1 Canada Research Chair in Geriatric Medicine and Healthy Aging, Professor of Medicine, McMaster University (Division of Rheumatology and Geriatrics), Hamilton, Canada, [2]Executive Director of the Geras Centre for Aging Research, Hamilton Health Sciences, Fellow of the Canadian Geriatrics Society (FCGS), [3]Fellow of the American Society for Bone and Mineral Research (ASBMR), Scientific Advisor of Osteoporosis Canada and International Osteoporosis Foundation

This presentation will identify key Physical Performance Measures appropriate for assessing functional limitations in older adults with osteoporotic vertebral fractures, including when and why each measure should be selected.

NSS74

APPLYING AND INTEGRATING CLINICAL CARE PATHWAYS TO GUIDE PERSONALIZED EXERCISE PRESCRIPTIONS

B. O'Hare[1,2,3,4]

[1]MSc Rehab Science, BSc Physical Therapy, Adjunct Lecturer University of Toronto, Toronto, Canada, Instructor: MSc Physical Therapy Osteoporosis Lab, McMaster University, Toronto, Canada; [2]Osteoporosis Canada/Bone Health and Osteoporosis Foundation Bone-Fit Advisory Board, Arlington, United States; [3]Owner/Director Pro Motion Physiotherapy, Thornhill, Canada; [4]Founder/Instructor: Osteoporosis Physiotherapy: The Osteo-Circuit Method™ of Exercise and Education, Thornhill, Canada

This presentation will apply a Clinical Care Pathway to stratify patients and guide individualized exercise prescription, using Physical Performance Measure outcomes to inform decision-making and progression, and integrate reassessment, feedback, and adherence strategies into rehabilitation planning to improve functional outcomes and quality of life postvertebral fracture.

NSS75

THE ECONOMIC BURDEN OF SARCOPENIA AND ITS IMPACT ON SOCIETAL COSTS AND QUALITY OF LIFE

O. Bruyère[1]

[1]University of Liège, Liège, Belgium

Sarcopenia is an age-related muscle disease increasingly recognized as a major public health challenge due to its strong association with disability, loss of independence, and adverse health outcomes in older adults. Beyond its clinical consequences, sarcopenia generates a substantial economic burden for healthcare systems and society, which remains insufficiently documented and often underestimated in decision-making processes. This presentation will provide an overview of the current evidence on the economic burden of sarcopenia, with a particular focus on societal costs and health-related quality-of-life impacts. Direct medical costs associated with sarcopenia, including hospitalizations, rehabilitation, long-term care, and outpatient management, will be discussed alongside indirect costs related to informal caregiving, productivity losses, and social support. The importance of adopting a societal perspective to capture the full economic impact of sarcopenia will be emphasized. In addition to economic costs, sarcopenia significantly impairs quality of life through functional decline, increased risk of falls and fractures, and reduced participation in daily and social activities. The presentation will highlight how quality-of-life outcomes can be quantified and integrated into economic frameworks. By identifying key methodological challenges and evidence gaps, this talk will underline the need for robust and standardized approaches to better estimate the burden of sarcopenia and support investment in prevention and management strategies.

NSS76

ECONOMIC EVALUATION AND HTA APPROACHES TO ASSESS VALUE IN SARCOPENIA

M. Hiligsmann[1]

[1]Maastricht University, Maastricht, Netherlands

While clinical efficacy and safety remain central to healthcare decision-making, cost-effectiveness analyses and Health Technology Assessment (HTA) methodologies are increasingly essential to inform sustainable access to innovation. This lecture will explore how economic evaluation complements clinical evidence by assessing the value of interventions in relation to their costs, supporting transparent and consistent resource allocation in healthcare systems.

The presentation will provide an overview of key HTA concepts and economic evaluation methods, including cost-effectiveness, and budget impact analyses, highlighting their role across the lifecycle of health technologies. Particular emphasis will be placed on early HTA and early economic modeling, which can be applied during the research and development phase to anticipate value, identify evidence gaps, and inform research priorities before definitive clinical data are available.

Sarcopenia represents a relevant and timely case study for this discussion. Despite its high and growing burden in ageing populations, through increased risk of falls, disability, hospitalization, and loss of independence, economic evidence in sarcopenia remains limited, largely due to the lack of approved pharmacological treatments and standardized care pathways. The lecture will discuss how early economic evaluation can help characterize the potential value of emerging interventions, guide trial design, and support future reimbursement and access decisions.

NSS77

LISTENING THE VOICE OF PARTICIPANTS IN SARCOPENIA RESEARCH

C. Beaudart[1]

[1]University of Namur, Namur, Belgium

As sarcopenia research moves from disease characterization toward prevention and treatment, integrating the patient perspective has become essential to ensure that emerging interventions generate meaningful and sustainable value. This evolution reflects a broader shift in research and clinical practice toward patient-centered approaches, increasingly promoted by regulators, health technology assessment (HTA) agencies, and guideline developers. While traditional research has focused primarily on biological and functional outcomes, accumulating evidence indicates that these measures alone do not fully capture what matters most to people living with sarcopenia. Research exploring patient preferences—whether in terms of outcomes or treatment characteristics—has therefore become critical to better align interventional research with patients' expectations and real-world needs.

Within this evolving landscape, the development of a Core Outcome Set (COS) for sarcopenia represents an important methodological initiative currently underway. This work aims to systematically integrate the patient voice alongside clinical and research perspectives in order to define a minimum set of outcomes that should be consistently measured in sarcopenia studies. By ensuring that selected outcomes are both scientifically robust and meaningful to patients, the COS is expected to improve comparability across studies and strengthen the relevance of evidence generated for clinical decision-making and HTA.

This lecture will present current evidence on patient preferences in sarcopenia, highlight remaining gaps in the field, and illustrate how patient perspectives are being actively incorporated into ongoing research efforts—such as the development of the sarcopenia COS—to reinforce the quality, relevance, and value of future evidence generation.

NSS78

TRANSFORMING EPISODE ACCOUNTABILITY MODEL (TEAM): IMPACT ON ORTHOPAEDIC, SPINE, AND BONE HEALTH CLINICAL PRACTICE AND OPPORTUNITIES TO DRIVE OSTEOPOROSIS DIAGNOSIS AND TREATMENT

R. Roy[1]

[1]Chief Executive Officer, Spine Health Foundation, Reston, United States

Dr. Roy will cover the following key topics:

- The core components of the TEAM model
- Discuss its financial and clinical implications
- Provide an overview on the educational activities of SHF to help health care professionals and patients understand the need to diagnose and treat patients for underlying osteoporosis before any spine or orthopaedic surgery
- Key gaps in health care professional and patient education as highlighted in the surveys conducted by SHF
- Need to coordinate care across spine, orthopaedic, and bone health disciplines

NSS79

A SPINE SURGEON PERSPECTIVE ON THE NEED FOR SPINE AND BONE HEALTH OPTIMIZATION AND IMPLEMENTATION OF FRACTURE LIAISON SERVICE PROGRAMS

P. Anderson[1]

[1]University of Wisconsin School of Medicine; Co-Chair, Spine Health Foundation Spine & Bone Health Task Force, Madison, United States

Dr. Anderson will cover the following key topics:

- Gaps in spine surgeon awareness of the need to conduct perioperative spine health optimization before surgery as a crucial step for improving patient outcomes and reducing complications (which includes a thorough bone health assessment) given the high prevalence of osteoporosis in patients undergoing spine surgery
- Why spine surgeons should establish care pathways to systematically identify and diagnose osteoporosis in their practices (which may include the establishment of a Fracture Liaison Service program or other means to ensure patients are assessed before surgery)
- The need for vertebral compression fractures to be treated as equally aggressively as hip fractures, with medications including anabolics
- Opportunities for spine/orthopaedic surgeons to work more effectively with bone health specialists and primary care to maximize patient care and improve outcomes
- The urgent need for mandatory TEAM sites to develop robust care coordination, bone health optimization protocols, Fracture Liaison Service programs, and how to best coordinate patient care with general practitioners/primary care
- Economic and personal impact of hip and femur fractures
- Impact of using AI to more efficiently identify, diagnose, and treat patients
- Need for bone health optimization and Fracture Liaison Service programs to diagnose and treat underlying osteoporosis

NSS80

MOLECULAR MECHANISMS UNDERLYING NUTRITION AND SARCOPENIA: FROM BASIC RESEARCH TO CLINICAL IMPLICATIONS

M. Montes Resano[1,2,3]

[1]Center for Applied Medical Research, University of Navarra, Pamplona, Spain; [2]Navarrabiomed, IdiSNA, Navarra Institute for Health Research, Pamplona, Navarra, Spain; [3]Allied member of the IOF

Sarcopenia represents a critical geriatric syndrome driven by a progressive failure of skeletal muscle homeostasis, transcending simple atrophy to involve profound alterations in tissue plasticity and regenerative capacity. This lecture will provide a comprehensive review of the emerging molecular evidence underpinning muscle decline, specifically examining the cellular senescence as convergent drivers of skeletal muscle aging. We will first dissect the etiology of age-related proteostatic stress, highlighting the pivotal loss of post-transcriptional control that characterizes the aging myocyte. Particular emphasis will be placed on the dysregulation of RNA-Binding Proteins (RBPs) and aberrant alternative splicing events, which collectively impair the accurate synthesis of contractile proteins and compromise the cellular stress response. Concurrently, we will address the deleterious impact of senescent cell accumulation within the muscle niche. The lecture will elucidate how these cells, through the hyperactive Senescence-Associated Secretory Phenotype (SASP), release a chronic cascade of pro-inflammatory cytokines, chemokines, and matrix-remodeling enzymes. This paracrine signaling not only fosters a catabolic, "inflammaging" microenvironment but also induces bystander dysfunction in neighboring healthy myofibers and severely inhibits the myogenic potential of satellite cells, thereby locking skeletal muscle in a state of degenerative arrest. Bridging these fundamental discoveries with clinical application, we will discuss how a granular understanding of these pathways is reshaping risk stratification and therapeutic intervention. We will explore the potential of novel circulating biomarkers, such as specific microRNAs and SASP components, to detect pre-clinical trajectories of frailty before phenotypic onset. Furthermore, the talk will evaluate next-generation strategies that extend beyond traditional macronutrient supplementation, highlighting the role of molecular nutrition and senotherapeutics—agents capable of modulating RNA stability or attenuating senescent burden—as targeted adjuvants to exercise. Finally, we will outline a roadmap for precision medicine in gerontology, proposing that targeting these specific molecular hallmarks of aging offers the most promising avenue for personalizing prevention strategies and preserving functional independence in older adults.

NUTRITIONAL STRATEGIES FOR MANAGING SARCOPENIA

B. A. Cedeño Veloz[1,2,3,4]

[1]Navarrabiomed, IdiSNA, Navarra Institute for Health Research, Pamplona, Navarra, Spain; [2]Geriatric Department, Hospital Universitario de Navarra (HUN), Pamplona, Navarra, Spain; [3]Public University of Navarre, Av Cataluña s/n, 31006, Pamplona, Navarra, Spain; [4]Allied member of the IOF

Nutritional intervention constitutes the primary therapeutic cornerstone for counteracting sarcopenia; however, clinical efficacy is frequently compromised by suboptimal implementation and the complex pathophysiology of age-related anabolic resistance. This lecture will synthesize the current evidence base aimed at overcoming the blunted muscle protein synthetic response characteristic of aging, translating mechanistic principles into rigorous clinical protocols. We will critically examine the imperative for elevated protein intake thresholds, focusing not merely on total daily volume (>1.2–1.5 g/kg/day), but on the specific amino acid quality and kinetics required to stimulate the mTORC1 pathway. Special emphasis will be placed on the "leucine trigger" hypothesis and the necessity of achieving a per-meal protein threshold (25–30g) through pulsatile dietary distribution to maximize postprandial anabolism. Beyond proteostasis, the presentation will dissect the role of the nutritional matrix in modulating the muscle microenvironment. We will evaluate the pleiotropic effects of Vitamin D on intramyocellular Vitamin D Receptor (VDR) signaling and the utility of Omega-3 polyunsaturated fatty acids (PUFAs) in mitigating low-grade systemic inflammation and improving mitochondrial membrane fluidity. Integrating these factors, the talk will provide a structured framework for precision nutrition, moving from generic advice to phenotype-specific prescriptions. We will discuss practical algorithms for the screening of malnutrition (using GLIM criteria) and the implementation of targeted oral nutritional supplementation (ONS) within a multimodal care pathway, ensuring that dietary strategies effectively synergize with physical activity to restore functional independence in the geriatric population.

INTEGRATING NUTRITION AND EXERCISE: A SYNERGISTIC APPROACH

C. Chenhui[1,2,3]

[1]Navarrabiomed, IdiSNA, Navarra Institute for Health Research, Pamplona, Navarra, Spain; [2]Geriatric Department, Hospital Universitario de Navarra (HUN), Pamplona, Navarra, Spain; [3]Allied member of the IOF

While isolated nutritional or physical interventions offer demonstrable benefits, the effective management of sarcopenia necessitates a combinatorial approach to maximize the therapeutic window and overcome homeostatic dysregulation. This lecture will examine the physiological underpinnings of the synergistic relationship between mechanical loading and nutrient availability, moving beyond the additive model to explore the potentiating effects of multimodal therapy. We will discuss how resistance training (RT) acts as a potent "anabolic sensitizer," effectively reversing age-related anabolic resistance by priming the skeletal muscle machinery to respond to hyperaminoacidemia. The presentation will dissect the molecular crosstalk between mechanotransduction pathways and nutrient-sensing signaling—specifically the convergence on mTORC1—demonstrating how the strategic timing of protein ingestion (peri-exercise nutrition) augments amino acid uptake via exercise-induced hyperemia and transporter upregulation. Furthermore, we will address the complementary role of aerobic exercise in enhancing mitochondrial biogenesis and endothelial function, thereby improving capillary density and substrate delivery to the myocyte. Drawing from recent randomized controlled trials and meta-analyses, the lecture will quantify the superior efficacy of integrated interventions on key endpoints such as appendicular lean mass, specific force, and physical performance (e.g., SPPB scores) compared to monotherapies. Finally, we will bridge physiology with clinical pragmatism, outlining evidence-based frameworks for operationalizing these complex interventions. This includes tailoring periodized training variables and nutritional support to the severity of frailty, addressing barriers to adherence, and establishing a multimodal care pathway that ensures sustainable functional preservation in older adults

LIPOPROTEIN(A) AND DENTIN HYPERSENSITIVITY: A POTENTIAL LINK BETWEEN CARDIOVASCULAR AND OSTEOPOROTIC RISK

K. Miskic[1], V. Cosic[2], B. Miskic[3]

[1]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, Faculty of Dental Medicine and Health, Osijek, Croatia,, Osijek, Croatia; [2]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK, Croatia; [3]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK , Croatia

Background: Lipoprotein(a) [Lp(a)] is a genetically determined lipoprotein particle and an established independent cardiovascular risk factor. Increasing evidence suggests that Lp(a) may influence bone metabolism through low-grade inflammation, oxidative stress, and microvascular dysfunction. These pathophysiological pathways are relevant to both cardiovascular disease and osteoporosis. Mineralized tissues, including bone and dentin, share common mechanisms of mineralization and remodeling. Dentin hypersensitivity, characterized by short, sharp pain in response to thermal, chemical, or mechanical stimuli, is typically regarded as a local dental condition. However, due to its high tubular permeability and neural responsiveness, dentin may be particularly sensitive to systemic disturbances in mineral homeostasis and microcirculation, potentially reflecting combined cardiovascular and skeletal risk.

Objective: To investigate the association between serum lipoprotein(a) levels, bone mineral density (BMD), and graded dentin hypersensitivity, and to explore dentin hypersensitivity as a potential clinical indicator linking cardiovascular and osteoporotic risk.

Methods: This cross-sectional, hypothesis-generating study included approximately 120 adult participants, predominantly postmenopausal women, recruited from an outpatient osteoporosis clinic. Serum Lp(a) concentrations were measured and categorized as low (<30 mg/dL), moderate (30–50 mg/dL), or high (>50 mg/dL). Bone mineral density of the lumbar spine and femoral neck was assessed using dual-energy X-ray absorptiometry (DXA). Dentin hypersensitivity was evaluated using standardized air and tactile stimuli and graded according to severity: Grade 0 (no sensitivity), Grade 1 (mild, stimulus-dependent sensitivity), Grade 2 (moderate, frequent discomfort), and Grade 3 (severe daily pain). Data on age, body mass index, menopausal status, smoking, and relevant oral risk factors were collected. Statistic:Multivariate analyses were performed to assess independent associations. **Results**: A progressive decline in femoral neck BMD was observed across increasing Lp(a) categories. Participants with elevated Lp(a) levels exhibited lower BMD ranges compared with those with low Lp(a). Dentin hypersensitivity severity demonstrated a clear graded association with Lp(a). Approximately 65% of individuals with low Lp(a) reported no or mild sensitivity, whereas nearly 70% of participants with high Lp(a) experienced moderate to severe dentin hypersensitivity. Importantly, elevated Lp(a) remained independently associated with higher dentin hypersensitivity grades after adjustment for BMD and other confounding variables.

Conclusion: Elevated lipoprotein(a) levels are associated with lower bone mineral density and increased severity of dentin hypersensitivity.

These findings suggest that dentin hypersensitivity may represent a clinically observable marker reflecting shared pathophysiological mechanisms underlying cardiovascular and osteoporotic risk. The results are hypothesis-generating, and longitudinal studies are required to clarify causality and clinical relevance.

NSS84

ASSOCIATION BETWEEN LIPOPROTEIN(A), MENOPAUSE, AND CARDIOVASCULAR RISK IN WOMEN

V. Cosic[1], K. Miskic[2], B. Miskic[3]

[1]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK, Croatia; [2]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, Faculty of Dental Medicine and Health, Osijek, Croatia,, Osijek, Croatia; [3]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK , Croatia

Background: Lipoprotein(a) [Lp(a)] is an established independent cardiovascular risk factor. Menopause is associated with an increase in cardiovascular risk, but its relationship with Lp(a) levels has not been fully clarified.

Objective: To investigate the association between menopausal status and serum lipoprotein(a) levels, and to evaluate their relationship with estimated cardiovascular risk in women.

Methods: This cross-sectional, hypothesis-generating study included 148 women, with a mean age of 56.8 ± 7.4 years. Of these, 113 (76%) were postmenopausal and 35 (24%) premenopausal or perimenopausal. Age at natural menopause was recorded in postmenopausal participants. Serum Lp(a) concentrations were measured using standardized laboratory assays and analyzed as categories: <30 mg/dL, 30–50 mg/dL, and >50 mg/dL. Cardiovascular risk was estimated using the SCORE2 or SCORE2-OP algorithm, incorporating age, smoking status, systolic blood pressure, and non-HDL cholesterol. Additional variables included body mass index and the presence of cardiometabolic comorbidities. Multivariate analyses were performed to assess independent associations.

Results: The overall median Lp(a) concentration was 32 mg/dL (IQR 17–58). Postmenopausal women had higher median Lp(a) levels compared with premenopausal women (35 mg/dL vs. 24 mg/dL). Lp(a) concentrations >50 mg/dL were observed in 29% of postmenopausal and 14% of premenopausal women. Median SCORE2-estimated 10-year cardiovascular risk was 5.4% (IQR 2.9–8.7). High or very-high SCORE2 risk categories were more frequent among women with Lp(a) >50 mg/dL (approximately 38%) compared with those with Lp(a) <30 mg/dL (approximately 21%). The association between elevated Lp(a) and higher cardiovascular risk remained significant after adjustment for age and traditional risk factors.

Conclusion: Postmenopausal status is associated with higher lipoprotein(a) levels and an unfavorable cardiovascular risk profile. Elevated Lp(a) clusters with increased SCORE2-estimated cardiovascular risk, suggesting that a subset of postmenopausal women may be at greater long-term cardiometabolic and skeletal risk than estimated by traditional factors alone. Assessment of lipoprotein(a) during the menopausal transition may improve cardiovascular risk stratification. These findings are hypothesis-generating and warrant confirmation in longitudinal studies.

NSS85

THE ROLE OF LIPOPROTEIN (A) IN OSTEOPOROSIS AND ATHEROSCLEROSIS: A SHARED INFLAMMATORY PATHWAY

S. Sokolovic[1], I. Tahtovic-Sokolovic[1]

[1]Society for Osteoporosis in Federation of Bosnia and Herzegovina, Sarajevo, Bosnia & Herzegovina

Introduction: Lipoprotein(a) is a cholesterol-rich lipoprotein particle similar to LDL with an additional apolipoprotein (a) attached to apoB-100. It is mainly genetically determined with pro-atherogenic, pro-inflammatory and pro-calcific properties.

Lp(a) trigger and contribute to the chronic low grade inflammation. Elevated Lp(a) levels are a well-established risk factor for cardiovascular diseases, particularly atherosclerosis contribute to the increased risk for myocardial infarction, stroke and aortic stenosis. Lp(a) levels are regulated by estrogen and postmenopausal women have higher Lp(a). So, increased Lp(a) levels often coexists with vascular calcification, atherosclerosis and osteoporosis forming a vascular-bone axis. The recent evidence suggests a potential link between high Lp(a) levels and inflammatory pathways leading to the development of osteoporosis and accelarated atherosclerosis.

This goal of this study is to explore the clinical correlation between elevated Lp(a) levels, atherosclerosis, and osteoporosis in a cohort of patients.

Methods: A retrospective case series was conducted, examining 18 patients (12 female, 6 male) aged 47-74 years in a 2-year period. All patients had clinically diagnosed atherosclerosis (coronary artery disease, carotid artery stenosis, or peripheral vascular disease) and osteoporosis (diagnosed via dual-energy X-ray absorptiometry [DXA]). Serum Lp(a) levels, hsCRP were measured in all patients. Coronary angiography and DXA scans, were reviewed to assess the extent of atherosclerotic plaques and bone density.

Results: All patients had significantly elevated Lp(a) levels, ranging from 50 to 160 mg/dL (normal range <50 mg/dL). 14 patients (77.7%) presented with advanced atherosclerotic plaques in at least 2 vascular territories, while 4 patients (22,3%) had a history of myocardial infarction or stroke. 16 patients (88.8%) showed moderate to severe osteoporosis on DXA, with 2 patients (11.2%) had prior fragility fractures. A significant association was found between higher Lp(a) levels and both atherosclerosis and osteoporosis ($p<0.05$). The hsCRP level was mildly increased 14 patients with a average range of 2,3mg/L.

Discussion: Our case series demonstrates a elevated Lp(a) and hsCRP in the progression of atherosclerosis, and the severity of osteoporosis. The shared inflammatory pathways triggered by elevated Lp(a) may contribute to endothelial damage and bone resorption.

Conclusion: Elevated Lp(a) levels may play a significant role in the development of shared inflammatory pathways in both atherosclerosis and osteoporosis. The potential dual exist in atherosclerosis and osteoporosis in patients with high Lp(a) levels Early screening and targeted interventions could help mitigate the long-term consequences of both conditions.

NSS86

UNMET NEED: FILLING THE GAP IN TREATMENT-REFRACTORY OSTEOARTHRITIS

A. Migliore[1]

[1]UOS di Reumatologia, Ospedale S. Pietro Fatebenefratelli, Rome, Italy

Objectives To define the clinical and therapeutic unmet needs of patients with osteoarthritis (OA) who remain symptomatic despite guideline-recommended conservative and intra-articular treatments, and who are not suitable candidates for joint replacement surgery.

Material and Methods This presentation is based on evidence from international guidelines, consensus statements, and observational studies addressing real-world management of OA. Particular attention is given to treatment response to non-pharmacological strategies, pharmacological therapies, and intra-articular interventions, as well as factors influencing surgical eligibility and patient preference.

Results OA remains a leading cause of chronic pain and disability worldwide, and a substantial proportion of patients do not achieve satisfactory symptom control despite multimodal conservative management, including exercise, weight management, rehabilitation, pharmacological treatments, and intra-articular injections. In clinical practice, a relevant subgroup of patients can be defined as treatment-refractory, as they remain symptomatic despite appropriate and guideline-concordant care. For these patients, joint replacement surgery represents the definitive option for end-stage disease; however, many are not optimal surgical candidates due to young age, comorbidities, contraindications, or personal reluctance to undergo arthroplasty. As a result, these individuals often remain trapped in a prolonged therapeutic limbo, characterized by persistent pain, functional impairment, and repeated use of symptomatic treatments with limited long-term benefit.

Conclusions A clear therapeutic gap exists in OA management between conservative strategies and surgery, particularly for patients with refractory symptoms who are unable or unwilling to undergo joint replacement. Addressing this unmet need requires the identification of alternative, minimally invasive treatment options that can be integrated into patient-centred, multidisciplinary care pathways. Defining this gap is a necessary step toward the rational adoption of innovative approaches targeting pain mechanisms beyond conventional therapies.

NSS87

TECHNIQUE AND ANGIOGRAPHIC LANDMARKS OF TAE

G. Facchini[1]

[1]SC di Radiologia diagnostica e interventistica, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy

Objectives To describe the technical principles of transarterial embolization (TAE) for osteoarthritis (OA)-related pain, with a focus on angiographic anatomy and procedural landmarks essential for accurate targeting and procedural safety.

Material and Methods This abstract summarizes technical and anatomical evidence from recent angiographic studies and clinical series on TAE for knee OA. Key procedural steps, vascular access strategies, angiographic projections, and identification of pathological hypervascularization are described, together with measures aimed at minimizing non-target embolization.

Results TAE is performed through selective catheterization of periarticular arteries supplying the symptomatic joint compartment. After femoral arterial access, digital subtraction angiography is used to map the genicular arterial anatomy and to identify abnormal neovascularization, typically visualized as a focal blush corresponding to pain localization. Recognition of angiographic landmarks is essential, as genicular artery origins and branching patterns show relevant interindividual variability. The descending genicular artery, superior and inferior genicular branches, and their anastomotic networks represent key targets. Oblique angiographic projections facilitate identification of vessel origins, while selective microcatheterization allows distal positioning beyond major cutaneous branches. Cone-beam computed tomography may support confirmation of target perfusion territories. Embolization is performed using microspheres delivered under fluoroscopic control. Additional safety strategies include recognition of cutaneous branches, temporary flow reduction techniques, and avoidance of embolization in vessels supplying the skin or nerves.

Conclusions Successful TAE relies on detailed knowledge of vascular anatomy and on systematic angiographic mapping to identify pathological hypervascularization while preserving non-target tissues. Standardized recognition of angiographic landmarks and meticulous embolization technique are crucial to optimize procedural safety and reproducibility, supporting the integration of TAE as a minimally invasive option within multidisciplinary OA management pathways.

NSS88

CLINICAL EVIDENCE IN OSTEOARTHRITIS

J. Ciaffi[1]

[1]University of Bologna; IRCCS Rizzoli Orthopedic Institute, Bologna, Italy

Objectives To summarize the current clinical evidence on the efficacy and safety of transarterial embolization (TAE) for the management of knee osteoarthritis (OA)-related pain.

Material and Methods Available prospective and retrospective clinical studies, including randomized and sham-controlled trials, evaluating TAE in patients with symptomatic knee OA were reviewed. Clinical outcomes were assessed using validated pain and function measures, including visual analogue scale, Western Ontario and McMaster Universities Osteoarthritis Index, and Knee injury and Osteoarthritis Outcome Score. Safety outcomes were also examined.

Results Across published studies, TAE has demonstrated high technical success rates and consistent short- to mid-term improvements in pain and function among patients with mild to moderate knee OA. Clinically meaningful reductions in pain scores and improvements in functional outcomes are typically observed within weeks after the procedure and may persist for several months. Evidence from randomized and sham-controlled trials suggests a greater magnitude of symptom improvement in treated patients compared with controls, supporting a treatment-specific effect beyond placebo. Patients with advanced structural disease appear to derive less benefit, highlighting the importance of appropriate patient selection. Adverse events are uncommon and generally mild, most frequently consisting of transient skin discoloration or local discomfort, with serious complications rarely reported.

However, substantial heterogeneity exists across studies, limiting direct comparisons and pooled analyses.

Conclusions Current clinical evidence supports TAE as a promising minimally invasive option for selected patients with symptomatic knee OA who remain refractory to conservative and intra-articular therapies and are not optimal candidates for surgery. While available data indicate favorable short- and mid-term efficacy with an acceptable safety profile, the overall level of evidence remains limited by small sample sizes and methodological variability. Larger, well-designed multicenter trials with longer follow-up are needed to better define the durability of clinical benefit, optimize patient selection, and clarify the role of TAE within OA treatment algorithms.

NSS89
BEYOND OSTEOARTHRITIS: EXPANDING HORIZONS

F. Ursini[1]

[1]University of Bologna; IRCCS Rizzoli Orthopedic Institute, Bologna, Italy

Objectives To explore the potential role of transarterial embolization (TAE) in selected inflammatory knee conditions with persistent, localized disease activity refractory to standard treatments.

Material and Methods Clinical evidence from case reports, clinical images, and focused reviews describing the use of TAE in inflammatory knee disorders was examined. Attention was given to conditions characterized by focal synovial or perientheseal hypervascularization despite adequate systemic or local therapy.

Results Inflammatory knee conditions such as chronic synovitis, enthesitis, and crystal-induced arthritis may persist despite optimized medical management and intra-articular treatments. In these settings, inflammation is often spatially confined and associated with pathological neoangiogenesis, suggesting a potential target for embolization-based approaches. Emerging clinical experience indicates that selective genicular artery embolization may provide meaningful pain relief and functional improvement in carefully selected patients with refractory inflammatory knee involvement, including cases of residual monoarticular synovitis and focal enthesitis. Early reports in chronic tophaceous gout affecting the knee further support a precision, lesion-targeted strategy. Across available studies, TAE has shown a favorable short-term safety profile, with adverse events being uncommon and generally mild. Preliminary experience from other anatomical sites, such as ankle synovitis and refractory tendinopathies, suggests that this therapeutic concept may extend beyond the knee in selected scenarios.

Conclusions TAE represents a promising minimally invasive adjunct for patients with inflammatory knee disorders who remain symptomatic despite conventional therapies and for whom escalation of systemic treatment or surgery is not appropriate. Although current evidence is limited and exploratory, these findings support further prospective studies to define the role of TAE in inflammatory knee disease.

NSS90
OSTEOARTHRITIS. AN OLD AND COMMON DISEASE

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Osteoarthritis is the most common type of joint disease, affecting many million of individuals all over the world. It is the leading cause of chronic disability in older adults with a great cost for every economy. It maybe considered as a degenerative disorder with inflammatory components. Inflammatory components may arise from the breakdown of articular carilage in the synovial joints. Osteoarthritis is thought to involve the entire joint organ and includes the subchondral bone and the synovium. The disease causes pain of varying intensity, may cause disability and may greatly affect quality of life.

NSS91
OSTEOARTHRITIS. CLINICAL PICTURE AND PATHOPHYSIOLOGY

L. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Symptoms of osteoarthritis include deep, achy joint pain exacerbated by extensive use. This joint pain is considered a primary symptom of the disease. Reduced range of motion and crepitus may be present. Stiffness during rest may also be observed which may give rise to morning stiffness of short duration. Joint edema is also observed.

Osteoarthritis is classified as a noninflammatory arthritis characterized by the formation of new bone. However, increasing evidence has shown that inflammation occurs as cytokines and metalloproteinases are released into the joint. These agents are involved in the excessive matrix degradation that characterizes cartilage degeneration in osteoarthritis. Levels of interleukin-17 (IL-17), a proinflammatory cytokine, have been found increased in the synovium of osteoarthritis joints. Other inflammatory molecules which have been associated with osteoarthritis include 15-hydroxyeicosatetraenoic acid, prostaglandin E2, IL-1β, TNF alpha, IL-1 receptor antagonist, and uric acid. Erosion of the damaged cartilage in an osteoarthritic joint progresses until the underlying bone is exposed. Bone denuded of its protective cartilage continues to articulate with the opposing surface. Eventually, the increasing stresses exceed the biomechanical strength of the bone.

NSS92

MANAGEMENT OF OSTEOPOROSIS IN BREAST CANCER PATIENTS

Y. Athanassiou[1], I. Kostoglou-Athanassiou[2]

[1]Department of Philology, Trinity College, Dublin, Ireland;
[2]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Breast cancer continues to be the most diagnosed cancer in women from the ancient years till today. Despite improvement in survival, it is still a major cause of cancer related death. Adjuvant treatment of breast cancer is generally advocated and increases survival. Aromatase inhibitor treatment increases disease free survival and reduces recurrence. Patients should be actively screened for bone health on treatment initiation with aromatase inhibitors. Calcium and vitamin D should be used in all patients. Selective estrogen receptor modulators may be used for the management of osteoporosis in breast cancer patients. Additionally, oral bisphosphonates, denosumab or zoledronic acid should be used concurrently with aromatase inhibitors to improve bone health and reduce fractures for the whole length of aromatase inhibitor treatment in women with osteoporosis or at increased risk for the development of the disease. Alendronate may be applied successfully as it improves bone mineral density, decreases fracture risk and has been shown to increase overall survival and decrease the risk of metastatic disease in breast cancer patients.

NSS93

TREATMENT OF OSTEOARTHRITIS

N. Sarianidou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Treatment of osteoarthritis is multimodal. It involves the use of pain relieving agents as well as non-steroidal-anti-inflammatory agents. The use of intra-articular injections may be used. Recently, the application of disease modifying agents such as hydroxychloroquine has been tried. Other disease modifying agents are also tested in the treatment of osteoarthritis.

NSS94

PHYSICAL TREATMENT OF OSTEOARTHRITIS

S. Mitsoulis[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Lifestyle modification, particularly exercise and weight reduction, are core components in the management of osteoarthritis. Home based exercise programs may be used successfully. Weight reduction relieves stress in the affected joints and is effective in the treatment of osteoarthritis. Local measures may also be applied therapeutically in the affected joints. Long-term walking and resistance-training programs have been shown to slow the functional decline seen in many patients with osteoarthritis, including older patients.

NSS95

FROM POLYOSTOTIC FIBROUS DYSPLASIA TO AUTOIMMUNITY: A UNIQUE CASE OF MCCUNE-ALBRIGHT SYNDROME WITH RHEUMATOID ARTHRITIS

G. Kluwak[1]

[1]Grupo Medico Oroño, Rosario, Argentina

McCune–Albright syndrome (MAS) is a rare sporadic disorder[1], with an estimated incidence of approximately 1 in 100,000 to 1,000,000 individuals[2,3], classically defined by the triad of fibrous dysplasia, café-au-lait skin pigmentation, and endocrine hyperfunction[3]. Skeletal manifestations may progress throughout life, leading to fractures[4], deformities, pain, and significant morbidity in adulthood[5]. While endocrine abnormalities are well recognized in MAS, its association with autoimmune diseases has been rarely reported.

We present a unique case of a 44-year-old woman with long-standing MAS who subsequently developed seropositive rheumatoid arthritis. This case highlights the clinical complexity of adult MAS and raises awareness of the potential coexistence of inflammatory autoimmune disease in patients with rare skeletal disorders, underscoring the importance of a multidisciplinary approach and long-term follow-up.

HYPOPHOSPHATASIA IN 2026: UPDATE AND THERAPEUTIC OPPORTUNITIES

M. Vidal[1]

[1]Centro de Diagnóstico de Osteoporosis y Enfermedades Reumáticas (CEDOR), Lima, Peru

Hypophosphatasia (HPP) is a rare inherited metabolic bone disease caused by pathogenic variants in the *ALPL* gene, leading to reduced activity of tissue-nonspecific alkaline phosphatase (TNSALP) and defective mineralization of bone and teeth.[1,2] Accumulation of alkaline phosphatase (ALP) substrates, particularly pyridoxal-5-phosphate (PLP), interferes with normal skeletal mineralization.[1,3] The disease shows marked clinical heterogeneity, with autosomal dominant or recessive inheritance and presentations ranging from severe pediatric to mild adult-onset forms. Persistently low serum ALP with elevated substrates, together with compatible clinical and radiological findings, supports the diagnosis. Although identification of a pathogenic ALPL variant facilitates diagnostic confirmation, its absence does not exclude HPP.[4,5] Early recognition is essential to prevent fractures and dental complications. In addition to established enzyme replacement therapy with asfotase alfa, next-generation recombinant alkaline phosphatase therapies, including efzimfotase alfa and ilofotase alfa, are under clinical development and may further expand therapeutic options for HPP.[1,6-11]

SKELETAL EFFECTS OF PARATHYROID DISEASE - IMPACT OF PRIMARY HYPERPARATHYROIDISM AND HYPOPARATHYROIDISM ON BONE HEALTH

A. Khan[1]

[1]McMaster University Divisions Endocrinology and Metabolism and Geriatrics, Calcium Disorders Clinic, Hamilton, Ontario, Canada

Both PHPT and HypoPT have significant effects on skeletal health impacting bone density, microarchitecture, bone quality and bone strength. This presentation will review the effects of PHPT and HypoPT on the skeleton and also review what is known about effects on fracture risk and possible treatment strategies to improve bone quality and bone strength.

NSS98

THYROID HORMONE DEFICIENCY AND LONG TERM SKELETAL OUTCOMES: IMPACT ON BONE HEALTH AND FRACTURE RISK

A. Kubat Uzum[1]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Istanbul, Türkiye

Chondrocytes and osteoblasts are directly responsive to thyroid hormone. Thyroid hormone may affect bone metabolism in different ways: direct action on osteoclasts or by acting on osteoblasts, which in turn mediate osteoclastic bone resorption. Also thyroid-stimulating hormone (TSH) may directly effect bone metabolism by acting on TSH receptors which are located on osteoblast and osteoclast precursors. The effects of thyroid hormone on osteocyte function are unknown.

Hypothyroidism in childhood and adolescence can have more serious consequences for bone development. Thyroid hormone deficiency can lead to delayed bone age, short stature, and delayed skeletal maturation.

Early histomorphometry analysis showed that hypothyroidism results in low bone turnover with decreased osteoblastic bone formation and reduced osteoclastic activity. The prolonged bone remodeling cycle includes a longer period of secondary mineralization resulting in a net increase in bone mineralization and bone mass without a change in bone volume. These changes are very slow.

Clinical data demonstrating the skeletal outcomes of hypothyroidism in adults and long-term prospective studies demonstrating changes in bone mineral density (BMD) in untreated hypothyroid patients are very limited. Also the effects of Hashimoto thyroiditis on bone microarchitecture are studied and no difference was found in women with hypothyroid Hashimoto thyroiditis in comparison with healthy subjects. Hypothyroidism in premenopausal women was reported to have no effect on BMD.

The effect of subclinical hypothyroidism on bone mineralization and fracture susceptibility has not been studied extensively, there is no consensus on its role in osteoporosis. A meta-analysis found no association between subclinical hypothyroidism and fracture risk. However, some researchers noticed that subclinical hypothyroidism is associated with decrease in serum calcium level and low BMD. Postmenopausal women with subclinical hypothyroidism tended to have a higher risk for low-trauma hip fracture.

Although levothyroxine treatment has been associated with an increase in fractures in some studies, there have been no long-term prospective follow-up studies of patients with untreated hypothyroidism. A systematic review and meta-analysis demonstrated that there is a slight adverse effect of LT4 replacement therapy on bone and mineral metabolism in patients with overt hypothyroidism, on the other hand no effect in subclinical hypothyroid patients. It is difficult to demonstrate a significant correlation between hypothyroidism and BMD or fractures because of the small number of studies and conflicting results of clinical studies. Therefore, the bone health of patients with hypothyroidism should be evaluated and managed as the current guideline recommendations

NSS99

ENDOGENOUS AND IATROGENIC THYROID HORMONE EXCESS—IMPACT ON BONE HEALTH AND FRACTURE RISK

D. Gogas Yavuz[1]

[1]Marmara University School of Medicine, department of endocrinology and metabolism, Istanbul, Türkiye

Thyroid hormone excess is a clinically important and potentially preventable contributor to secondary osteoporosis and fractures. In overt hyperthyroidism, accelerated bone turnover—driven mainly by increased resorption—leads to loss of bone mineral density (BMD) and higher fracture risk. Following restoration of euthyroid state, bone turnover markers usually decline and BMD may partially recover; however, fracture risk can remain elevated in high-risk individuals.

Iatrogenic thyroid hormone exposure also requires careful attention. When levothyroxine (LT4) is used as physiologic replacement and TSH is maintained within the reference range, long-term skeletal effects are inconsistent across studies, with variable findings for bone turnover markers and site-specific BMD. In contrast, LT4 suppressive therapy—most commonly used in differentiated thyroid cancer—is a recognized setting in which chronic TSH suppression may adversely affect bone, particularly in vulnerable groups such as postmenopausal women and patients with additional risk factors. In thyroid cancer survivors, the clinical priority is to balance oncologic benefit with skeletal safety by individualizing the intensity and duration of TSH suppression according to recurrence risk and response to therapy, while proactively preventing and treating osteoporosis when indicated.

Subclinical hyperthyroidism, whether endogenous or iatrogenic, is also associated with clinically meaningful skeletal consequences, especially in postmenopausal women. Bone loss is often more evident at cortical-rich sites, and fracture risk appears to increase in proportion to the degree and duration of TSH suppression. Management should focus on correcting the underlying cause when feasible and applying a structured fracture-risk assessment, particularly in older adults, those using glucocorticoids, individuals with low baseline BMD, or patients with prior fragility fractures.

A practical approach includes evaluating baseline fracture risk (history, clinical factors, and DXA when appropriate), ensuring adequate calcium and vitamin D intake, addressing falls risk, and initiating osteoporosis pharmacotherapy promptly in those at high fracture risk.

NSS100

FACTORS AFFECTING HIP FRACTURE SERVICE IMPLEMENTATION IN SOUTH AFRICA

S. Drew[1]

[1]University of Bristol, Bristol, United Kingdom

Implementing hip fracture services in low- and middle-income countries like South Africa is challenging. Reasons include the limited availability of staff and resources. These challenges necessitate the development of feasible, context-specific implementation strategies that leverage existing resources and infrastructure. To develop such strategies, there is a need to understand factors that help or hinder the implementation of care pathways. In this study, we explored factors influencing hip fracture service implementation in South Africa using ethnographic methods, including clinical observations and interviews with 40 healthcare professionals across six hospitals in Gauteng Province. In this talk, I will share key factors that impacted implementation from the perspective of healthcare professionals. I will discuss models of multidisciplinary teamwork, communication strategies and the challenges of balancing competing surgical priorities such as trauma from road traffic accidents. I will also examine the complex dynamics between professional groups with differing priorities, how teams worked around resource constraints to deliver care and suggestions forimproving monitoring and evaluation processes. These findings present practical opportunities to improve service delivery and develop context-specific models of care.

NSS101

HIP FRACTURE CARE PATHWAYS AND THE DELIVERY OF TRADITIONAL BONE SETTER TREATMENT IN THE GAMBIA

K. Ward[1]

[1]MRC Lifecourse Epidemiology, Southampton, United Kingdom

Globally, surgical fixation is the global gold standard of care for hip fractures, yet in The Gambia, traditional bone setters remain the preferred pathway of care despite concerns about complications. The World Health Organization's Traditional Medicine Strategy promotes integrating safe and effective traditional practices into health systems. Achieving this in the context of hip fracture care in The Gambia requires insights into patient decision-making about treatment and the relationship between traditional bone setter practices and biomedical care. In this study, we

identified factors influencing hip fracture patients' decisions to choose traditional care or biomedical services. Additionally, we described traditional bone setter treatment and explored how these practices intersect with formal orthopaedic care. We conducted ethnographic case studies to map patient care pathways, including interviews with 38 patients and their caregivers and observations of care. Additional in-depth interviews and observations of practice were carried out with 16 traditional bone setters and 38 healthcare professionals involved in hip fracture management.

In this talk, I will outline how patients navigated between biomedical care and traditional bone setter treatment, highlighting key factors that influenced decision-making such as the interpretation of injury, financial considerations and tradition. I will describe traditional bone setter techniques—including methods to identify fractures, palpation and massaging of the injury, splinting and patient immobilisation—and discuss informal referral pathways.

Finally, I will share perspectives from traditional bone setters and healthcare professionals on strategies for future collaboration. Findings highlight the potential to develop interventions to strengthen collaboration between the two sectors, helping patients better navigate complex care pathways and improving hip fracture outcomes.

NSS102

PATIENT PRIORITIES IN HIP FRACTURE MANAGEMENT AND HEALTH SYSTEM FACTORS THAT IMPACT RESPONSIVE CARE IN ZIMBABWE

C. Gregson[1]

[1]University of Bristol, Bristol, United Kingdom

Health system responsiveness refers to how well a health system meets patients' non-clinical needs and expectations—such as dignity, confidentiality, and choice of provider. Understanding what responsive care means to hip fracture patients and how healthcare professionals can meet these needs provides information that can be used strengthen services and improve patient engagement and trust. This study aimed to identify the priorities and expectations of hip fracture patients in Zimbabwe and to explore health system factors that shaped the ability of healthcare professionals to respond to these needs. Using ethnographic methods, in this study, we conducted interviews and observations with 40 hip fracture patients in Zimbabwe to examine their needs and priorities. Interviews with 42 healthcare professionals further identified the health system factors impacting responsive hip fracture care. In this talk, I will describe patients' careexperiences which highlight their need for timely access to surgery and pain relief medication, dignified continence management, appropriate communication on diagnosis and treatment and, particularly for rural-dwelling patient, access to social support. I will then outline how resources constraints, understaffing issues, and changes in Zimbabwe's pain management process impacted healthcare professionals' ability to respond to patients'needs. Finally, I will share the actions healthcare professionals' employed to circumvent health system constraints and respond to patient priorities. These insights are vital for informing the development of practical, context-specific initiatives for improving responsive hip fracture care in Zimbabwe.

Conclusion

In conclusion we will together reflect on the similarities and differences in hip fracture care across these three diverse African contexts, and consider potential policy and practice implications.

IMPORTANCE OF DIFFERENTIATED FALL RISK ASSESSMENT BETWEEN OUTPATIENTS AND INSTITUTIONALIZED PATIENTS

O. De Matos[1]

[1]Postgraduate Program in Physical Education and Health, Federal University of Technology, Curitiba, Parana, Brazil

Osteoporosis is an external manifestation of frailty in the elderly, characterized as an aging syndrome followed by the progressive loss of muscle mass and strength. The decrease in neuromuscular function increases the risk of falls and subsequent fractures, which are exacerbated in people with osteoporosis. These problems result in physical disabilities, reducing the quality of life of the older people.

A short multicomponent protocol was developed for outpatients to assess the risk of falls and fractures in frail or pre-frail elderly people through body composition, bone densitometry, muscle quality, physical performance, sleep quality and nutritional profile.

The approach to the main elements analyzed by this protocol will be the focus of this lecture, and it will highlight the comparative difference with the approach proposed for institutionalized patients.

TOPICS:

- Aging process
- Falls and fractures in older people
- Risk assessment tools
- Multidimensional assessment of the risk of falls and fractures in the older people: a follow-up study in healthcare units
- Sleep disorders assessment and diagnosis

NSS104

FALL RISK ASSESSMENT AND PREVENTION PROGRAM IN NURSING HOMES

A. L. Coutinho[1]

[1]Postgraduate Program in Physical Education and Health, Federal University of Technology, Curitiba, Parana, Brazil

In institutionalized residents, falls are associated with increased morbidity and mortality rates, a greater degree of functional dependence, and frequent use of health services. Several factors have been identified as determinants of falls, including cognitive and motor impairment, decreased muscle strength, and changes in postural balance.

This presentation aims to analyze the main differences in the methodology for assessing the risk of falls in institutionalized elderly individuals with greater cognitive and motor frailty.

Therefore, with the approach of methodology applied to outpatients, the discussion will allow for a broad view of the topic and a more detailed

analysis of the complexity of applying protocols in different populations.

TOPICS:

- Characteristics of institutionalized older adults
- Differences between institutionalized and community-dwelling older adults
- Cognitive and motor balance assessment tools
- Frailty, cognition and dual-task performance
- Main findings
- Multitask exercise program

NSS105

STANDARDIZING THE MEASURE OF MOVING, THINKING, AND FEELING: VALIDATING ASSESSMENT TOOLS FOR THE FIVE DOMAINS OF INTRINSIC CAPACITY

N. Gadallah[1]

[1]Prof. Rheumatology and Rehabilitation Ain Shams University, Cairo, Egypt

The World Health Organization has proposed a model of healthy aging built around the concept of functional ability, comprising an individual's intrinsic capacity (IC), the physical and social environment they occupy, and interactions between the two.

The foundational challenges of measuring IC lie in the validity, feasibility, and standardization of tools across the five domains (locomotor, cognitive, sensory, psychological, vitality). Key issues include heterogeneity of populations, lack of universally accepted measures, cultural/contextual differences, and balancing clinical practicality with scientific rigor.

Recent studies validating assessment tools for the five domains of IC show promising progress but highlight ongoing challenges in standardization. One is related to the overlap between domains, for example cognitive decline may affect locomotor performance, while sensory loss can influence psychological well-being, complicating domain-specific measurement.

Another one is how to align the proposed construct with related theories and approaches, notably frailty, biological age, and geroscience. Other challenges include lack of consensus on scoring methods, the need for cross-cultural validation and more integration into clinical practice.

NSS106

THE INTRINSIC CAPACITY PROGNOSTICATOR: USING INTRINSIC CAPACITY PROFILES TO STRATIFY RISK FOR FRAILTY, HOSPITALIZATION, AND NEGATIVE HEALTH OUTCOMES

M. Hassan Abu Zaid[1]

[1]Prof. Rheumatology and Rehabilitation Tanta University, Tanta, Egypt

In an era of rapid population aging, shifting from a disease-centric to a function-centric model of care is essential for promoting healthy longevity. Intrinsic Capacity (IC), defined by the World Health Organization as the composite of all physical and mental capacities an individual can draw upon, emerges as a powerful multidimensional biomarker for healthy aging. This presentation introduces the **Intrinsic Capacity Prognosticator**, a validated framework designed to move beyond simple diagnosis toward robust risk stratification for adverse clinical events.

The prognosticator utilizes comprehensive IC profiles across five core domains:

- **Locomotor & Sensory:** Assessing gait speed and sensory health as primary predictors of mobility loss and falls.
- **Cognitive & Psychological:** Identifying subclinical impairments in memory and mood that serve as early warnings for frailty and social withdrawal.
- **Vitality:** Monitoring nutritional and metabolic markers that reflect the body's physiological reserves.

By integrating these domains into a unified risk score, the IC Prognosticator demonstrates superior predictive power compared to traditional chronological age or single-disease markers. Large-scale longitudinal data indicate that individuals with low-capacity profiles are at a significantly higher risk for hospitalization, incident frailty, and long-term disability.

This data-driven approach allows healthcare providers to implement personalized risk stratification, moving from "reactive" treatment to "proactive" prevention. By identifying high-risk profiles before catastrophic health events occur, the IC Prognosticator enables clinicians to tailor multidisciplinary interventions—ranging from targeted physical therapy to nutritional support—effectively intercepting the transition from robust aging to dependency.

NSS107

FROM CONCEPT TO CLINIC: IMPLEMENTING MULTIDOMAIN, PERSONALIZED INTERVENTIONS BASED ON INTRINSIC CAPACITY IN REAL-WORLD PRIMARY CARE SETTINGS

Y. El Miedany[1]

[1]Prof. Rheumatology and Rehabilitation Ain Shams University, Cairo, Egypt

Background: As global populations age, the clinical focus is shifting from a purely disease-centric model to a functional approach centered on Intrinsic Capacity (IC). While the WHO Integrated Care for Older People (ICOPE) framework establishes IC as a composite of physical and mental reserves, practical implementation within the constraints of real-world primary care remains a challenge. This presentation explores the transition from theoretical IC conceptualization to the delivery of purposeful, multidomain interventions.

This presentation will report the systematic implementation strategy designed to integrate IC screening and personalized care planning into primary care workflows. The framework utilizes a multi-phase approach: (1) baseline IC screening across five key domains (locomotor, sensory, cognitive, psychological, and vitality); (2) the use of digital decision aids to manage treatment trade-offs (e.g., comorbidities, management of sarcopenia and increased falls risk); and (3) the co-design of "Purposeful Shared Decision-Making" tools with patients and caregivers.

Preliminary findings indicate that shifting to an IC-based model enhances the detection of subclinical functional decline that traditional disease-specific metrics often overlook. By framing clinical decisions—such as bone health management or exercise program—within the context of a patient's "functional reserve," higher rates of patient engagement and adherence were achieved. Furthermore, the implementation of standardized IC navigators reduced "fragmented care" by providing a holistic functional map used by multidisciplinary teams.

In summary, the "Function over Disease" Shift, emphasize that IC is the best predictor of healthy aging. Implementing IC in standard care is feasible and provides a more accurate reflection of an older adult's health status than comorbidity counts alone. Moving "from concept to clinic" requires the adoption of personalized navigators that translate functional data into actionable clinical decisions. This shift empowers clinicians to protect a patient's intrinsic capacity, ultimately promoting healthy aging and maintaining independence in the community.

NSS108

DYNAPENIA AND FRACTURES

A. Navarro Sotelo[1]

[1]Instituto Mexicano del Seguro Social, Hospital Aranda de la Parra, Leon, Mexico

Osteoporosis related fractures are an important medical condition worldwide, particularly in the elderly, and the incidence of hip fractures is expected to increase particularly in those low- and middle-income countries (1).

Osteoporosis is a condition of low bone mass and micro-architectural deterioration of bone, on thew other hand, sarcopenia is the loss of muscle mass, strength and function, and it is related to adverse outcomes, including risk of falls and fractures. Osteosarcopenia describes the existence of osteoporosis and sarcopenia associated with ageing (2). Some have stated that when evaluating fracture risk hand grip strength (HGS) should be evaluated altogether with bone mineral density (BMD). They found that low HGS is related to mortality on a 19 year follow up even after adjusting for age, gender, smoking, education, and physical activity (3)

HGS has been described to be an easy, accessible, cheap and helpful tool to identify those patients with osteoporosis an it´s consequences (4). There is growing evidence that HGS measurement i is related to BMD as well as fractures, including secondary fractures (5)

There is also strong evidence that low HGS in those with hip fracture is related to several complications, including pressure ulcers incidence (6), and increased mortality within the next year after the fracture occurred, in both genders, but being this more predictive among male (7).

Therefore, we conclude that HGS should be used on every clinic where osteoporosis patients are treated, unfortunately in many places they do not have access to the equipment to have this measurement done, pushing to seek for easier, yet. predictive tools in those patients.

OHAT: THE FACTS

J. L. A. Morales-Torres[1]

[1]Morales Vargas Centro de Investigación and Hospital Aranda de la Parra, León, Mexico

Oral health problems such as untreated dental caries, periodontal disease, anodontia and others, affect half of the world's population1. World Health Organization´s (WHO) Global Report on oral health, insists on their coincidences with non-communicable pathologies, pointing out the negligent attitude of health policy makers, who leave oral health out of the umbrella of universal health care1. A NICE guideline describes the need to improve collaboration of the Primary Care Physician (PCP) with Dentists2, as the average physician feels limited to identify oral problems3. Expert voices call on PCP to develop skills for detection and referral of problems like periodontitis, known for its associations with various chronic-degenerative diseases4.

The Oral Health Assessment Tool (OHAT) is a simple and reliable instrument in the detection of dental problems in a wide variety of subjects5. It could be a strong instrument for clinicians to identify and refer for proper treatment, patients with oral and dental problems. This may have a positive impact on diverse health outcomes. This presentation will examine the potential and the challenges of a deeper involvement of health professionals with oral health.

NSS110

DYNAPENIA (HGS) VS. OHAT, THE TRIAL

H. Gutierrez Hermosillo[1]

[1]Escuela Nacional de Estudios Superiores, Unidad León, UNAM, Hospital Aranda de la Parra, Leon, Mexico

Osteoporosis related fractures are a global concern due to the high burden of morbidity and mortality, and the number is increasing worldwide; hip fractures are associated to high mortality during the first year, with one third of those never recovering their functional status previous to the fracture [1,2].

There is growing evidence that oral frailty has been linked to physical frailty but as stated by Sakurai R. et al, this could be a risk factor, but could also be a consequence of physical frailty[3], or even more, from our perspective it could be a vicious circle where it is difficult to identify which came first. Oral Health Assestment Tool (OHAT) has shown to be an effective instrument identifying oral problems[4]. We have previously shown that the hand grip strength (HGS) is an easy, valuable tool identifying those patients at high risk for mortality and other complications after hip fracture[5,6], being the association more pronounced in men than in women[7].

We therefore hypothesized that those with high OHAT score could also be related to adverse events after hip fracture, thus we are carrying out a prospective cohort study, where the primary objective is to compare the effectiveness of OHAT vs HGS to identify complications after hip fracture patients. We identify patients at emergency room arrival, and previous informed consent (either provided by the patient or, in case of dementia, the caregiver) , those patients with hip fracture confirmed by the orthopedic surgeon, are included in the study, besides of the regular approach they have, HGS was measured with a hydraulic Jamar dynamometer, and OHAT is applied to each patient, all laboratory results prior surgery are recorded, they will be followed up at 1 and 12 months after surgery and compare the effectiveness of OHAV vs. HGS to predict complications including mortality, here we present preliminary results.

NSS111

THE ROLE OF QUANTITATIVE ULTRASOUND IN BONE HEALTH ASSESSMENT: A HISTORICAL OVERVIEW

R. Eastell[1]

[1]University of Sheffield, Sheffield, United Kingdom

Background: For decades, dual-energy x-ray absorptiometry (DXA) has served as the gold standard for diagnosing osteoporosis. However, the search for radiation-free, portable, and cost-effective alternatives led to the development of quantitative ultrasound (QUS). Unlike DXA, which measures mineral density, QUS was conceptualised to capture "bone quality," offering insights into microarchitecture and biomechanical properties such as elasticity.

Methodological Evolution: The foundation of QUS lies in two primary parameters: broadband ultrasound attenuation (BUA) and speed of sound (SOS). The clinical journey began in 1984 when Langton[1] et al. introduced the first application of BUA at the calcaneus. The heel was selected due to its high trabecular content and easy accessibility. This breakthrough paved the way for commercial devices in the 1990s, including the Lunar Achilles and Hologic Sahara, shifting QUS from an experimental tool to a more widely-used clinical modality. Subsequent innovations expanded the technology to peripheral sites, including the radius (UltraScan 650), fingers, and multi-site assessment (Omnisense 7000S).

Evidence and Clinical Utility: Major prospective studies, such as the EPIDOS[2] and SOF studies[3], provided crucial validation, demonstrating that QUS can predict hip fracture risk independently of bone mineral density (BMD). The OPUS study[4] further evaluated a range of devices (e.g., UBIS 5000, DBM Sonic 1200, DTU-one, QUS-2, Achilles+) and confirmed the technology's efficacy. However, the "Black Box" problem—whereby different manufacturers utilised proprietary algorithms—created challenges in standardising results across devices.

Critical Perspective: Despite its advantages in portability and the absence of ionising radiation, QUS faced hurdles in achieving dominance over DXA. The lack of standardised T-score thresholds, limited utility in monitoring treatment response, and device-specific variability hindered its integration into formal diagnostic guidelines. Consequently, DXA remained the primary tool for treatment monitoring and standardised diagnosis.

Conclusion: QUS remains a vital complementary tool rather than a direct replacement for DXA. It excels in low-resource settings, community screening, and large population studies where portability is paramount. By providing a relatively-inexpensive, radiation-free assessment of bone quality, QUS continues to offer "the right tool for the right context."

ULTRASOUND FOR FRACTURE PREDICTION

J.-G. Minonzio[1]

[1]Escuela de Ingeniería Informática, Universidad de Valparaíso, Valparaíso, Chile

Since the 1980's, Quantitative UltraSound (QUS) techniques have presented a significant interest for fragility fracture prediction, due to their non-ionizing nature, their sensitivity to structural and mechanical properties and their portability. Even though the initially introduced for clinical measurements, i.e., Broadband Ultrasonic Attenuation (BUA) and Speed of Sound (SOS) measured at the heel, and the velocity of the first arriving signal (VFAS), measured at the forearm or leg, showed strong evidence and performance comparable to the gold standard DXA, QUS was not yet widely accepted and recognized as standard-of-care in clinical guidelines, partly due to limited clinical evidence, but also because early QUS technologies have been considered to be poorly standardized, user-dependent, and difficult to interpret. This talk reviews the recognition of existing QUS technologies by well-acknowledged international clinical society, summarizes evidence of classical QUS technologies for fracture risk prediction and introduces the physical foundations of emerging techniques, i.e. pulse echo ultrasound (PEUS) [1], Radiofrequency Echographic Multi Spectrometry (REMS) [2], BiDirectional Axial Transmission with Guided Wave Dispersion Analysis (BDAT-GWDA) [3], and Cortical BackScattering (CortBS) [4]. While the two first techniques mainly propose DXA surrogates from ultrasound data measures at leg (PEUS), hip and spine (REMS), the two others (BDAT-GWDA, CortBS) are based on physical modelling and provide interpretable micro-and macrostructural bone properties, such as intracortical pore size distribution, pore density, porosity and cortical thickness. All these techniques have shown fracture discrimination performances comparable to DXA in clinical studies. Part of the future success of the implementation of these approaches will depend on the transparency of utilized algorithms, standardization, comparability between devices and the indisputable additional value to age and anthropometric data in the fracture risk evaluation, to be demonstrated in prospective clinical trials.

NEW APPROACHES AND MEASUREMENT TECHNIQUES

K. Raum[1]

[1]Charité-Universitätsmedizin Berlin, Berlin, Germany

Dual-energy X-ray absorptiometry (DXA) is the clinical gold standard for assessing fracture risk through the measurement of areal bone mineral density (*aBMD*) at central sites (spine, proximal femur). However, DXA underrepresents cortical bone loss and microstructural deterioration that accounts for most bone loss in older adults. For example, cortical thinning and increased intracortical porosity in long bones are major determinants of bone fragility (1, 2), which are poorly captured by DXA. Tissue remodeling is a key feature of bone tissue to maintain skeletal integrity, occurs at the microscopic length scale and cannot be analyzed by conventional imaging technologies. A new generation of Quantitative Ultrasound Imaging of Bone (QUSIB) technologies has been established during the past years to overcome limitations of first-generation bone QUS with the aim of directly quantifying multiple cortical bone biomarkers associated with skeletal health (3). QUSIB employs sophisticated 2D or 3D high-resolution ultrasound imaging guidance, refraction corrected image reconstruction and model-based spectral analysis of signals backscattered from intracortical pores (CortBS) to estimate cortical microstructure and viscoelastic material properties, resolving pore sizes down to approximately 20 µm.

The talk will compare the physical principles, measurement regions, and parameters measured by established QUS and novel QUSIB technologies, will summarize hopes and promises, fracture-discrimination performance compared with DXA (4, 5) and HR-pQCT, and highlight strengths, clinical findings, limitations, and clinical translation considerations (6).

In summary novel QUSIB methods represent promising, non-ionizing approaches to quantify cortical microstructure and material properties at an accessible site, with potential to improve fracture prediction beyond aBMD. Transparency with respect to measurement and analysis algorithms, reference data, as well as clinical validation in independent prospective studies using incident fractures as endpoints and broader validation across populations are required for clinical adoption.

BREAST CANCER AND BONE METABOLISM

L. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Breast cancer is one of the most common forms of cancer which affects female patients. The disease is currently treated multimodally and survival rates increase. In modern times the disease may be cured if detected on time and treated accordingly. Breast cancer is treated via surgery, i.e. the cancer is removed surgically with or without excision of the adjacent lymph nodes. Pre-operative chemoradiotherapy may also be applied, if considered necessary. Sequentially, radiotherapy may be applied in order to treat any remaining cancer cells locally. If the patient is premenopausal menopause may be induced. Chemotherapy may also be applied. Following this type of sequential initial treatment the administration of estrogen receptor antagonists such as tamoxifen or aromatase inhibitors such as letrozole may also be used. The multimodal treatment of breast cancer may affect bone metabolism via multiple ways and may induce osteoporosis.

NSS115

BREAST CANCER AND OSTEOPOROSIS

Y. Dionyssiotis[1]

[1]Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Breast cancer may be accompanied by osteoporosis. Osteoporosis in the context of breast cancer may be associated with treatment, as breast cancer may be managed by aggressive chemotherapy and radiotherapy which can adversely affect bone metabolism or induce premature menopause. In postmenopausal female patients, breast cancer and osteoporosis are common incidents which affect quality of life. Breast cancer and osteoporosis are both dependent on estrogens. Estrogens reduce fracture risk but they increase the risk of breast cancer. Estrogen treatment is therefore contraindicated in patients with a history of breast cancer. Selective estrogen receptor modifiers (SERMs) hold a great potential in the treatment of both breast cancer and osteoporosis, as they appear to decrease both fracture risk as they have an estrogen agonist effect on bone and breast cancer risk as they have an estrogen antagonist effect on breast tissue. Bisphosphonates may also be applied in the treatment of osteoporosis in breast cancer patients. Alendronate has been shown to decrease overall survival in breast cancer patients.

NSS116

ADJUVANT TREATMENT OF BREAST CANCER AND OSTEOPOROSIS

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Adjuvant treatment of breast cancer with the administration of estrogen receptor antagonists or aromatase inhibitors has been proved effective in the long-term management of the disease. Estrogen receptor antagonists such as tamoxifen have been applied successfully in the treatment of breast cancer. Various reports have shown that the application tamoxifen in the treatment of breast cancer may prevent osteoporosis or it may induce stabilization of bone mineral density. Aromatase inhibitors are effective as adjuvant therapy for breast cancer. They are used as adjuvant treatment for postmenopausal women with estrogen-receptor-positive breast cancer. Aromatase inhibitors reduce endogenous estrogens and induce osteoporosis and arthralgias. An increased risk of bone fractures has been reported in patient with breast cancer on treatment with aromatase inhibitors. Patients on treatment with aromatase inhibitors who develop osteoporosis are at increased risk for musculoskeletal symptoms and bone fractures. The use of calcium supplementation and bisphosphonates reduces the risk of osteoporosis and musculoskeletal symptoms. Monitoring of bone mineral density is essential in the management of patients with breast cancer who receive adjuvant treatment.

NSS117

MANAGEMENT OF OSTEOARTHRITIS

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Treatment should start with acetaminophen for mild or moderate osteoarthritic pain without apparent inflammation. If the clinical response to acetaminophen is not satisfactory or if the clinical presentation of osteoarthritis is inflammatory, consider using a nonsteroidal anti-inflammatory drug. Topical non-steroidal anti-inflammatory drug preparations, particularly diclofenac, are available and may be useful.

In patients with highly resistant pain, consider the analgesic tramadol.

Hydroxychloroquine, which is approved for use in rheumatoid arthritis, has been used off-label in patients with hand osteoarthritis, on the supposition that it might help by relieving synovitis. Duloxetine, a selective serotonin-norepinephrine reuptake inhibitor may also be used to treat osteoarthritis pain. Intra-articular injections with corticosteroid or hyaluronic acid may be used.

NSS118

NON-INFECTIOUS BONE INFLAMMATION THROUGH THE AGES: ONE DISEASE, MULTIPLE FACES

F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], W. Hamdi[1]

[1] Department of Rheumatology, Kassab Institute, Faculty of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia

Sterile bone inflammation encompasses a heterogeneous spectrum of rare autoinflammatory conditions characterized by chronic non-infectious osteitis. This spectrum includes chronic nonbacterial osteomyelitis (CNO), chronic recurrent multifocal osteomyelitis (CRMO), and SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis). The coexistence of multiple terms reflects the complexity of these recently recognized entities, whose underlying mechanisms remain only partially elucidated. Despite growing awareness, misdiagnosis and diagnostic delay remain common, often leading to unnecessary diagnostic procedures, radiation exposure, or prolonged antibiotic therapies.

The pathogenesis of non-infectious bone inflammation is incompletely understood but is increasingly recognized as fundamentally autoinflammatory. A pronounced imbalance in pro- and anti-inflammatory cytokine pathways has been demonstrated (1). Neutrophil-predominant inflammatory responses, overexpression of proinflammatory cytokines such as interleukin-1β, tumor necrosis factor-α, and the IL-17 axis, as well as dysregulation of innate immune pathways, including NLRP3 inflammasome activation, have been reported (2). This inflammasome activation has further been associated with dysregulated expression of immunoregulatory cytokines (IL-10, IL-19) and with possible mutations in genes such as *FBLIM1* and *P2RX7* (1). In addition, an infectious or post-infectious etiology associated with *Propionibacterium Acnes* has been extensively debated and remains debated, notwithstanding pathogen identification in several cases (3).

As for the proposed overlap between SAPHO/CNO and spondyloarthropathies, it remains controversial, even in the presence of some shared clinical features such as psoriasis and inflammatory bowel disease.

Despite complex nomenclature and an incompletely elucidated pathogenesis, recent efforts have resulted in published diagnostic criteria for both adult and pediatric forms (4,5). CNO is commonly used as an umbrella term encompassing all forms of sterile osteitis, whereas CRMO denotes its multifocal, recurrent and severe presentation (4). SAPHO refers to bone inflammation associated with characteristic cutaneous manifestations. Although some authors reserve the term CRMO for pediatric patients and SAPHO for adults, this age-based distinction is increasingly debated. Pediatric cases fulfilling SAPHO criteria have been reported, and several studies describe a pediatric form of SAPHO syndrome, supporting the relevance of defining SAPHO based on the presence of associated skin manifestations rather than age.

Clinical presentation varies with age, although substantial overlap exists. Pediatric patients often present with insidious bone pain involving long bones or the clavicle, whereas adults more frequently exhibit anterior chest wall, spinal, or sacroiliac involvement (6).

The differential diagnosis remains challenging and includes infectious osteomyelitis, malignant bone disease, and systemic disorders such as Langerhans cell histiocytosis.

Monogenetic systemic autoinflammatory disorders with bone

involvement, including Majeed syndrome, deficiency of the interleukin-1 receptor antagonist (DIRA), and pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome, should be considered in early-onset, severe, or atypical cases (7).

A better understanding of shared mechanisms, nomenclature, and age-related manifestations within the SAPHO/CNO/CRMO spectrum is essential to improve diagnosis, classification, and therapeutic strategies.

CHRONIC NON-BACTERIAL OSTEITIS AND ITS MIMICS: IMAGING THE ENIGMA

F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], W. Hamdi[1]

[1] Department of Rheumatology, Kassab Institute, Faculty of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia

Chronic Non-bacterial Osteitis (CNO) is an uncommon bone disease whose diagnosis relies on the combination of clinical presentation and radiological findings. Imaging plays a key role in the management of CNO, enabling early detection of bone lesions, the exclusion of infectious and neoplastic mimics, and monitoring of disease activity and treatment response.

Conventional radiographs are the first line imaging tool. They are useful in the exclusion of fractures and may identify typical CNO lesions such as osteolysis, sclerosis, hyperostosis, and periosteal reaction. The most frequently affected sites include distal metaphysis, particularly of the lower limb long bones, followed by vertebras (especially thoracic), pelvic bones, chest wall bones, and the medial part of the clavicle, with the latter being considered as very suggestive of CNO [1,2]. However, radiographs have limited sensitivity and could be normal in the early stages of the disease.

Whole-body magnetic resonance imaging (MRI) is considered the gold standard for both diagnosis and the monitoring of CNO. MRI is highly sensitive and contributive in the early inflammatory changes demonstrating T2 STIR-weighted signal changes (bone marrow edema and in some cases soft tissue edema). It also allows the identification of multifocal bone lesions, a key feature of Chronic Recurrent Multifocal Osteitis (CRMO) [1]. T1-weighted sequences are particularly crucial in children and adolescents as they help the differentiation between physiological hematopoietic bone marrow (intermediate T1-weighted signal) and true inflammatory lesions (low T1-weighted signal). **T2 Dixon sequences** are increasingly used in musculoskeletal MRI, offering comparable sensitivity to T2-weighted STIR while enabling better tissue characterization and reduced acquisition time. Diffusion-weighted imaging may be indicated, mainly to exclude malignancy [3]. Although one-third of the patients present with unifocal involvement, the discovery of asymptomatic lesions is common, especially when whole-body MRI is performed [1].

Computed tomography (CT) and whole skeleton technetium-99 m bone scintigraphy are not recommended as first imaging modalities in CNO/CRMO diagnosis, particularly in pediatric population, due to radiation exposure. Nevertheless, Single-Photon Emission Computed Tomography-CT (SPECT-CT) and Positron-Emission Tomography-CT (PET/CT) with a bone-seeking radiotracer may represent reasonable alternatives in adult CNO when MRI is unavailable, inconclusive or not feasible [4,5].

Bone biopsy should be considered in litigious and challenging cases, notably in the case of unusual clinical presentation (fever, acute and rapidly progressive symptoms, weight loss of unique), markedly elevated inflammatory biomarkers or LDH levels, and atypical imaging findings (unifocal lesion, diaphysis or epiphyseal localization, purely lytic lesions without sclerosis, cortical erupting, aggressive periosteal reaction, presence of abscess, marrow replacement, or soft tissues extension). Histology typically shows non-specific inflammatory infiltrate in CNO [1].

CNO remains a diagnosis of exclusion and several potential differential diagnoses must be carefully ruled out. These include infectious osteomyelitis, notably tuberculosis and cat scratch disease (*Bartonella henselae*), malignant bone tumors (leukemia, lymphoma, osteosarcoma), and benign tumors such as osteoid osteoma. Langerhans cell histiocytosis and non-Langerhans histiocytosis may also closely mimic CNO and CRMO on imaging. Langerhans cell histiocytosis is characterized with punched-out lytic lesion without associated sclerosis, most commonly involving the skull, spine and pelvis [1]. Non-Langerhans cell histiocytosis skeletal involvement typically presents as **sclerotic or both lytic and sclerotic bone lesions,** involving the **long bones (especially diaphyseal regions), pelvis, spine, and skull [6].** Moreover, several monogenic autoinflammatory disorders can manifest with osteitis, including deficiency of the interleukin-1 receptor antagonist (DIRA) syndrome—characterized by pustular dermatosis, enlarged ribs, extensive bone involvement with multifocal osteolytic lesions, and marked periostitis, particularly of the proximal femur—Majeed syndrome, which presents with neutrophilic dermatosis and anemia, and the PAPA syndrome (pyogenic arthritis, pyoderma gangrenosum, and acne), associated with cystic acne, psoriasis, and arthritis.

In these conditions, the clinical context (skin lesions and joint involvement) along with genetic testing are useful in establishing the final diagnosis [1,2].

NSS120

TOWARDS A TAILORED THERAPEUTIC APPROACH TO SAPHO/CRMO: WHAT DOES THE FUTURE HOLD?

F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], W. Hamdi[1]

[1] Department of Rheumatology, Kassab Institute, Faculty of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia

The syndromes synovitis, acne, pustulosis, hyperostosis, and osteitis (SAPHO) and chronic recurrent multifocal osteomyelitis (CRMO) are two rare, distinct, and closely related entities within the spectrum of auto-inflammatory bone disorders. Currently, there are no standardized diagnostic or treatment protocols for SAPHO/CRMO. The existing protocols are largely empirical and based solely on case series and expert opinion. The wide disparity in clinical presentation, coupled with the absence of validated outcome measurement sets to assess disease areas and therapeutic responses, makes treatment even more challenging.

A tailored therapeutic approach to SAPHO/CRMO is currently being implemented. It involves a deeper understanding of auto-inflammatory bone disorders, focusing on molecular pathomechanisms, signaling pathways, and genetic factors, as well as specific clinical symptoms [1,2]. Consequently, the treatment landscape is continuously changing from established drugs to newly introduced ones.

Therapeutic agents are used off-label to treat SAPHO/CRMO, based on treatment approaches for conditions such as psoriasis, severe acne, palmoplantar pustulosis, juvenile/adult psoriatic arthritis and spondyloarthritis. Members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) have developed consensus treatment plans for CRMO [3], and expert consensus recommendations have been recently put forward for a well-defined management strategy for adult CNO [4].

Treatment strategy and goals include: control of pain and swelling using NSAIDs -as first-line treatment- and Corticosteroids; eradicate focal infections with the use of antibiotics -as infectious factors are incriminated-; manage disease progression with csDMARDS (Methotrexate, Sulfasalazine and less frequently Leflunomide), anti-cytokine biologics and Janus kinase inhibitors as second and third-line treatments; promoting respectively Treg cell differentiation, correcting the imbalance in IL-23/IL-17 axis, JAK/STAT pathways and suppressing the inflammatory response induced by IL-1β, IL-6 and TNFα.

There are no head-to-head comparisons among these treatments, despite current data suggesting higher remission rates in CRMO/SAPHO patients treated with TNFi than those treated with csDMARDs. However, TNFi may be associated with side effects, such as the development of psoriatic dermatoses or the recurrence of palmar pustulosis.

IL-17 inhibitors and IL-23/IL-17 inhibitors should therefore be considered when csDMARDs and TNFα prove ineffective in managing skin symptoms. JAKi has also been shown to significantly improve nail lesions and palmar pustulosis. However, the absence of published evidence regarding the use of JAK inhibitors and IL-17 inhibitors in children with CRMO precludes their current recommendation.

The favourable effects of IL-1 in alleviating joint and osteitis symptoms in SAPHO syndrome, as well as joint and skin symptoms in CRMO, are encouraging. However, the risk-benefit balance must be considered given their potential side effects [2,5].

Serum levels of IL-6 are significantly elevated in patients with SAPHO/CRMO, but current data demonstrate that Tocilizumab efficacy remain limited, although some patients' pain symptoms improved and MRI results showed relief of muscle high signal areas [2,5].

The third area of treatment goals includes bone remodeling therapy with Bisphosphonates (BP) to prevent abnormal bone metabolism resorption and reduce pro-inflammatory cytokines, addressing pain and skeletal dysfunction. Pamidronate was the most commonly used BP and appeared particularly promising, yielding rapid and durable remissions, especially in cases with spinal or mandibular involvement. Rapid response to treatment with Zoledronic acid in combination with the TNFi was also observed. Because of potential side effects and the long biological half-life of BP, their use in CRMO children is limited to refractory cases or vertebral involvement and structural damage.

Despite some reported clinical resolutions in anterior chest wall and axial skeleton involvement in SAPHO, Denosumab efficacy needs to be further elucidated [6].

Biologic and antiresorptive treatments selectively target specific immunological pathways and clinical disease phenotypes, justifying their use in combination therapy when adverse effects and patient condition, particularly among children, are taken into account.

A potential future treatment target may be based on genetic mutations, protein kinase inhibition, mast cell inhibitors, and induced alterations to the microbiome, given their involvement in bone inflammation and microbiome-related disorders such as acne and inflammatory bowel disease [7].

SAPHO/CRMO treatment has not yet been standardized, but a "treat-to-target" therapeutic strategy based on clinical and imaging features has been shown to be effective in disease management with disease control or remission in most patients.

THE BURDEN OF SHOULDER PAIN

Y. Gökçe-Kutsal[1]

[1]Hacettepe University Faculty of Medicine, Department of Physical Medicine and Rehabilitation (Retired), Ankara, Türkiye

Shoulder pain represents a major and growing global musculoskeletal health challenge, ranking as the third most common musculoskeletal complaint in primary care after low back and knee pain. Its high prevalence, tendency toward chronicity, and substantial functional and socioeconomic consequences position shoulder pain as a critical public health issue across diverse populations and healthcare systems.

Epidemiological evidence demonstrates that shoulder pain is both common and persistent. Although individual prognosis varies widely, approximately 50% of patients presenting with shoulder pain in primary care continue to report symptoms six months later, underscoring its frequent transition to chronicity. Beyond pain, affected individuals often experience significant functional limitations that interfere with work productivity, leisure activities, and social participation, frequently accompanied by psychological distress and reduced quality of life. These consequences translate into a considerable economic burden. A cost-estimation study reported a mean cost of €4,139 per patient, with indirect costs—predominantly related to sick leave—accounting for more than 80% of total expenditures.

Global population-based data confirm the widespread nature of shoulder pain but reveal substantial heterogeneity in reported prevalence and incidence. A comprehensive systematic review synthesizing data from 61 observational studies across high-, middle-, and low-income countries found that community prevalence estimates varied markedly, with a median prevalence of 16% and a wide range (0.67%–55.2%). Longer reference periods were consistently associated with higher prevalence estimates. In contrast, primary care prevalence was lower, ranging from 1.01% to 4.84%. Incidence rates varied from 7.7 to 62 cases per 1,000 person-years, with a median of 37.8 per 1,000 person-years. Shoulder pain was consistently more prevalent among women and more frequently reported in high-income countries. Importantly, variability across studies was not adequately explained by risk of bias—most studies were rated as low risk—but rather reflected differences in case definitions, reference periods, study methodologies, and population characteristics. Notably, data from low-income regions remain scarce, limiting accurate estimation of the true global burden.

From an etiological perspective, most cases of shoulder pain arise from disorders of the periarticular soft tissues or the glenohumeral and acromioclavicular joints. The most common causes include rotator cuff–related disorders (tendinopathy and tears), shoulder impingement, adhesive capsulitis, glenohumeral or acromioclavicular osteoarthritis, instability syndromes, calcific tendinitis, and bursitis. Traumatic etiologies—such as fractures and dislocations—are less frequent but clinically critical. In addition, shoulder pain may originate from cervical spine pathology, brachial plexus involvement, or referred pain from visceral conditions, including cardiopulmonary or intra-abdominal disease. This broad differential diagnosis necessitates a systematic and clinically vigilant approach.

Initial clinical evaluation should integrate a detailed history and focused physical examination, with particular attention to identifying red flags that may indicate serious underlying pathology. These include a history of significant trauma, suspected fracture or dislocation, signs of systemic infection, previous or current malignancy, unexplained weight loss, severe or progressive night pain, and evolving neurological deficits. The presence of fever, chills, night sweats, joint warmth, erythema, or acute swelling should raise suspicion for septic arthritis or osteomyelitis, particularly in immunocompromised individuals or following recent surgery or injection. Constant, non-mechanical pain unrelieved by rest—especially in patients with a history of cancer—should prompt evaluation for metastatic disease. Progressive weakness, sensory loss, or signs of cervical myelopathy warrant urgent assessment for neurological compromise. Finally, shoulder pain associated with chest pain, dyspnea, or abdominal symptoms should alert clinicians to possible referred visceral pathology.

In conclusion, shoulder pain constitutes a highly prevalent, heterogeneous, and disabling condition with profound individual and societal consequences worldwide. Addressing its global burden requires not only improved prevention and management strategies but also greater methodological standardization in epidemiological research and increased representation of low-income regions. A structured clinical approach, grounded in early recognition of red flags, remains essential to optimize outcomes and reduce the long-term impact of this common yet complex disorder.

NSS122

ASSESSMENT AND DIAGNOSTIC APPROACH OF SHOULDER PAIN

S. Gülbahar[1]

[1]Dokuz Eylül University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Izmir, Türkiye

Shoulder pain is a common musculoskeletal complaint that may be due either to intrinsic disorders of the shoulder or referred pain. The intrinsic disorders include injuries and acute or chronic degeneration or inflammation of the shoulder joint, tendons, surrounding ligaments, or periarticular structures. Therefore, the assessment and diagnostic approach for shoulder pain require a meticulous systematic integration of clinical history, physical examination, and selective imaging to differentiate between intrinsic shoulder pathology and extrinsic sources of pain.

Obtaining a detailed clinical history is essential for determining the etiology of pain and identifying "red flags" that require urgent investigation, such as malignancy, infection, or acute trauma with suspected fracture. In demographics patients' age, occupation and recreational activities and sports are very important. Age is a primary predictor for diagnosis; younger patients more frequently present with acute injuries and instability, while those older than 40 are at higher risk for rotator cuff (RC) tears, adhesive capsulitis, and osteoarthritis. Occupation and sports may also cause and exacerbate the symptoms. A standard pain history (ie, onset, duration, palliation/provocation, character, severity, location, radiation and coexisting symptoms) helps to identify diagnosis. The traumatic onset may indicate fractures or acute tears, while insidious onset repetitive motions and overuse often suggest impingement or degenerative tendinopathy. Severe pain with sudden onset may imply calcific tendinitis. The location and the character of pain are also important. While pain at the lateral deltoid is typically related to rotator cuff pathology, the anterior-superior pain often localizes to the acromioclavicular (AC) joint. Night pain is a hallmark of RC tears and adhesive capsulitis. Coexisting symptoms, such as active and passive range of motion limitation, weakness, numbness, swelling, crepitation and instability must be investigated. Comorbid conditions such as diabetes and thyroid disease have a strong association with adhesive capsulitis.

Physical examination with a structured sequence: inspection, palpation, range of motion (ROM), strength, and provocative tests must be done carefully. Clinicians should begin with inspection of skin, scars, swelling, symmetry, scapula and size. Any size alterations such as muscle atrophy (e.g., supraspinatus/infraspinatus) suggests chronic tears. And proceed with careful palpation for localized tenderness, such as over the AC joint, subacromial space or bicipital groove. A novel, simplified algorithm triages patients based on the presence or loss of ROM. Loss of active but preserved passive ROM often indicates rotator cuff pathology or tears. Loss of both active and passive ROM suggests adhesive capsulitis or glenohumeral joint osteoarthritis or dislocations. Some patients may have preserved ROM; the diagnosis is made by using specific special tests. The use of special provocative tests and their combinations to confirm or to rule out a diagnosis of tendinopathy or of full-thickness rotator cuff tears is essential. The Hawkins and Neer tests assess for subacromial impingement; the Empty Can (Jobe) test evaluates the supraspinatus; and the External Rotation Resistance test assesses the infraspinatus. Speed's and Yergason's tests are sensitive for biceps tendinopathy. The crossbody adduction (scarf) test is highly sensitive for AC joint pathology. Apprehension and relocation tests evaluate for glenohumeral instability.

Diagnostic imaging should be utilized when the diagnosis remains unclear, or the outcome would alter management. Plain radiography is the initial diagnostic modality recommended for both acute and chronic pain to delineate bony anatomy, fractures, and degenerative changes like joint space narrowing or osteophytes. Ultrasound (US) is a cost-effective tool with accuracy comparable to MRI for identifying full-thickness RC tears. It allows for dynamic assessment and is useful for detecting bursitis and calcific tendinosis. Magnetic Resonance Imaging (MRI/MRA) is indicated for complex cases, suspected labral pathology, or massive RC tears. MR arthrography is considered the gold standard for intra-articular pathology like SLAP tears. Computed Tomography (CT) is preferred for detailed evaluation of fracture patterns, glenoid bone stock in recurrent instability, and preoperative planning for joint replacement.

Clinicians must distinguish shoulder-related pain from extrinsic sources for differential diagnosis. A distinguishing characteristic of referred pain, in contrast with intrinsic shoulder problems, is that shoulder movement is normal and does not alter the character of the pain. A careful history can often distinguish between the causes of referred shoulder pain especially from visceral organs. Cervical spine pathology can mimic shoulder pain but typically radiates below the elbow and is elicited by neck movements. Other potential causes include thoracic outlet syndrome (presenting with neurovascular symptoms) and brachial neuritis (characterized by sudden, severe pain followed by weakness).

NSS123

TREATMENT PATHWAYS IN SHOULDER PAIN: PHARMACOLOGICAL MANAGEMENT

A. A. Küçükdeveci[1]

[1]Ankara University, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Türkiye

Common causes of shoulder pain, after ruling out the red flags, include rotator cuff tendinopathy or tear, adhesive capsulitis, glenohumeral or acromioclavicular osteoarthritis, glenohumeral instability, and calcific tendinitis. Goals in the management of shoulder pain is to control pain and inflammation, improve and/or preserve joint mobility, restore trunk muscle posture and scapula-humeral rhythm, increase muscular strength and endurance, and restore functioning in daily activities and social participation. The first-line therapeutic approaches generally include pharmacological treatments and physical and rehabilitation interventions. Pharmacological therapies are usually administered to reduce inflammation and pain, thereby enabling movement and rehabilitation. They must be tailored to the specific shoulder disorder and its severity as well as the age and comorbidities of the patient. They are always combined with patient education for rest and activity modification, and exercises.

Commonly prescribed and suggested first-line medical treatments in most shoulder pathologies are systemic paracetamol and non-steroidal anti-inflammatory drugs (NSAIDs). Topical NSAIDs and capsaicin can be used for superficial lesions in patients who have contra-indication for systemic NSAIDs. Short-course opioids and muscle relaxants can be prescribed for patients who have severe pain and/or sleep disturbance unresponsive to first-line medications. Subacromial corticosteroid injections are recommended for rotator cuff disease, although multiple injections are not suggested in full rotator cuff tears. Intra-articular corticosteroids are indicated for adhesive capsulitis (with or without hyrodilatation) as well as glenohumeral and acromioclavicular osteoarthritis. Subacromial corticosteroid injections and needling, as well as ultrasound-guided needle lavage, may be helpful in calcific tendinitis.

Other local medications commonly used in painful shoulder disorders are hyaluronic acid and platelet-rich plasma (PRP) injections, although there is controversy about their use in various guidelines. Some guidelines are in favor of hyaluronic acid injections in rotator cuff disease and glenohumeral osteoarthritis, whereas PRP injections are usually not

recommended. However, recent systematic reviews and meta-analyses have shown the positive effects of both hyaluronic acid and PRP injections as well as prolotherapy in rotator cuff disease. Intra-articular hyaluronic acid injections showed consistent and modest benefits on pain and function in shoulder osteoarthritis. The beneficial effects of PRP injections on pain and function in adhesive capsulitis have also been documented by recent meta-analyses.

REHABILITATION OF SHOULDER PAIN-RELATED CONDITIONS

O. El[1]

[1]Dokuz Eylül University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Izmir, Türkiye

Shoulder pain is a highly prevalent musculoskeletal condition for which clinical practice guidelines universally recommend conservative rehabilitation, particularly active exercise therapy and patient education, as the primary first-line treatment strategy prior to considering surgical interventions. There is strong consensus across clinical practice guidelines that active rehabilitation is the primary intervention for rotator cuff (RC) tendinopathy. Prescribing an exercise program is universally recommended. Recommended exercise components include range of motion (ROM), strengthening, and motor control exercises. Moderate-quality evidence indicates that both supervised and home-based exercise programs are effective in improving pain and function in the short and longterm. Patient education focusing on relative rest and activity modification is considered an essential component of rehabilitation. Manual therapy is widely supported but is generally recommended as an adjunct to exercise rather than as a standalone intervention. Evidence for physical agents and passive modalities is mixed, and several guidelines recommend against their routine use due to a lack of robust benefit compared with active therapy. There is moderate evidence supporting the effectiveness of high-energy extracorporeal shock wave therapy for calcific rotator cuff tendinitis; however, for non-calcific tendinopathy, the evidence is inconclusive or unfavorable.

Conservative rehabilitation is also a primary treatment option for most rotator cuff tears, especially degenerative tears, with outcomes often comparable to surgery in the short to medium term. Exercise prescription is universally recommended for the management of full-thickness RC tears, with programs typically including ROM and strengthening exercises. Physical therapy protocols centered on exercise have been shown to be effective for improving function. However, one high-quality study reported that although physical therapy is effective, surgical tendon repair may result in superior outcomes at long-term follow-up (approximately five years). Manual therapy is generally supported as an adjunct to exercise rather than a definitive treatment. Low- to moderate-quality evidence suggests that manipulation and mobilization may be effective for RC disorders, either alone or in combination with other therapies. Accordingly, guidelines classify manual therapy as "recommended" or "may be recommended" for full-thickness tears. Evidence supporting physical agents and passive modalities remains mixed. Although rehabilitation is the first-line approach for many patients, guidelines specify indications for surgical referral. Referral is recommended for acute traumatic full-thickness tears, especially in younger patients with significant functional impairment. Surgery is also indicated when there is no meaningful improvement after a defined period of conservative care, typically 6 to 12 weeks in some guidelines or 3 to 6 months in others.

Adhesive capsulitis is a common musculoskeletal disorder characterized by pain and progressive restriction of shoulder mobility, leading to substantial functional impairment. In primary (idiopathic) adhesive capsulitis, no underlying etiology can be identified, whereas in secondary adhesive capsulitis, an associated condition or cause is present. Rehabilitation is a core component of management, although the strength of evidence varies across interventions. Manual therapy, particularly ROM exercises, is conditionally recommended to improve shoulder mobility and upper limb function. Mobilization with movement techniques have demonstrated superiority over passive stretching for short-term pain reduction and functional improvement. Self-stretching exercises are supported by expert consensus as an adjunctive strategy, provided that patients adhere to proper technique. High-quality trials have shown that supervised physical therapy combined with a home exercise program may be similarly effective to a home exercise program alone. There is low-to moderate-quality evidence supporting the use of low-level laser therapy for pain relief and functional improvement, either as a standalone intervention or in combination with exercise, and some guidelines strongly recommend it for pain management. Transcutaneous electrical nerve stimulation may also be considered for pain relief. Evidence for deep heat therapy is insufficient or inconclusive, although some guidelines suggest it may be recommended. Injections are frequently used to facilitate rehabilitation by reducing pain and inflammation. Intra-articular corticosteroid injection is considered a cornerstone treatment and is strongly recommended to improve pain and function. Combining

corticosteroid injections with physical therapy provides greater clinical benefit than physical therapy alone. Hydrodilatation, particularly when combined with intra-articular corticosteroids, is recommended, and intensive mobilization immediately following hydrodilatation is considered a promising adjunct. Suprascapular nerve block may be considered for pain relief and has demonstrated superior pain reduction compared with physical therapy alone in some studies. Hyaluronic acid injections are generally viewed as a second-line option when corticosteroids are contraindicated or not feasible. Although frozen shoulder is often described as a self-limiting condition, not all patients experience complete spontaneous recovery, and some may develop long-term disability. This underscores the importance of active and effective management rather than a passive "wait-and-see" approach. Current guidelines indicate insufficient evidence to support manipulation under anesthesia over other treatment options. Given the associated risks, including fractures and rotator cuff tears, intra-articular corticosteroid injections should be considered before manipulation. Hydrodilatation is often preferred over manipulation due to lower cost and a reduced risk of complications. Surgical capsular release is typically reserved for patients who fail to respond to comprehensive conservative management.

NSS125

INTRODUCTION IN OSTEOSARCOPENIA AND FALLS

E. Belgin[1]

[1]İstanbul Medeniyet University, School of Medicine; PMR Department,, Istanbul, Türkiye

The term osteosarcopenia has recently been used to denote a clinical syndrome that integrates the biochemical, physiological, and clinical characteristics of osteoporosis and sarcopenia. This syndrome illustrates the intricate interconnection between bone and muscle health, wherein simultaneous deterioration of bone density and muscle mass, strength, and function results in a compounded escalation of frailty and physical susceptibility. Consequently, osteosarcopenia has become a significant factor in falls, fractures, disability, and the loss of independence in older adults. Although osteosarcopenia is increasingly acknowledged as a critical geriatric illness, data for its optimum management, especially regarding structured exercise programs, remains scarce. This disparity is significant, as exercise is universally acknowledged as fundamental to fall prevention and is recognized for its advantageous effects on bone and muscle via mechanical loading, neuromuscular adaptation, and enhancements in balance and functional performance. The recent release of the World Falls Guidelines signifies a significant advancement in evidence-based fall prevention; nonetheless, the application and execution of their proposed exercise routines for individuals with osteosarcopenia remain ambiguous. Most current exercise guidelines focus on osteoporosis or sarcopenia separately, rather than the concurrent disease that defines osteosarcopenia. Therefore, there is an urgent need for research that assesses specialized, integrated exercise programs designed for this demographic, to enhance clinical practice and refine fall prevention measures in older persons with concurrent bone and muscle deficiencies.

NSS126

EXERCISE AND FALLS: PROTOCOLS FROM WORLD FALLS GUIDELINES

M. Tsekoura[1]

[1]Physiotherapy Department, School of Health Rehabilitation Sciences, University of Patras, Rio, Greece

In persons with osteosarcopenia, exercise regimens for fall prevention must be expressly linked with the World Falls Guidelines, considering the concurrent muscle and bone pathology inherent to this illness. In osteosarcopenia, fall prevention exercises can be implemented by combining the Otago Exercise Program with the World Falls Guidelines. Otago provides a gradual balance and lower limb strengthening program that adheres to guideline specifications for personalized, appropriately calibrated therapies. Balance training is fundamental, resistance exercise addresses sarcopenic weakness and facilitates bone loading, while walking serves as an adjuvant once balance is enhanced. This integrated framework tackles simultaneous muscle and bone deficiencies, even in the lack of condition-specific guidelines. Balance-challenging exercises are the key intervention and should be administered at an adequate frequency (≥3 hours per week), incorporating gradual lowering of the base of support, dynamic weight shifting, and functional perturbations, as balance deficits are a principal contributor to falls in this demographic. Resistance and power training focused on the lower extremities are crucial to combat sarcopenic weakness and delayed force generation, and must be combined with safe, gradual mechanical loading to promote bone adaptation while minimizing fracture risk. Task-specific exercises, such as transfers, turning, and stair negotiation, are essential for improving the application of training effects to daily tasks, where falls predominantly happen. Walking independently is inadequate and may elevate the danger of falls unless accompanied by enhancements in balancing ability. Mind–body exercises like Tai Chi may be suitable for persons with mild impairment but necessitate modification for those with advanced osteosarcopenia. Exercise regimens must be tailored, progressive, and sustained, with meticulous oversight throughout initial stages to guarantee safety and compliance. The World Falls Guidelines, while not specific to osteosarcopenia, offer a systematic approach for comprehensive fall prevention strategies addressing the combined deficiencies of muscle and bone. This highlights the critical necessity for condition-specific trials to optimize dosage, progression, and safety parameters in this high-risk demographic.

NSS127

QUESTIONNAIRES AS A TOOL FOR FALLS PREVENTION IN OSTEOSARCOPENIA

Y. Dionyssiotis[1]

[1]Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

A variety of questionnaires have been created to detect older adults at risk of falling; however, none has been explicitly validated for individuals with osteosarcopenia. This signifies a significant limitation, as osteosarcopenia amalgamates the functional repercussions of both sarcopenia and osteoporosis, potentially modifying fall processes and risk profiles in comparison to either condition independently. The SARC-F questionnaire is a validated and often utilized screening

instrument for sarcopenia, incorporating a component pertaining to falls; yet its principal aim is to detect sarcopenia rather than evaluate fall risk. Thus, SARC-F is deficient in sensitivity and breadth necessary to serve as a specialized fall risk screening tool for older people with osteosarcopenia. Consequently, there is a distinct necessity to discover or modify surveys with falls as the key endpoint for this demographic. Accurate fall risk assessment is crucial for risk stratification, directing personalized rehabilitation strategies, and enhancing the selection and intensity of fall prevention measures. This part will examine current falls surveys that may effectively identify older people with osteosarcopenia at heightened risk of falling.

NSS128

DOUBLE BURDEN, SINGLE PATIENT: BARRIERS TO PHYSICAL ACTIVITY IN OLDER ADULTS WITH KNEE OSTEOARTHRITIS AND TYPE 2 DIABETES

A. Ibrahim[1]

[1]Centre for Healthy Ageing and Wellness (H-CARE), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur , Malaysia

Objective(s): To identify key behavioural and contextual barriers to self-management in older adults living with coexisting knee osteoarthritis (OA) and type 2 diabetes mellitus (T2DM), and to determine how these barriers shape engagement in physical activity and symptom management.

Material and Methods: This qualitative study involved 16 community-dwelling adults aged ≥60 years with clinically diagnosed knee OA and T2DM, recruited from community centres and primary care clinics in Kuala Lumpur and Selangor, Malaysia. Semi-structured interviews explored experiences related to pain, fatigue, physical activity, and daily management. Interviews were audio-recorded, transcribed verbatim, and analysed thematically using the Theoretical Domains Framework (TDF) to systematically identify behavioural, psychosocial, and environmental determinants.

Results: Participants (mean age 69.6 ± 5.0 years) described barriers across ten TDF domains. Central barriers included low perceived capability and motivation driven by pain, ageing, fatigue, obesity, and diabetes-related concerns, alongside limited optimism regarding exercise benefits. Structural constraints such as financial cost, transport limitations, and competing self-management demands restricted physical activity. Social influences, including lack of companionship and family discouragement, further reduced adherence. Fear of pain exacerbation or falls, emotional distress, reduced physical capacity, and low digital literacy compounded difficulties in sustaining active behaviours.

Conclusions: In older adults, the coexistence of knee OA and T2DM creates a compounded barrier profile that directly undermines physical activity and functional recovery. These findings demonstrate that standard knee OA management approaches are insufficient for individuals with diabetes. Integrated, behaviour-informed, and diabetes-sensitive musculoskeletal care models are urgently needed to address obesity, physical inactivity, and social support gaps, with clear implications for clinical practice and service design in ageing populations.

NSS129

MANAGEMENT OF KNEE OSTEOARTHRITIS IN OLDER ADULTS WITH DIABETES MELLITUS IN LOW RESOURCE SETTING: A QUALITATIVE STUDY AMONG MALAYSIAN HEALTHCARE PROVIDERS

M. Omar Abbass Alababseh[1]

[1]Centre for Healthy Ageing and Wellness (H-CARE), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur , Malaysia

Objective: To explore the barriers and enablers influencing healthcare providers' (HCPs) assessment and management of knee osteoarthritis (KOA) among adults with type 2 diabetes mellitus (T2DM) in Malaysia, guided by the Theoretical Domains Framework (TDF).

Material and Methods: Twelve semi-structured video interviews were conducted with family medicine specialists, endocrinologists, geriatricians, general practitioners, rheumatologists, and orthopedic surgeons who manage patients with KOA and T2DM across diverse Malaysian healthcare settings. Interviews lasted 30–45 minutes, were transcribed verbatim, and analyzed deductively using the TDF. Thematic analysis within each domain identified belief statements and behavioral determinants shaping clinical practice.

Results: Six major TDF domains emerged. (1) Knowledge: Participants reported limited understanding of dual-condition management and highlighted the need for structured clinical guidelines. (2) Skills: HCPs emphasized holistic, multidisciplinary care but cited difficulties coordinating between specialties. (3) Intentions: Empowering patients through shared decision-making and education was prioritized. (4) Professional Role and Identity: Primary-care physicians viewed themselves as coordinators but experienced ambiguity in inter-professional responsibilities. (5) Environmental Context and Resources: Time constraints, workforce shortages, and financial barriers hindered comprehensive care. (6) Social Influences: Patient pain, low motivation, socioeconomic challenges, and cultural norms affected adherence to treatment and lifestyle recommendations. Despite these challenges, participants endorsed the need for integrated, patient-centred management that concurrently addresses joint and metabolic health.

Conclusion: This study identifies multi-level behavioral and systemic factors affecting the management of KOA and T2DM in Malaysia. Addressing knowledge gaps, establishing clear multidisciplinary pathways, and improving resource allocation are critical to enable effective, person-centred multimorbidity care. Findings provide evidence to inform the development of integrated interventions within the i-MOAD framework.

NSS130

DEVELOPMENT OF COMPLEX INTERVENTION FOR OLDER MALAYSIANS LIVING WITH OSTEOARTHRITIS WITH DIABETES MELLITUS (I-MOAD) STUDY

S. Mat[1]

[1]Centre for Healthy Ageing and Wellness (H-CARE), Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur , Malaysia

Objective: This study aimed to design a comprehensive, theory-based intervention to assist primary healthcare providers (HCPs) in delivering integrated, patient-centred care for older adults living with knee osteoarthritis (KOA) and type 2 diabetes mellitus (T2DM) in Malaysia.

Materials and Methods: Intervention development followed the UK Medical Research Council (MRC) framework and was informed by the Theoretical Domains Framework (TDF). The process comprised four sequential phases. Initially, priority behaviours and relevant professional groups were identified through a scoping review and stakeholder engagement. Next, semi-structured interviews were undertaken with 16 adults with KOA and T2DM, 12 healthcare providers, and 12 physiotherapists to identify perceived barriers and facilitators to integrated KOA–T2DM care. Subsequently, identified behavioural determinants were systematically linked to appropriate Behaviour Change Techniques (BCTs) to inform potential intervention components. In the final phase, stakeholders assessed the proposed intervention for feasibility and acceptability using the APEASE criteria, resulting in the development of a programme theory to support implementation.

Results: Major barriers to effective care included insufficient knowledge, reduced self-efficacy, avoidance of physical activity due to pain, and contextual and environmental limitations. A total of fifteen BCTs were selected, forming a multidimensional intervention addressing KOA–T2DM management, dietary practices, and physical activity. The intervention was designed to be delivered through self-management booklets, exercise monitoring logs, and optional digital support. Stakeholder feedback indicated that the intervention was culturally appropriate, feasible to implement, and acceptable within the primary care setting.

Conclusion: The i-MOAD intervention represents a structured, theory-informed, and stakeholder-driven strategy for the integrated management of KOA and T2DM. It has the potential to enhance self-management behaviours, functional outcomes, and coordination of care within primary healthcare.

Disclosures:The authors declare no conflicts of interest.

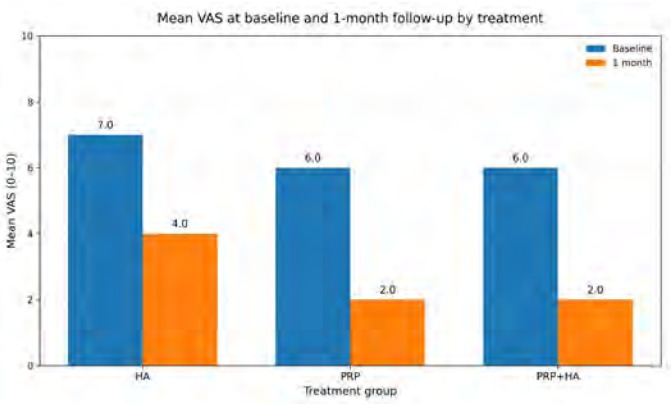
EFFECTIVENESS OF PLATELET-RICH PLASMA, HYALURONIC ACID, AND COMBINED THERAPY IN THE TREATMENT OF KNEE OSTEOARTHRITIS AS ASSESSED BY THE VISUAL ANALOGUE SCALE

A. A. Cifuentes[1], F. Rodas Flores[2], C. Brincker Nicolas[2], N. J. Gonzalez Licardie de Ancheta[2], R. J. López Méndez[2], B. Lopez Samayoa[3]



[1]Amir Wellness Center, Iniciativa Guatemalteca de Ortobiológicos y Rehabilitación (IGOBIR), Quetzaltenango, Guatemala; [2]Centro Universitario de Occidente at Universidad de San Carlos de Guatemala (USAC), Quetzaltenango, Guatemala; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Guatemalan therapeutic management of osteoarthritis (OA) patients includes analgesics and anti-inflammatories, as well as non-pharmacological interventions, such as physiotherapy and, in advanced stages, resorting to surgical procedures. The limited availability of cutting-edge therapies, such as ortho-biologics, represent a challenge in the national context.

Objective To evaluate the effectiveness of platelet-rich plasma (PRP), hyaluronic acid (HA) and their combined therapy in the treatment of knee OA, measured using the Visual Analogue Scale (VAS).

Material and Methods A cohort study was conducted including 135 patients with Kellgren–Lawrence grade I–III knee OA, selected from a population of 207 patients, calculated with a 95% confidence level. Patients were assigned into three groups: PRP (n=45), HA (n=45) and PRP+HA (n=45). Pain intensity was measured using the VAS at baseline and at days 5, 10, 15 and one month after treatment. Data from 2022–2025 were analyzed using one-way ANOVA and Tukey HSD tests.

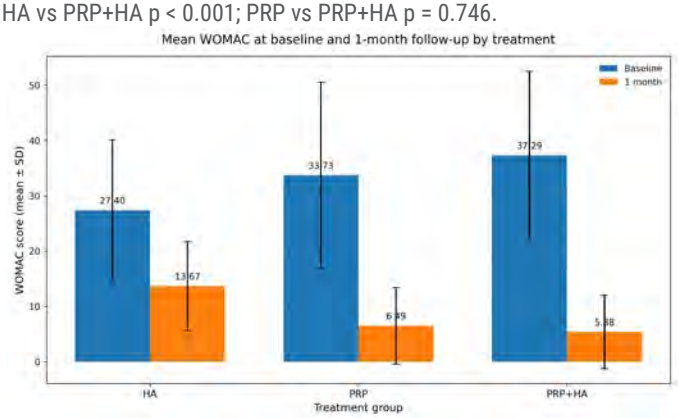
Results At 1 month, VAS pain scores decreased in all groups and were significantly lower with PRP and PRP+HA than with HA (one-way ANOVA $p<0.001$; Tukey $p<0.001$), with no difference between PRP and PRP+HA ($p=0.350$).

Conclusions PRP and PRP+HA provided greater pain reduction than HA alone at one month of follow-up according to VAS scores. These findings are consistent with the analgesic and anti-inflammatory effects attributed to PRP, while HA provides viscosupplementation by improving synovial lubrication and viscoelasticity. Although the combined therapy showed slightly greater clinical improvement, it was not statistically superior to PRP alone. The results support the use of PRP-based therapies when early pain relief is the primary therapeutic objective in symptomatic knee OA.

P102

WOMAC SCALE FUNCTION-FOCUSED: OUTCOMES OF PLATELET-RICH PLASMA, HYALURONIC ACID AND THEIR COMBINED THERAPY IN KNEE OSTEOARTHRITIS

A. A. Cifuentes[1], F. Rodas Flores[2], C. Brincker Nicolas[2], R. J. López Méndez[2], N. J. Gonzalez Licardie de Ancheta[2], B. Lopez Samayoa[3]



[1]Amir Wellness Center, Iniciativa Guatemalteca de Ortobiológicos y Rehabilitación (IGOBIR), Quetzaltenango, Guatemala; [2]Centro Universitario de Occidente at Universidad de San Carlos de Guatemala (USAC), Quetzaltenango, Guatemala; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Knee osteoarthritis (OA) is a common degenerative condition and a major cause of pain and disability. Due to the variable response to conventional treatments, intra-articular therapies such as platelet-rich plasma (PRP) and hyaluronic acid (HA) have gained relevance for their potential to modulate inflammation, improve synovial viscosity, and enhance joint function. Although both treatments have demonstrated clinical benefits, comparative evidence remains limited.

Objective: To compare the effectiveness of PRP, HA, and their combined therapy in the treatment of knee osteoarthritis using the WOMAC scale.

Material and Methods: A cohort study was conducted including 135 patients selected from a population of N=207 with knee OA grades I–III (Kellgren–Lawrence). Participants were allocated into three groups: PRP (n=45), HA (n=45), and PRP+HA (n=45). Treatments followed standardized protocols. WOMAC scores were recorded at baseline and one month after treatment. Data collected from 2022–2025 were analyzed using one-way analysis of variance (ANOVA) and Tukey HSD post-hoc testing.

Results: Mean WOMAC decreased from 27.40 ± 12.72 to 13.67 ± 8.03 (HA), 33.73 ± 16.81 to 6.49 ± 6.89 (PRP), and 37.29 ± 15.24 to 5.38 ± 6.65 (PRP+HA) at 1 month (Figure); ANOVA $p < 0.001$, Tukey: HA vs PRP and HA vs PRP+HA $p < 0.001$; PRP vs PRP+HA $p = 0.746$.

Conclusions:
All treatments produced meaningful improvements in WOMAC scores at

1 month. Mean WOMAC at 1 month was lowest in the PRP+HA group (5.38 ± 6.65), followed by PRP (6.49 ± 6.89), while HA showed the highest residual score (13.67 ± 8.03). HA resulted in significantly higher WOMAC scores than PRP and PRP+HA (both $p < 0.001$), indicating less short-term symptom and function improvement. No significant difference was observed between PRP and PRP+HA ($p = 0.746$), suggesting comparable short-term outcomes with PRP-based regimens. Longer follow-up studies are needed to evaluate durability of benefit and whether combination therapy provides added value over PRP alone over time.

P103

HIGH BURDEN OF OVERWEIGHT AND OBESITY IN KNEE OSTEOARTHRITIS: A RETROSPECTIVE STUDY FROM QUETZALTENANGO, GUATEMALA

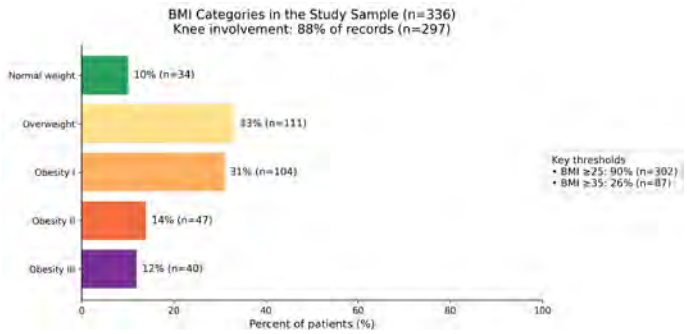
A. A. Cifuentes[1], F. Rodas Flores[2], C. Brincker Nicolas[2], R. J. López Méndez[2], N. J. Gonzalez Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center, Iniciativa Guatemalteca de Ortobiológicos y Rehabilitación (IGOBIR), Quetzaltenango, Guatemala; [2]Centro Universitario de Occidente at Universidad de San Carlos de Guatemala (USAC), Quetzaltenango, Guatemala; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Introduction

Knee osteoarthritis (OA) is a major driver of pain and disability. Excess body weight is a modifiable determinant of knee OA mainly due to mechanical overload. On the other hand systemic low-grade inflammation is consistently linked to worse symptomatic burden. Guatemala-specific clinical data describing BMI profiles among patients with knee OA are limited, constraining locally tailored weight-management strategies aimed at reducing knee pain and improving function.

Objective



To describe the distribution of body mass index (BMI) among patients with knee osteoarthritis treated at a musculoskeletal research center in Quetzaltenango, Guatemala.

Methods

We conducted a retrospective descriptive study of medical records from 2017–2025. From a source population of 762 patients, 336 records were selected using a 95% confidence level for sample size estimation (Z=1.96; p=0.5; q=0.5; E=0.05). For the present report, we focused on patients with knee involvement (n=297). Radiographic OA was classified using Kellgren–Lawrence grades I–III. BMI was categorized as normal weight, overweight, and obesity grades I–III. Descriptive analyses were performed using IBM SPSS.

Results

Among 336 patients with radiographic osteoarthritis (Kellgren–Lawrence I–III), knee involvement was documented in 297 records (88%). The cohort was predominantly female (75%), with a median age of 56 years (range 15–79). BMI distribution revealed a marked excess-weight burden: normal weight 10% (n=34), overweight 33% (n=111), obesity grade I 31% (n=104), obesity grade II 14% (n=47), and obesity grade III 12% (n=40). Overall, 90% of patients had BMI ≥25 kg/m² (n=302) and 26% had BMI ≥35 kg/m² (n=87) (Figure 1).

Conclusion

In this Quetzaltenango clinical cohort with predominantly knee OA, overweight and obesity were highly prevalent, including a substantial proportion with severe obesity. These findings support integrating structured weight-management pathways into knee OA care in Guatemala and highlight the need for prospective local studies linking BMI to standardized knee pain and functional outcomes.

P104

COMPARATIVE RESPONSIVENESS OF THE VISUAL ANALOGUE SCALE AND WOMAC PAIN SUBSCALE IN KNEE OSTEOARTHRITIS

A. A. Cifuentes[1], F. Rodas Flores[2], C. Brincker Nicolas[2], R. J. López Méndez[2], N. J. Gonzalez Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center, Iniciativa Guatemalteca de Ortobiológicos y Rehabilitación (IGOBIR), Quetzaltenango, Guatemala; [2]Centro Universitario de Occidente at Universidad de San Carlos de Guatemala (USAC), Quetzaltenango, Guatemala; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Introduction

Knee OA is a major cause of chronic pain and disability worldwide, making accurate assessment of pain and its response to treatment essential for both clinical practice and research. Patient-reported outcome measures such as the VAS and the pain subscale of the WOMAC are widely used to quantify pain in knee OA. While the VAS provides a simple global measure of pain intensity, the WOMAC pain subscale evaluates pain across specific functional activities, potentially offering greater sensitivity to treatment-related changes. In resource-limited settings such as Guatemala, understanding the comparative responsiveness of these instruments can help optimize follow-up and guide clinical decision-making.

Objective

To evaluate and compare the responsiveness of VAS and WOMAC pain subscale in detecting changes in pain intensity before and after treatment in patients with knee osteoarthritis.

Materials and Methods

A comparative study was conducted on a sample of 135 patients diagnosed with knee OA. Pain intensity was assessed using two instruments: the WOMAC pain subscale (original range 0–20) and the VAS (original range 0–10 points). To ensure metric comparability, VAS scores were mathematically normalized to a 0–20 scale prior to data processing. Statistical analysis was performed using SPSS software, applying descriptive statistics (mean and standard deviation) and the independent samples Student's t-test to determine significant differences

between the mean scores of the instruments.

Results

The comparative analysis revealed statistically significant differences between the instruments (p = 0.019). The WOMAC subscale reported a higher mean score (6.58 ± 3.66) compared to the normalized VAS mean (5.60 ± 3.12). The Student's t-test confirmed this discrepancy, indicating that the WOMAC scale records a higher pain intensity.

Conclusions

The results indicate that the WOMAC pain subscale demonstrates greater sensitivity for detecting pain symptoms compared to the VAS (p = 0.019). While the VAS tends to underestimate pain (mean: 5.60), the multidimensional structure of the WOMAC produced significantly higher scores (mean: 6.58). It is concluded that WOMAC is the most suitable instrument for identifying residual functional pain that the global VAS measurement overlooks, and its use is recommended when a comprehensive assessment of therapeutic efficacy is required.

P105

CONSERVATIVE TREATMENT USING PLATELET-RICH PLASMA ON A PARTIAL TEAR OF THE ANTERIOR CRUCIATE LIGAMENT (ACL): A GUATEMALAN CASE REPORT

A. A. Cifuentes[1], F. Rodas Flores[2], C. Brincker Nicolas[2], R. J. López Méndez[2], N. J. Gonzalez Licardie de Ancheta[2], B. Lopez Samayoa[3]

[1]Amir Wellness Center, Iniciativa Guatemalteca de Ortobiológicos y Rehabilitación (IGOBIR), Quetzaltenango, Guatemala; [2]Centro Universitario de Occidente at Universidad de San Carlos de Guatemala (USAC), Quetzaltenango, Guatemala; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Introduction: Partial anterior cruciate ligament (ACL) injuries represent a diagnostic and therapeutic challenge due to clinical, functional heterogeneity and the risk of progression to complex rupture, especially in young active patients. In adolescents, management requires additional caution to not harm the growth plates and to avoid complications. Conservative management with orthobiologics such as platelet-rich plasma (PRP) has gained interest, but in Guatemala these therapies remain incipient, with limited standardization and specialized centers for management and rehabilitation due to limited health care access.

Objective: To describe the clinical and functional evolution of a partial ACL tear treated conservatively with intra-articular PRP in a young patient.

Case Report: A 15-year-old male patient in Western Guatemala presented with left knee pain and functional limitation of 13 weeks after a soccer injury. Physical examination shows a positive Lachman test, decreased diameter of the left quadriceps femoris, a 10/10 on the Visual Analogue Scale (VAS) and a 26 points on the WOMAC scale. MRI confirmed the presence of a partial ACL injury.

Results: Intra-articular PRP was performed on the left knee (PRP volume per injection 9 mL), with a physiotherapy program focused on strengthening the quadriceps and hamstrings. At one month follow-up, the patient presented partial clinical improvement, with a 5/10 VAS and a 10 WOMAC score; therefore, a second PRP treatment was indicated at eight weeks. At the three month evaluation patient showed pain free (VAS 0/10), significant functional improvement (WOMAC 2 points), and a negative Lachman test.

Conclusion The use of PRP as treatment of partial ACL injuries shows a significant pain reduction, functional and knee stability improvement. This case shows that PRP, combined with a structured rehab program, can be a therapeutic alternative to preserve ligamentous integrity and avoid surgical interventions at an early age.

P106

THE FREQUENCY OF OSTEOSARCOPENIA IN AXIAL SPONDYLOARTHRITIS AND ITS RELATIONSHIP WITH CLINICAL PARAMETERS

I. Aksu[1], A. Genc[1], A. H. Elhan[2], M. Kır[3], S. Ataman[4], A. A. Küçükdeveci[1]

[1]Ankara University, Medical Faculty, Department of Physical Medicine and Rehabilitation, Ankara , Türkiye; [2]Ankara University, Medical Faculty, Department of Biostatistics, Ankara, Türkiye; [3]Ankara University, Medical Faculty, Department of Nuclear Medicine, Ankara, Türkiye; [4]Ankara University, Medical Faculty, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Ankara , Türkiye

Objectives: Osteoporosis is a clinical manifestation of Axial Spondyloarthritis (AxSpA) due to inflammation and immobilization. Similarly, sarcopenia may also develop in AxSpA. Osteosarcopenia may be a significant cause of morbidity and mortality in AxSpA. This study aimed to determine the frequency of osteosarcopenia in patients with AxSpA and investigate its relationship with clinical parameters.

Material and Methods: A total of 97 AxSpA patients (mean age 45, 56% male) and 97 age- and sex-matched healthy controls were included. Osteoporosis was diagnosed using dual-energy X-ray absorptiometry (DXA). Sarcopenia was determined using the European Working Group on Sarcopenia in Older People-2 (EWGSOP2) algorithm, which included measurements of grip strength, muscle mass (measured via DXA and bioelectrical impedance analysis), and physical performance (4-meter walking speed test). The frequency of participants with osteoporosis, as well as probable, definite, and severe sarcopenia were investigated. Osteosarcopenia was defined as the co-existence of osteoporosis and sarcopenia. The relationship of osteoporosis, sarcopenia, and osteosarcopenia with clinical parameters, including age, disease duration, medication use, disease activity, spinal mobility, radiographic involvement, functional status, and physical activity were investigated in AxSpA.

Results: The frequency of osteoporosis was 2.1% and 4.1% in the patient and control groups, respectively. Probable, definite, and severe sarcopenia was identified in 9.3%, 4.1%, and 1% of patients, whereas in controls it was identified in 4.1%, 2.1%, and 1%. Osteosarcopenia was identified only in one patient (1%). No significant differences were found between the groups regarding the frequency of osteoporosis, sarcopenia, or osteosarcopenia ($p>0.05$). Within the AxSpA group, probable sarcopenia was significantly associated with older age ($p=0.001$), limited spinal mobility ($p<0.05$), and worse functional status ($p<0.05$), while definite sarcopenia and osteoporosis were associated only with older age ($p<0.05$). As osteosarcopenia was detected only in one patient, its relation with clinical parameters could not be analyzed.

Conclusion: Frequency of osteoporosis, sarcopenia, and osteosarcopenia in AxSpA was similar to that in healthy controls. Previous studies reported higher frequency rates of osteoporosis and sarcopenia compared to our results. However, in those studies, the average age and disease duration of patients were generally higher, and the rates of anti-TNF drug use were lower compared with the present study.

P107

EFFECT OF A COMBINED PROPRIOCEPTIVE AND MUSCLE STRENGTHENING PROGRAM ON RECURRENT ANKLE SPRAINS

A. Ameur[1], S. Elarem[1], F. Blel[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives:
To evaluate the effectiveness of a structured rehabilitation programme combining proprioceptive training and muscle strengthening in reducing recurrent ankle sprains and improving ankle function.
Material and Methods:
A prospective pilot study including 40 patients with a history of at least one severe ankle sprain occurring more than six months before inclusion. Participants followed a supervised 6-week rehabilitation programme, three sessions per week, including balance exercises, peroneal and tibialis muscle strengthening, and core stability training. Functional outcomes were assessed using the Foot and Ankle Ability Measure (FAAM), pain intensity using a numerical rating scale, ankle range of motion, and recurrence of ankle sprain over a 3-month follow-up.
Results:
After the 6-week rehabilitation programme, the FAAM score significantly improved from 62.4 ± 9.8 to 82.1 ± 8.6 ($p < 0.001$). Pain intensity decreased from 5.6 ± 1.4 to 2.3 ± 1.2 ($p < 0.001$). Ankle dorsiflexion range of motion increased from 12.1 ± 3.5° to 17.8 ± 3.2° ($p = 0.002$). During the 3-month follow-up, the recurrence rate of ankle sprain decreased from 37.5% to 12.5%. Improvements in balance performance were moderately associated with FAAM score changes ($r = 0.48$, $p = 0.01$).
Conclusions:
A combined proprioceptive and strengthening rehabilitation programme appears effective in reducing recurrence and improving functional recovery after ankle sprain. This approach could be recommended as a preventive strategy in patients at risk of chronic ankle instability.
Disclosures:
The authors declare no conflict of interest.

P108

PLANTAR LOAD DISTRIBUTION AND GAIT BIOMECHANICS IN PATIENTS WITH TALOCRURAL OSTEOARTHRITIS

A. Ameur[1], S. Elarem[1], F. Blel[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives:
To analyse plantar load distribution and gait biomechanics in patients with talocrural osteoarthritis and to explore their relationship with pain and functional limitation.
Material and Methods:
A comparative cross-sectional study including 25 patients with symptomatic talocrural osteoarthritis and 25 age-matched healthy controls. Plantar pressure distribution was assessed using a force platform, and gait parameters were analysed with inertial sensors. Outcome measures included peak plantar pressure, centre of pressure displacement, gait speed, step length and pain intensity.
Results:
Patients with talocrural osteoarthritis exhibited significantly higher peak plantar pressure in the forefoot (412 ± 85 kPa) than controls (286 ± 64 kPa, $p < 0.001$). Gait speed was reduced (0.86 ± 0.18 m/s vs 1.21 ± 0.22 m/s, $p < 0.001$), and step length was shorter (0.52 ± 0.09 m vs 0.68 ± 0.11 m, $p = 0.002$). Plantar pressure asymmetry was significantly associated with pain intensity ($r = 0.56$, $p = 0.004$) and functional limitation.
Conclusions:
Talocrural osteoarthritis is associated with significant biomechanical alterations during gait. Objective assessment of plantar load distribution may help guide personalised rehabilitation strategies aimed at reducing pain and improving function.
Disclosures:
The authors declare no conflict of interest.

P109

PREVALENCE AND ASSOCIATED FACTORS OF ANKLE PAIN AND INSTABILITY IN WORKERS WITH PROLONGED STANDING

A. Ameur[1], S. Elarem[1], F. Blel[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives:
To determine the prevalence of ankle pain and instability in workers exposed to prolonged standing and to identify associated risk factors.
Material and Methods:
A cross-sectional study including 150 professionals exposed to prolonged standing. Data were collected using a structured questionnaire assessing ankle pain, history of ankle sprain and occupational exposure. Clinical evaluation included ankle range of motion and stability testing. Associations between ankle disorders and demographic, occupational and clinical factors were analysed.
Results:
Patients with talocrural osteoarthritis exhibited significantly higher peak plantar pressure in the forefoot (412 ± 85 kPa) than controls (286 ± 64 kPa, $p < 0.001$). Gait speed was reduced (0.86 ± 0.18 m/s vs 1.21 ± 0.22 m/s, $p < 0.001$), and step length was shorter (0.52 ± 0.09 m vs 0.68 ± 0.11 m, $p = 0.002$). Plantar pressure asymmetry was significantly correlated with pain intensity ($r = 0.56$, $p = 0.004$) and functional limitation.
Conclusions:
Ankle disorders are common in workers exposed to prolonged standing. Identification of modifiable risk factors supports the implementation of targeted preventive and rehabilitation programmes in occupational settings.
Disclosures:
The authors declare no conflict of interest.

P110

PREVALENCE OF ANKLE MOBILITY LIMITATION IN PATIENTS REFERRED FOR MUSCULOSKELETAL REHABILITATION

A. Ameur[1], F. Blel[1], S. Elarem[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives:
To determine the prevalence of ankle mobility limitation in patients referred for musculoskeletal rehabilitation and to analyse its association with pain and functional impairment.
Material and Methods:
A descriptive cross-sectional study including 200 consecutive patients referred to a physical and rehabilitation medicine department for musculoskeletal disorders. Ankle dorsiflexion range of motion was assessed clinically using a goniometer. Ankle mobility limitation was defined as dorsiflexion <10°. Pain intensity was assessed using a numerical rating scale, and walking ability was evaluated clinically. Associations between ankle mobility limitation and clinical characteristics were analysed.
Results:
Ankle dorsiflexion limitation was observed in 84 patients (42.0%). Patients with limited ankle mobility presented significantly higher pain intensity compared with those without limitation (5.8 ± 1.6 vs 4.1 ± 1.5, p < 0.001). Walking difficulties were more frequent in patients with reduced ankle dorsiflexion (61.9% vs 34.5%, p < 0.001).
Ankle mobility limitation was more prevalent in patients referred for knee disorders (48.6%) and low back pain (44.2%) compared with upper limb conditions (27.3%, p = 0.02). Reduced ankle dorsiflexion was significantly associated with decreased walking speed and the need for walking aids (p < 0.05).
Conclusions:
Ankle mobility limitation is frequent among patients referred for musculoskeletal rehabilitation and is significantly associated with pain and functional impairment. Systematic assessment of ankle mobility should be considered in routine rehabilitation practice to optimise functional outcomes.
Disclosures:
The authors declare no conflict of interest.

P111

ANKLE FUNCTION AND FALL RISK IN OLDER ADULTS WITH MUSCULOSKELETAL DISORDERS

A. Ameur[1], F. Blel[1], S. Elarem[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives: To explore the relationship between ankle mobility, strength, and risk of falls in older adults.

Material and Methods: A cross-sectional study including 120 adults aged ≥65 years referred for musculoskeletal disorders. Ankle range of motion, muscle strength and balance performance were assessed. Fall history during the previous year was recorded.

Results: Among the 120 participants, 46 (38.3%) reported at least one fall during the previous year. Fallers presented significantly reduced ankle dorsiflexion compared with non-fallers (10.2 ± 3.4° vs 15.6 ± 4.1°, p < 0.001). Ankle muscle strength was also lower in fallers (3.1 ± 0.6 vs 3.8 ± 0.7, p = 0.002). Balance performance was significantly impaired in fallers, with longer postural sway duration (p = 0.01). Reduced ankle dorsiflexion was independently associated with increased fall risk (OR = 2.1; 95% CI 1.2–3.8), even after adjustment for age and body mass index.

Conclusions: Ankle function plays a key role in balance and fall prevention. Targeted ankle rehabilitation may represent a modifiable factor to reduce fall risk in older adults.
Disclosures: The authors declare no conflict of interest.

P112

IMPACT OF AN EARLY FUNCTIONAL REHABILITATION PROGRAM AFTER ANKLE FRACTURE

A. Ameur[1], S. Elarem[1], F. Blel[1], I. Haddeda[1], A. Haj Salah[1], M. Sghir[1], W. Kessomtini[1]

[1]CHU Taher Sfar de Mahdia, Mahdia, Tunisia

Objectives: To evaluate the impact of an early functional rehabilitation programme on pain, mobility and functional recovery after ankle fracture.

Material and Methods: A prospective observational study including 45 patients after surgical or conservative treatment of ankle fracture. Patients followed an early rehabilitation programme starting within three weeks, focusing on range of motion, progressive weight-bearing and muscle strengthening. Pain intensity, ankle mobility and functional status were assessed at baseline and at three months.

Results: At three months, patients showed a significant reduction in pain intensity, decreasing from 6.1 ± 1.5 at baseline to 2.8 ± 1.3 (p < 0.001). Ankle dorsiflexion range of motion improved from 9.8±3.1° to 16.5±3.6° (p<0.001), while plantarflexion increased from 28.4 ± 6.2° to 38.9 ± 7.1° (p = 0.003). Functional assessment showed a significant improvement, with 72% of patients able to walk independently without assistive devices at three months compared with 31% at baseline (p < 0.001). Earlier initiation of rehabilitation was associated with better functional recovery and greater ankle mobility (p < 0.05).

Conclusions: Early functional rehabilitation after ankle fracture is associated with improved recovery and reduced pain, supporting its systematic integration into post-fracture management.

Disclosures: The authors declare no conflict of interest.

P113

EVALUTION OF THE EFFECTIVENESS OF ANTI OSTEOPOROTIC TREATMENTS IN REDUCING FRACTURE RISK

A. Sanna[1], A. Angius[1], G. Caggiari[1], C. Doria[1]

[1]SC CLINICA ORTOPEDICA AOU SASSARI, SASSARI, Italy

Background
Osteoporosis is among the most prevalent metabolic bone disorders worldwide and one of the main causes of skeletal fragility and disability in the elderly population. The progressive loss of bone mass and microarchitectural deterioration significantly increase the risk of fragility fractures, leading to considerable clinical and socioeconomic impact. Traditional antiresorptive agents such as bisphosphonates are effective but often limited by poor long-term adherence and tolerability. In recent years, novel biological therapies have expanded the treatment landscape. Denosumab (Prolia®), a fully human monoclonal antibody targeting the RANKL pathway, inhibits osteoclast differentiation and function, thereby reducing bone turnover and improving bone strength.

Objectives
This study aimed to evaluate the clinical and densitometric efficacy of Denosumab in improving lumbar and femoral T-scores, preventing new fragility fractures, and assessing its safety and tolerability in patients with primary osteoporosis. Secondary objectives included evaluating its effect in patients previously unresponsive to bisphosphonates and analyzing adherence over a 36-month follow-up.

Design and Methods
A single-center observational study was conducted on 29 patients (male and female) with primary osteoporosis. Each subject received Denosumab 60 mg subcutaneously every six months. Clinical and densitometric follow-up extended to 36 months, with DEXA scans at the lumbar spine and femoral neck at baseline and at 12, 24, and 36 months. Laboratory parameters (serum calcium, vitamin D, PTH, CTX) and adverse events were recorded. A subgroup of 7 patients had a history of bisphosphonate treatment without significant benefit.

Results
Mean lumbar T-score increased by +0.38 after the first year and by +0.62 in patients treated for at least 36 months. Mean femoral T-score improved by +0.3 to +0.5 in responders. During follow-up, no new fragility fractures were reported despite the high baseline fracture risk. Biochemical analyses showed a consistent reduction in bone resorption markers (CTX), consistent with Denosumab's antiresorptive mechanism. The treatment demonstrated an excellent safety profile, with no clinically significant hypocalcemia or severe adverse events. The 7 patients previously unresponsive to bisphosphonates exhibited meaningful densitometric recovery comparable to or exceeding the study average. Treatment adherence remained high owing to the twice-yearly dosing regimen, which enhanced compliance and reduced discontinuation rates.

Conclusion
Denosumab proved to be a safe, effective, and well-tolerated therapy for primary osteoporosis, producing significant improvements in lumbar and femoral bone density and preventing new fractures in high-risk patients. Its twice-yearly administration supports adherence and long-term management, representing a strategic tool for fracture prevention and healthcare sustainability. In the context of an aging population, Denosumab offers a valuable therapeutic alternative for patients who are intolerant or refractory to bisphosphonates. Large-scale multicenter studies with extended follow-up are warranted to further define its optimal role in the integrated management of osteoporosis.

P114

POST-EXTRACTION MANDIBULAR ANGLE FRACTURE UNMASKING COL1A2 P.ASP1120ASN HIGH-BMD OSTEOGENESIS IMPERFECTA

A. Bashihab[1,2], A. Almalki[1,2], N. Alsudani [1,2].

[1]Department of Endocrinology, Al Hada Armed Forces Hospital, Taif, Saudi Arabia. [2]General Department of Medical Services, Ministry of Defense, Riyadh, Saudi Arabia

Background
Osteogenesis imperfecta (OI) is typically manifest with bone mineral density (BMD) and recurrent fractures. A rare counterphenotype arises when missense variants alter the carboxyterminal propeptide cleavage of type I procollagen (COL1A1/2), impairing extracellular processing , and yielding paradoxically high BMD with brittle bone that radiographically mimic osteopetrosis. Craniofacial involvement heightens dental risk and introduces fixation challenges. We report highBMD OI due to COL1A2 p.Asp1120Asn, highlighting the diagnostic trap of "densebutweak" bone and the practical implications for oral and maxillofacial surgery.
Case presentation
A 32yearold man with lifelong lowtrauma fractures and a residual left forearm deformity. Presented with malocclusion and pain following lower third molar extraction, 3D CT demonstrated a right mandibular angle fracture. Despite mini-plate fixation, hardware failure occurred with recurrent displacement and malunion. A skeletal survey showed generalized osteosclerosis with thickened calvaria, raising an initial differential of osteopetrosis. Biochemistry was unremarkable, including calcium, phosphate, parathyroid hormone, alkaline phosphatase and renal function; vitamin D was sufficient. Dualenergy Xray absorptiometry showed paradoxically high Zscores (hip +1.9; lumbar spine +5.1). Family history was positive in two sons with childhood fractures, consistent with autosomal dominant inheritance. A nextgeneration sequencing panel (Centogene) identified heterozygous COL1A2 c.3358G>A (p.Asp1120Asn), classified as likely pathogenic. The genotype, radiographic pattern and clinical course established the diagnosis of highBMD OI. The maxillofacial team recommended treating future mandibular injuries as pathologic fractures using loadbearing locking reconstruction plates and prolonged intermaxillary guidance. Our endocrine service-initiated family genetic counseling, fracturerisk education, and surveillance planning.
Conclusions
This case underscores that High BMD does not exclude brittle bone disease. Recognizing the COL1A2 Cpropeptidecleavage phenotype prevents misdiagnosis as osteopetrosis, explains fixation failure after dental procedures, and guides tailored management. Adults who fracture despite high Zscores—particularly with craniofacial involvement—should undergo genetic testing, receive preventive dental precautions, and be managed within a multidisciplinary team. Early identification facilitates counseling, improves outcomes, and enables cascade genetic testing for atrisk relatives.

P115

CATCH ME IF YOU CAN: THE ROLE OF MUSCULOSKELETAL ULTRASOUND IN DETECTING SUBCLINICAL ENTHESITIS IN ANKYLOSING SPONDYLITIS

A. Bayoumy[1], A. Ramadan[2], M. Abdelsalam[2], A. Ismail[1]

[1]Faculty of medicine, Al Azhar University., Nasr City, Egypt; [2]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt

Objectives: To Assess the role of Musculoskeletal ultrasound (MSK US) in detection of subclinical enthesitis in a group of Ankylosing Spondylitis patient and crossing it with clinical and laboratory parameters (acute phase reactant and disease activity).

Methods: We conducted a case-control study at a tertiary hospital from June 2024 till June 2025. We included 50 Ankylosing spondylitis (AS) patients and 50 control included in the study. All subjects included were classified according to Modified New York criteria for ankylosing spondylitis. Complete Blood Count (CBC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and BASDAI were calculated to represent disease activity. Ultrasound assessment (fig 1) using Madrid Sonographic Enthesitis Index (MASEI) was applied to measure subclinical enthesitis at 6 pairs of entheses sites. Statistical Analysis was conducted using SPSS.

Results: In the cases group disease duration mean (SD) was 7.14 ± 4.9 years, all participants were asymptomatic, the BASDAI score mean (SD) was 3.4 ± 2.14. Subclinical enthesitis was detected at 34.8% of cases with significant correlation (P<0.001) to ESR (21.98 ± 20.59 mm/h) and CRP (5.87 ± 7.13). The most affected enthesis was Right (Dominant) triceps tendon enthesis (13.8%) and the least affected enthesis was Left Proximal Patellar Ligament enthesis (2.9%).

Conclusions: MSK US is beneficial for detection of subclinical enthesitis and early diagnosis of AS with a strong correlation to laboratory parameters and disease activity. The role of MSK US opens the door for early diagnosis and treatment of AS patients. Bigger longitudinal studies are needed to more accurately detect the validity of MSK US in AS detection.

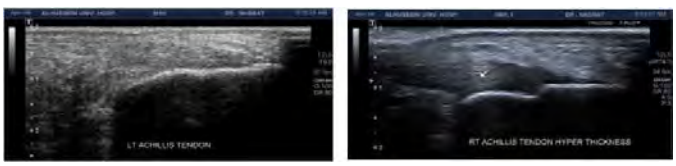


Figure 1: Normal Achilles tendon enthesis. Vs Subclinical enthesitis of the Achilles enthesis.

MUSCULOSKELETAL FRAILTY IN PATIENTS UNDERGOING SPINAL SURGERY DUE TO DEGENERATIVE PATHOLOGIES: PRELIMINARY INSIGHTS FROM THE ORTHOSPINE FITNESS STUDY

S. Gazzotti[1], F. Ponti[1], R. Sassi[1], M. Rossi[2], F. Pugliese[2], M. P. Aparisi Gomez[3,4], G. Fraterrigo[5], E. Schileo[5], F. Taddei[5], G. Barbanti Brodano[2], A. Bazzocchi[1]

[1]Diagnostic and Interventional Radiology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy; [2]Department of Spine Surgery, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy; [3]Department of Radiology, Auckland Hospital (Te Whatu Ora), Auckland, New Zealand; [4]Department of Anatomy and Medical Imaging, Faculty of Medical and Health Sciences, Waipapa Taumata Rau, University of Auckland, Auckland, New Zealand; [5]Bioengineering and Computing Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy

Objective: Musculoskeletal fitness in patients undergoing spinal surgery is still insufficiently addressed. The objective of this work is to outline the prevalence of osteosarcopenia in adults undergoing surgery due to degenerative disease of the thoraco-lumbo-sacral spine.
Material and Methods: The described cohort is part of a large ongoing prospective study aimed at investigating the relationship between frailty and complications of spinal surgery. At baseline, patients are scanned with dual-energy X-ray absorptiometry (DXA) at lumbar spine, hip, and total body. High-resolution peripheral quantitative computed tomography (HR-pQCT) is performed at distal radius and tibia.
Results: This analysis (approximately mid-project) includes 59 operated patients with mean age of 60.7±8.5 years (F:M=2.28:1) and mean T-score at femoral neck of -1.7±1.0 SD. Based on hip T-score, 28 patients (47.5%) were in the osteopenic range and 17 patients (28.8%) in the osteoporotic range. Lumbar spine DXA could only be acquired in 36 subjects: the overall mean T-score was -0.7±2.5 SD with two outliers. After their exclusion, based on T-score, osteopenia could be identified in 12 patients (35.3%) and osteoporosis in 7 patients (20.6%). Total body DXA was performed in 45 individuals with mean fat mass index (FMI) of 9.6±0.3 kg/m2 and 8.4±1.5 kg/m2, lean mass index (LMI) of 15.5±0.2 kg/m2 and 18.5±1.6 kg/m2, and appendicular skeletal mass index (ASMI) of 6.3±1.1 kg/m2 and 8.0±0.9 kg/m2 in females (n=33) and males (n=11/12), respectively. Relying on cut-offs by EWGSOP2, sarcopenia could be detected in 6 women (18.2%; ASMI<5.5 kg/m2) and 2 men (16.7%; ASMI<7 kg/m2). HR-pQCT revealed variable bone phenotypes.
Conclusion: The prevalence of osteopenia/osteoporosis and sarcopenia in patients who require spinal surgery for degenerative pathologies is substantial. Further research is warranted to clarify their influence on post-operative complications.

INTEGRATION OF IMAGES WITH RADIOLOGICAL REPORTS IN THE CONTEXT OF RARE SKELETAL DISEASES CAUSING BONE FRAGILITY: PRELIMINARY RESULTS OF A SURVEY CONDUCTED WITHIN THE BETTER PROJECT

E. Cirami[1], S. Gazzotti[1], D. Paoli[2], M. Mordenti[2], M. P. Aparisi Gomez[3,4], L. Sangiorgi[2], A. Bazzocchi[1]

[1]Diagnostic and Interventional Radiology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy; [2]Department of Rare Skeletal Disorders, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy; [3]Department of Anatomy and Medical Imaging, Faculty of Medical and Health Sciences, Waipapa Taumata Rau, University of Auckland, Auckland, New Zealand; [4]Department of Radiology, Auckland Hospital (Te Whatu Ora), Auckland, New Zealand

Objective: Several skeletal dysplasias are associated with alterations in bone metabolism that determine an increase in fracture risk. Radiology plays a crucial role in their diagnosis and monitoring but images and reports are not necessarily accessible in practice. The purpose of this work is to evaluate the usefulness of integrating selected images into structured radiological reports with the ultimate aim of optimizing the management of rare bone diseases.
Materials and Methods: In the context of the BETTER project, a structured questionnaire was developed and presented anonymously to radiologists, general practitioners, residents, and researchers using the REDCap platform (Italian + English version). The survey comprised multiple-choice and open-ended questions as well as rating scales and was designed to investigate routine access to diagnostic images, diffusion of structured radiological reports, and perceived impact of their availability on patient care.
Results: Preliminary results indicate that the inclusion of selected images could enhance the value of radiological reports at the time of diagnosis and follow-up in patients with increased fracture risk. Respondents reported that the availability of representative images was either highly or quite relevant for their understanding of altered bone structure, facilitating longitudinal monitoring and expediting clinical assessment. However, difficulties in the simultaneous access to images and reports emerged as a relevant operational limitation in daily workflows; in addition, the adoption of structured reporting remained heterogeneous.
Conclusions: Our work suggests that the integration of images with structured reports could represent a valuable tool to improve the clinical management of patients with rare skeletal diseases, enabling easier identification of individuals at increased fracture risk and supporting therapeutic decisions. Further efforts should be devoted to the design of institutional policies aimed at supporting this approach.
Acknowledgements: The BETTER project is funded by the European Union – NextGenerationEU (PNRR-MR1-2023-12377715. Missione 6/componente 2/Investimento: 2.1 "Rafforzamento e potenziamento della ricerca biomedica del SSN").
Disclosures: No conflict of interest.

BONY INCREASED OFFSET REVERSE SHOULDER ARTHROPLASTY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOPOROSIS

E. Naryshkin[1], A. Bimbaeva[1], M. Makarov[1], A. Khramov[1], E. Bialik[1], V. Bialik[1], V. Nesterenko[1], A. Dubinin[1], T. C. Phan[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Background. Reverse shoulder arthroplasty (RSA) in patients with rheumatoid arthritis (RA) is associated with compromised bone quality, chronic inflammation, and an increased risk of complications. The use of bony increased offset reverse shoulder arthroplasty (BIO-RSA) in this population remains controversial, particularly in the presence of osteoporosis.
Purpose. To evaluate graft integration and clinical outcomes of BIO-RSA in patients with rheumatoid arthritis and osteoporosis.
Methods. A retrospective analysis included 50 patients who underwent reverse shoulder arthroplasty with BIO-RSA. Thirty-two patients were diagnosed with rheumatoid arthritis, and eighteen patients had primary osteoarthritis. All patients demonstrated radiological signs of osteoporosis. In the RA group, BIO-RSA with glenoid bone grafting was performed in 19 patients. All patients received preoperative subacromial glucocorticosteroid injections. Radiographic assessment focused on graft integration, while clinical follow-up included postoperative complications.
Results. Complete graft integration was observed in all patients, regardless of underlying pathology or bone quality. No cases of graft resorption or non-union were detected. In the RA group, one postoperative dislocation occurred, while two periprosthetic humeral fractures were recorded. Functional outcomes demonstrated satisfactory shoulder mobility, consistent with previously reported benefits of BIO-RSA.
Conclusion. BIO-RSA can be safely performed in patients with rheumatoid arthritis and osteoporosis, providing reliable graft integration and acceptable complication rates. These findings suggest that osteoporosis and inflammatory joint disease should not be considered absolute contraindications to BIO-RSA.

P119

CLINICAL PREDICTORS OF RITUXIMAB NON-RESPONSE IN RA PATIENTS AFTER BDMARD OR JAKI SWITCHING

A. Bobkova[1], A. Lila[1], E. Zotkin[1], A. Karateev[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russia

Objective:
To identify predictors of rituximab (RTX) ineffectiveness in patients with rheumatoid arthritis (RA) after switching from biologic disease-modifying antirheumatic drugs (bDMARDs) or Janus kinase inhibitors (JAKi).
Methods:
Eighty patients with RA treated with RTX were included. At 6 months, patients were classified as responders (n=39), defined as achieving remission or low disease activity (DAS28-CRP<3.2), and non-responders (n=41), defined as having persistent moderate or high disease activity (DAS28-CRP≥3.2). Mean age was 47.3±13.7 years; 68 patients (85%)

were female. All patients were rheumatoid factor–positive, and 95% were anti–cyclic citrullinated peptide antibody–positive. Baseline ESR and CRP were 34 [14–60] mm/h and 9.8 [2.3–32.0] mg/L, respectively. Median morning stiffness duration was 120 [40–200] minutes; swollen joint count (SJC) was 5 [3–9] and tender joint count (TJC) was 10 [6–15]. Disease activity was assessed using DAS28-ESR (5.6±1.0), DAS28-CRP (5.2±0.9), SDAI (29.8 [24.0–40.5]) and CDAI (29 [21–37]). Pain, fatigue, functional disability, fibromyalgia features, anxiety and depression were evaluated using validated questionnaires (BPI, FSS, HAQ, FiRST and HADS). Social status and concomitant pharmacotherapy were also analyzed.

Results:

Non-responders more frequently had unemployed status (75.6% vs 48.7%, p=0.014) and later RA onset (41.9±11.6 vs 35.5±15.0 years, p=0.036). They exhibited more pronounced joint involvement (TJC 15 [12–19] vs 11 [7–14.5], p<0.001; SJC 9 [5–14] vs 6 [4–9.5], p=0.016) and longer morning stiffness (180 [60–300] vs 90 [30–190] minutes, p=0.025). Baseline disease activity was significantly higher across all indices in non-responders (all p<0.001).

In addition, non-responders demonstrated greater functional disability (HAQ 1.88 [1.63–2.38] vs 1.75 [1.0–2.0], p=0.006), higher levels of depressive symptoms and fatigue (HADS-D 8.0 [5–11] vs 6.0 [4–8.5], p=0.037; FSS 52.0 [42–57] vs 45.0 [33–54.5], p=0.038), as well as higher pain intensity and greater pain-related sleep interference according to BPI (p<0.05). Anxiety symptoms (HADS-A) were more prevalent among non-responders (26.8% vs 7.7%, p=0.038). Immunological profiles did not differ significantly between groups. NSAID use during the 3 months prior to inclusion was more frequent in non-responders (92.7% vs 76.9%, p=0.048).

Conclusion:

RTX ineffectiveness after switching from bDMARDs or JAK inhibitors is associated with high baseline disease activity, pronounced joint involvement, functional disability, high pain burden and psychoemotional disturbances. These clinical and psychosocial factors may serve as potential predictors of RTX treatment ineffectiveness.

P120

GENETIC PREDICTORS OF RITUXIMAB RESPONSE IN RA PATIENTS AFTER SWITCHING FROM BDMARDS OR JAK INHIBITORS

A. Bobkova[1], A. Lila[1], I. Guseva[1], E. Samarkina[1], E. Zotkin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russia

Objective

To assess the association of gene polymorphisms with clinical response to rituximab (RTX) in rheumatoid arthritis (RA) patients after switching from other biologic DMARDs or JAK inhibitors.

Materials and Methods

Seventy-four RA patients with prior inadequate response to bDMARDs/JAK inhibitors were treated with RTX. After 6 months, patients were classified as responders (DAS28-CRP<3.2) or non-responders (DAS28-CRP≥3.2). Mean age was 46.3±12.7 years; 63 patients (85.1%) were female. Baseline ESR and CRP were 32 [14–57] mm/h and 9.7 [2.3–31.8] mg/L, respectively; morning stiffness 120 [40–200] min; tender joint count (TJC) 11 [6–16]; swollen joint count (SJC) 6 [4–9]. Disease activity indices: DAS28-ESR 5.6±1.0, DAS28-CRP 5.2±0.9, SDAI 29.8 [24.0–40.5], CDAI 29 [21–37].

Genotyping included IL-6R (rs2228145), TNFAIP3 (rs10499194, rs6920220), TNFA (rs1800629), CTLA-4 (rs231775), COMT (rs4633), IL-10 (rs1800872), STAT4 (rs7574865), KCNS1 (rs734784), and TNFSF13B/BAFF (rs9514828). Associations with clinical response were analyzed under dominant, recessive, and overdominant genetic models.

Results

C allele carriers of IL-6R (rs2228145) had increased risk of non-response to RTX (AC+CC vs AA: 65.8% vs 34.2%; OR=2.69; 95%CI 1.05–6.90; p=0.037).

Carriers of at least one minor G allele of KCNS1 (rs734784) showed reduced risk of non-response (OR=0.37; 95%CI 0.14–0.99; p=0.046).

No significant associations were observed for TNFSF13B/BAFF (rs9514828) or other polymorphisms.

Conclusion

In RA patients with prior inadequate response to bDMARDs/JAK inhibitors, IL-6R (rs2228145) C allele is associated with increased risk of non-response to RTX, whereas KCNS1 (rs734784) minor G allele is associated with reduced risk. These findings support the potential utility of genetic markers as predictors of treatment response when switching biologic therapy.

P121

BASELINE SERUM CHEMOKINES PREDICT CLINICAL RESPONSE TO RITUXIMAB IN RA PATIENTS AFTER BDMARD/JAKI FAILURE

A. Bobkova[1], A. Lila[1], A. Avdeeva[1], M. Diatroptov[1], E. Samarkina[1], E. Zotkin[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russia

Objective

To identify predictors of rituximab (RTX) inefficacy in rheumatoid arthritis (RA) patients after switching from biologic DMARDs (bDMARDs) and/or Janus kinase inhibitors (JAKi) based on baseline serum chemokine and cytokine levels.

Materials and Methods

Thirty-five RA patients with inadequate response to prior bDMARDs and/or JAKi received RTX. Mean age was 45.7±11.7 years; 28 patients (80%) were female. Seropositivity: RF 97.1%, anti-CCP 94.3%. Baseline disease activity: DAS28-ESR 5.6±1.0, DAS28-CRP 5.2±0.9. Clinical response at 6 months was defined by DAS28-CRP: remission or low disease activity (<3.2) as responders, moderate/high disease activity (≥3.2) as non-responders.

Serum chemokine and cytokine levels were quantified using multiplex xMAP technology (Bio-Plex 40-Plex Panel, Bio-Rad, USA), including CCL7, CXCL13, CCL26, IL-1β, CCL22, CCL23, and additional markers.

Results

Comparison between responders (n=18) and non-responders (n=17) revealed significant baseline differences:

- **CXCL13**: 26.7 [10.3–42.8] vs 45.8 [29.9–104.1] pg/mL; p=0.011
- **CCL7**: 308.3 [114.0–424.4] vs 117.8 [65.2–117.8] pg/mL; p=0.014
- **CCL26**: 55.1 [46.9–68.1] vs 36.6 [31.9–62.6] pg/mL; p=0.032
- **IL-1β**: 1.4 [0.9–1.6] vs 0.8 [0.5–1.2] pg/mL; p=0.007
- **CCL22**: 383.2 [196.6–543.2] vs 226.2 [159.2–370.5] pg/mL; p=0.045
- **CCL23**: 191.8 [95.3–323.6] vs 274.2 [228.7–418.5] pg/mL; p=0.035

Conclusion
Baseline serum chemokine levels are associated with clinical response to RTX in RA patients previously failing bDMARDs/JAKi. **Elevated CXCL13 and CCL23 in non-responders reflect B-cell-mediated (CXCL13) and macrophage-associated chemotactic (CCL23) pathways, potentially contributing to persistent inflammation and reduced RTX efficacy**. Higher baseline CCL7, CCL26, CCL22, and IL-1β levels were associated with favorable response. These findings support the potential of serum chemokines as predictive biomarkers and justify further investigation in the context of personalized RA therapy.

P122
"MENOPAUSE WITHOUT RISK" – OSTEOPOROSIS SCREENING CAMPAIGN IN BULGARIAN COMMUNITY PHARMACIES

A. Boyanova[1], R. Staynova[1], E. Vasileva[2], N. Neycheva[1], H. Manev[3], R. Kareva[4], A. Lilova[5]

[1]Department of Organisation and Economics of Pharmacy, Faculty of Pharmacy, Medical University of Plovdiv, Plovdiv, Bulgaria; [2]Department of Propaedeutics of Internal Diseases, Faculty of Medicine, Medical University of Plovdiv, Plovdiv, Bulgaria; [3]Department of Medical Physics and Biophysics, Faculty of Pharmacy, Medical University of Plovdiv, Plovdiv, Bulgaria; [4]Faculty of Pharmacy, Medical University of Plovdiv, Plovdiv, Bulgaria; [5]Association "Women without Osteoporosis", Sofia, Bulgaria

Objective: The objective of this study was to implement an osteoporosis screening campaign in community pharmacies and to assess osteoporosis-related risk factors among women in the Bulgarian population.
Material and Methods: A pharmacy-based osteoporosis screening campaign was conducted in October 2025, in connection with World Osteoporosis Day, at two community pharmacies in Plovdiv, Bulgaria's second-largest city. Screening included heel ultrasound osteodensitometry and assessment of osteoporosis risk factors using the IOF Osteoporosis Risk Check questionnaire. Following screening, community pharmacists provided individualised education and counselling regarding osteoporosis risk factors and lifestyle recommendations and referred individuals identified as being at high risk for further medical evaluation. Premenopausal, menopausal, and postmenopausal women without a prior diagnosis of osteoporosis were eligible for participation. Descriptive statistics were applied to summarise participant characteristics and risk factors. A General Linear Model Univariate analysis was performed, with T-score treated as a continuous dependent variable.
Results: A total of 287 women participated in the study (mean age 59.7 ± 11.3 years). Of these, 163 (56.8%) women were classified as being at moderate risk (T-score between −1.0 and −2.5), while 86 (30.0%) women were identified as being at high risk (T-score ≤ −2.5). Osteoporosis screening was performed for the first time in 192 participants. Early menopause (before the age of 45 years) emerged as the strongest independent predictor of lower T-scores, showing a statistically significant association ($p < 0.001$). Body mass index category and consumption of three or more servings of dairy products per day were also independently associated with T-score variability, demonstrating smaller but statistically significant effects ($p < 0.05$). All women identified as being at high risk were referred to a general practitioner and an endocrinologist for further assessment.
Conclusion: Community pharmacy–based osteoporosis screening combined with education and counselling was effective in identifying women at increased risk of osteoporosis and was perceived as highly beneficial by participants, highlighting the important role of community pharmacies in osteoporosis prevention and early detection.

P123
IMPACT OF ODONTOMAXILLARY ALTERATIONS ON ORAL HEALTH–RELATED QUALITY OF LIFE IN PATIENTS WITH X-LINKED HYPOPHOSPHATEMIC RICKETS

A. C. Polonsky[1], G. Kluwak[1], M. Morán[1]

[1]Grupo Oroño Rosario, Rosario, Argentina

Introduction
X-linked hypophosphatemia (XLH) is a dominant disorder caused by mutations in the *PHEX* gene that affects bone and dental tissues. It is characterized by skeletal abnormalities and significant oral manifestations, including delayed dental development, malocclusions, structural defects of enamel and dentin, periodontal disease, and premature tooth loss. These alterations predispose patients to spontaneous periapical infections and compromise oral function. Oral health–related quality of life (OHRQoL) reflects the biopsychosocial impact of these conditions and can be assessed using the OHIP-14 questionnaire, which evaluates the effect of oral health problems on daily life across multiple functional and psychosocial domains.
Objective
To describe the findings observed on panoramic dental radiographs (orthopantomography) in a cohort of patients with X-linked hypophosphatemic rickets and to evaluate the relationship between odontological and maxillary alterations and oral health–related quality of life, as measured by the OHIP-14 scale.
Methods
A descriptive, retrospective study was conducted including 14 adult patients with a confirmed diagnosis of XLH. All patients underwent panoramic dental radiography, and oral health–related quality of life was assessed using the OHIP-14 questionnaire
Results:
The study sample consisted of 3 males and 11 females, with ages ranging from 22 to 54 years.

Regarding treatment, four patients were not receiving specific therapy, six were undergoing treatment with burosumab, of whom only two were treated on a continuous basis, while the remaining patients received phosphate salts and calcitriol.

ID: Incomplete dentition, AR: Alveolar resorption, PA: Periapical alteration, RT: retained teeth, TMJ disorder: Temporomandibular joint alteration, DM: Dental malposition, PT: Periodontal thickening, BTA: Bone trabecular alteration, MSO: Maxillary sinus opacification, CT: Conventional Treatment, Y: Yes

Orthopantomographic Findings

- **Incomplete dentition (ID):** 12 patients
- **Alveolar resorption (AR):** 14 patients
- **Periapical alteration (PA):** 8 patients
- **Retention of dental elements (RDE):** 8 patients
- **Dental caries:** 7 patients
- **Cysts:** 7 patients
- **Dental malposition (DM):** 7 patients
- **Periodontal thickening (PT):** 9 patients
- **Bone trabecular alteration (BTA):** 5 patients
- **Maxillary sinus opacification (MSO):** 8 patients
- **Previous dental treatment:** 8 patients

Regarding the OHIP score, a wide dispersion of results was observed, with a mean value of 22.5 and a range from 2 to 34.

Discussion

This study describes odontomaxillary alterations observed on orthopantomography in adults with X-linked hypophosphatemic rickets (XLH) and their association with oral health–related quality of life assessed by the OHIP-14. Structural dental and maxillary abnormalities were highly prevalent and were associated with a negative impact on oral health perception. These alterations, related to defects in mineralized tissues, predispose patients to periodontal disease, periapical infections, and early tooth loss, with consequent functional and psychosocial effects reflected in elevated OHIP-14 scores. The perceived impact varied among patients and appeared to be influenced by factors such as prior dental treatment, access to specialized care, and systemic therapy. Although burosumab represents a major therapeutic advance, its impact on oral health could not be adequately assessed due to limited continuous use in this cohort. Study limitations include the retrospective design, small sample size, and heterogeneity of treatments.

Conclusions

The results underscore the need for a systematic, early, and interdisciplinary dental approach in patients with XLH, as well as comprehensive therapeutic strategies that address not only structural and functional aspects but also patient´s subjective perceptions and quality of life.

P124

COMBINING TERIPARATIDE TO ESTABLISHED DENOSUMAB THERAPY: IMPACT ON BONE MINERAL DENSITY IN A CLINICAL CASE SERIES

A. Carroll[1], F. Brennan[1], A. Mohammed[1], D. Fitzpatrick[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin , Ireland

Objectives.

Combination therapy with denosumab and teriparatide results in greater gains in bone mineral density (BMD) than either therapy alone. However, data on the impact of adding teriparatide to established denosumab therapy is limited with only one small study (n=11) to date. We report on changes in BMD and Collagen Type I C-Telopeptide (CTX) after adding teriparatide to established denosumab therapy in a clinical case series.

Materials and Methods:

We retrospectively identified patients at our osteoporosis clinic who had teriparatide (20 mcg daily) added to established denosumab therapy (at least 12 months). All patients had densitometric (DXA) measured areal BMD at the hip and spine within 6 months before adding TPD and after 18-24 months of combined therapy. We examined for changes in BMD and CTX on treatment.

Results

There were 9 patients, median age 72.0 years (IQR 67.5-78.0). Five had one or more previous vertebral fractures and median duration of denosumab treatment was 7.2 years (IQR 3.8 – 8.3). Median baseline T score at the lumbar spine was -3.9 (IQR -3.4 to 4.1) and -2.2 at total hip (IQR -2.0 to -3.3). Lumbar spine BMD increased in all patients (median +9.2%, IQR 6.6- 19.5%, P=0.004). Six patients were assessed for hip BMD change (two excluded due to technical factors and data missing for one). Change of total hip BMD was inconsistent and insignificant (median 1.42% , p=0.430). CTX increased over the first 6 months (+0.213 ng/ml, p=0.008) and then fell over the next 6 months (−0.194 ng/ml, p=0.008). BMD response was not associated with duration of prior denosumab therapy (p=0.179) or baseline CTX (p=0.258).

Discussion:

Our results show that the addition of teriparatide to established denosumab therapy is associated with a significant increase in lumbar spine (median 9.2%) but not total hip BMD. The findings are similar to the only other comparable study by Kumar et al (n=11) where the mean BMD increase at the spine BMD was 9.8% with no change identified at the hip. The modest increase in CTX at 6 months suggests the possibility of teriparatide induced bone remodelling. More studies are needed to further explore this strategy.

P125

COMPARATIVE STUDY OF TWO FOCAL EXTRACORPOREAL SHOCK WAVE THERAPY PROTOCOLS FOR CHRONIC PLANTAR FASCIITIS: A RANDOMIZED CONTROLLED TRIAL

A. Coloma Garcia[1], J. M. Elia Martinez[1], A. L. Sogues Colom[1], A. Ezzeddine Angulo[1], V. E. Íñigo Huarte[1]

[1]Consorcio Hospital General Universitario de Valencia, Valencia, Spain

Objective(s):to compare the clinical and functional effectiveness of two different focal extracorporeal shock wave therapy (ESWT) protocols for treating chronic plantar fasciitis.
Material and Methods: a randomized controlled trial with 60 patients suffering from chronic plantar fasciitis (>3 months) and an ultrasound-measured fascia thickness exceeding 4 mm.Two groups: the control group (n=30) three sessions of 2,000 pulses every 14 days; study group (n=30) two sessions of 3,000 pulses with the same frequency. Both WITH Intensity of 0.30–0.35 mj/mm2. The primary outcome was the Foot Function Index (FFI) at baseline and 3 months post-treatment. Secondary variables: visual analogue scale (VAS), Euroqol-5d, Roles and Maudsley scale, and ultrasound fascia thickness.
Results: No significant baseline differences were found between groups regarding clinical characteristics or initial FFI (p = 0.1507). Following intervention, both groups showed significant improvements in pain and disability (p < 0.001). Comparison of FFI variation revealed no significant difference between protocols (p = 0.2712). Biomechanical gait analysis showed significant functional activity improvement in the study group (p = 0.0004) which was not statistically significant in the control group (p = 0.215). No significant correlation was observed between ultrasound fascia thickness and clinical variables at baseline or post-treatment. (Figure)
Conclusion(s):Plantar fasciitis represents 11–15% of foot-related consultations. Both ESWT protocols are effective and safe. The two-session protocol is a valid alternative that optimizes healthcare resources and patient treatment time without compromising clinical outcomes.

Otucome Variable	Control Group	Study Group	Post-treatment P-value
Foot Functional Index (FFI) Total	121 ± 42 (Baseline) to 84 ± 64 (Post)	137 ± 44 (Baseline) to 84 ± 63 (Post)	< 0.001
FFI Pain	62 (54, 71) (Baseline) to 41 ± 28 (Post)	71 (56, 81) (Baseline) to 42 ± 29 (Post)	0.008 (Control) / < 0.001 (Study)
FFI Disabilty	47 ± 18 (Baseline) to 25 (5, 62) (Post)	53 ± 24 (Baseline) to 31 (4, 49) (Post)	0.019 (Control) / < 0.001 (Study)
FFI Activity	9 (5, 18) (Baseline) to 5 (1, 19) (Post)	19 (5, 27) (Baseline) to 2 (0, 20) (Post)	0.215 (Control) / 0.0004 (Study)
VAS Pain	6.86 ± 2.05 (Baseline) to 4.31 ± 3.07 (Post)	7.19 ± 1.88 (Baseline) to 4.27 ± 3.05 (Post)	< 0.001

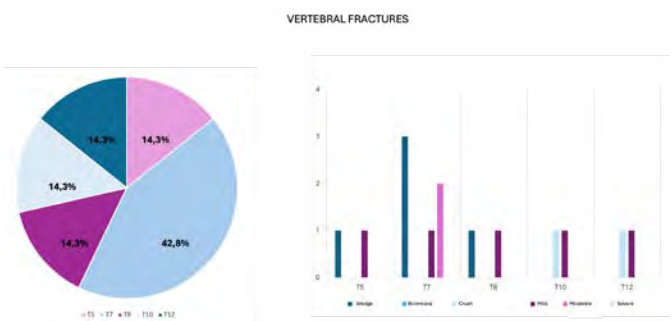
OSCARE: THE OSTEOPOROSIS SELF-CARE QUESTIONNAIRE – DEVELOPMENT AND INITIAL VALIDATION

A. Constantinou[1,2], P. Enthoven[3], M. Wenemark[4,5,6], Y. Lindbäck[3], J. Wibault[3,7], A. Spångeus[1,2]

[1]Division of Diagnostics and Specialist Medicine, Department of Health, Medicine and Caring Sciences, Linköping University, Linköping , Sweden; [2]Osteoporosis Outpatient Clinic, Clinical Department of Activity and Health, Linköping University Hospital, Linköping, Sweden; [3]Unit of Physiotherapy, Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden; [4]Department of Health, Medicine and Caring Sciences, Faculty of Medicine and Health Sciences, Linköping University, Linköping, Sweden; [5]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden; [6]Department of Health Data Analysis, Region Östergötland, Linköping, Sweden; [7]Clinical Department of Activity and Health, Linköping University Hospital, Linköping, Sweden

Objective: To develop and conduct initial validation of the Osteoporosis Self-Care (OSCare) Questionnaire, a new instrument to measure self-care in patients with osteoporosis.
Material and Methods: The OSCare questionnaire was developed in three phases: (1) Item generation through literature review; (2) Content validity assessment by a multidisciplinary expert panel and cognitive interviews (n=8); (3) Construct validity assessment using exploratory factor analysis (EFA; n=302), and reliability using internal consistency (Cronbach's alpha) and test–retest at baseline and two weeks (n=81).The final questionnaire comprised 15 items. Data were derived from a larger cross-sectional osteoporosis survey conducted in Sweden between 2024-2025 that included the OSCare questionnaire. For this survey, a total of 681 patients aged ≥50 years who had received osteoporosis medication within the past year were identified through electronic health records and invited to participate. Of these, 441 responded and were included in the final sample, with 302 respondents completing all OSCare items and thus included in the present analysis.
Results: EFA supported a five-factor structure comprising osteoporosis knowledge (5 items), physical activity (3 items), diet and lifestyle (3 items), treatment adherence (2 items), fall prevention and ergonomics (2 items). Sampling adequacy was good (KMO=0.813), and Bartlett's test of sphericity significant (p<0.001). Internal consistency was good for the osteoporosis knowledge items (α = 0.85) and acceptable for the physical activity items (α = 0.71) and for all items (α = 0.78); other item groups demonstrated low internal consistency, likely due to few items per factor (2-3). Test–retest analysis indicated moderate to very good agreement across most items (κ: 0.43–0.85), with one item indicating fair agreement (κ:0.29).
Conclusion: The OSCare questionnaire demonstrated promising preliminary psychometric properties including content validity and construct validity supported by its factor structure and acceptable overall reliability. However, further refinement is warranted to enhance reliability, and future studies should apply confirmatory factor analysis (CFA) to verify the proposed factor structure.



P127

ASSESSMENT VERTEBRAL FRACTURES AND VASCULAR CALCIFICATIONS IN PERITONEAL DIALYSIS PATIENTS (VERITA-PD STUDY): A PILOT STUDY

A. Cossettini[1], M. Gallieni[1], V. Vizzardi[2], M. Heidemperger[1], G. V. Re Sartò[1], G. Tripepi[3], A. Aghi[4], M. Fusaro[3]

[1]Division of Nephrology and Dialysis, ASST Fatebenefratelli-Sacco, Milan, Italy; [2]Division of Nephrology and Dialysis, ASST Spedali Civili, Brescia, Italy; [3]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy; [4]Indipendent Researcher, Padua, Italy

Background: Vertebral fractures (VF) and vascular calcifications (VC) are frequent complications of Chronic Kidney Disease (CKD) and major contributors to morbidity and mortality. Evidence specifically focusing on peritoneal dialysis (PD) patients remains limited.
Aim: To assess the prevalence of VF, abdominal aortic calcification (AAC), and iliac artery calcifications in PD patients using quantitative vertebral morphometry (QVM) and standardized radiographic scoring.
Methods: In this multicenter, observational pilot study, 15 adult PD patients were evaluated at baseline. Clinical history, PD modality, biochemical parameters, CKD-MBD therapy, and radiographic assessments of VF and VC were collected. VF were analyzed by QVM with SpineAnalizer® and classified according to Genant's method; VC were quantified using the Kauppila score through Calcify2D®.
Results: Among the 15 PD patients (mean age 71.6 ± 18.9 years; 66.7% male; 93.3% APD), six (40%) had ≥1 VF, mainly wedge-shaped and located in the thoracic spine (most frequently T7). Hyperphosphatemia was common (80%), while PTH and calcium levels were mostly within range. AAC was detected in 86.6% of patients (mean Kauppila score 10.9 ± 6.7), and iliac artery calcifications in 66.6%. Comparison with the VIKI study in hemodialysis (HD) patients showed similar demographic and biochemical profiles. VF prevalence was slightly lower in our cohort (40% vs 55.3%, p=0.33), with comparable AAC patterns. Differences in medication use, lipid levels, and alcohol intake likely reflected distinct therapeutic approaches rather than intrinsic biological risk.
Conclusions: PD patients exhibit a high burden of VF and VC, with prevalence comparable to HD cohorts despite different dialysis modalities. To our knowledge, this is the first report describing VF prevalence assessed by QVM exclusively in PD patients and the first to evaluate iliac artery calcifications in this group. These preliminary data support the need for larger studies to refine risk stratification and improve bone and vascular health management in PD.

PSORIATIC ARTHRITIS PRECEDING PSORIASIS: CLINICAL CHARACTERISTICS AND INCIDENCE OF SUBSEQUENT PSORIASIS IN ALGERIAN POPULATION

A. Djebbari[1], A. Gouder[2], S. Bennedjma[3], A. Beguiret[4], S. Oulebsir[5]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Constantine, Algeria; [3]HMRU RHEUMATOLOGY, Algiers, Algeria; [4]Hmusora, Algiers, Algeria; [5]HcA, Algiers, Algeria

Introduction/Objectives: Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the skin and multiple musculoskeletal structures. Although cutaneous psoriasis typically precedes the onset of arthritis, an estimated 7–15% of patients develop PsA before any skin involvement. This subgroup remains insufficiently characterized. The aim of this study was to describe the baseline features of patients in whom PsA precedes psoriasis, to determine the incidence of psoriasis after PsA diagnosis, and to identify factors associated with its subsequent development.

Methods: This retrospective analysis was based on prospectively collected data from the PURE4 cohort dedicated to the early diagnosis of PsA. A total of 69 patients fulfilling the CASPAR classification criteria were included. Among them, 15 patients had a confirmed diagnosis of PsA without known psoriasis at baseline. Comprehensive review of medical records was performed to identify the later onset of psoriasis. Baseline clinical and radiographic features of these patients were compared with those of individuals who presented with psoriasis before or concurrently with arthritis. A multivariable Cox regression model was used to assess factors associated with incident psoriasis.

Results: Of the 69 included patients, 15 had PsA without psoriasis at cohort entry. The cumulative incidence of psoriasis after PsA diagnosis was 8.1 cases per 100 person-years, with a declining trend over time. Compared with patients in whom psoriasis preceded arthritis, those whose arthritis occurred first were significantly younger at diagnosis (35.7 vs. 35.9 years, p ≤ 0.015), had less frequent nail involvement (35.0% vs. 55.7%, p ≤ 0.002), but exhibited more erosive lesions (66.3% vs. 33.24%, p = 0.001) and higher Steinbrocker radiographic scores at presentation (4.1 vs. 2.7, p ≤ 0.001).Tab1 Multivariable analysis showed that treatment with biologic DMARDs (bDMARDs) was associated with a significantly lower risk of subsequent psoriasis (HR 0.32; 95% CI [0.22–0.46], p ≤ 0.001), as was NSAID use (HR 0.44; 95% CI [0.25–0.85], p = 0.02). Conversely, male sex was associated with an increased risk of developing psoriasis (HR 1.27; 95% CI [0.97–2.22], p = 0.001).Tab2

Conclusion: Patients presenting with PsA in the absence of initial psoriasis tend to be younger and display more severe articular damage, possibly reflecting diagnostic delay due to the lack of cutaneous signs. Treatment with bDMARDs and NSAIDs appears to reduce the risk of later psoriasis onset, unlike conventional DMARDs. These findings underscore the importance of early recognition and tailored management of PsA even in the absence of skin involvement.

Table 1.Baseline Characteristics of Patients With PsA Preceding Psoriasis vs. PsA With Prior/Concurrent Psoriasis

Variable	PsA before psoriasis (n=15)	Psoriasis before/ with PsA (n=54)	p-value
Age at diagnosis (years), mean	**35.7**	35.9	≤ 0.015
Nail involvement (%)	**35.0%**	55.7%	≤ 0.002
Erosive lesions (%)	**66.3%**	33.24%	= 0.001
Steinbrocker radiographic score, mean	**4.1**	2.7	≤ 0.001
Sex (male %)	Higher proportion	–	NS
Peripheral arthritis (%)	Similar	–	NS

Table 2. Factors Associated With Incident Psoriasis (Cox Multivariable Model)

Predictor	Hazard Ratio (HR)	95% CI	p-value	Interpretation
bDMARD therapy	**0.32**	0.22–0.46	≤ 0.001	**Significant reduction of psoriasis risk**
NSAID use	**0.44**	0.25–0.85	= 0.02	**Protective effect**
Male sex	**1.27**	0.97–2.22	= 0.001	**Higher risk of psoriasis onset**
cDMARD therapy	No significant association	–	–	–

P129

STRUCTURAL SPINAL PROGRESSION IN EARLY AXIAL SPONDYLOARTHRITIS: PROSPECTIVE ANALYSIS OF 25 CASES FROM ALGERIA DURING 24 MONTHS

A. Djebbari[1], S. Bennedjma[2], A. Gouder[3], A. Beguiret[4], S. Oulebsir[5]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Algiers, Algeria; [3]HMRU RHEUMATOLOGY, Constantine, Algeria; [4]Hmusora, Algiers, Algeria; [5]HcA, Algiers, Algeria

Introduction/Objectives The aim of this prospective study was to assess the rate of structural spinal progression over two years and to identify predictors of radiographic progression in patients with early axial spondyloarthritis (axSpA).

Materials and Methods A total of 25 patients with early axSpA were included in this single-center study based on the availability of baseline and 24-month follow-up spinal radiographs. Cervical and thoracolumbar spine radiographs were evaluated by two trained, blinded independent readers using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Radiographic progression was defined as a mean increase of at least 2 mSASSS points over the follow-up period.

Results In this small cohort of 25 patients, 20% showed radiographic spinal progression after two years, a proportion consistent with findings from larger longitudinal cohorts. Independent predictors of radiographic progression were:Baseline presence of syndesmophytes (OR ≈ 6.29, p < 0.001)Elevated systemic inflammation, including erythrocyte sedimentation rate (ESR) (OR ≈ 4.04, p = 0.001) and mean CRP level over two years (OR ≈ 3.81, p = 0.001). Active smoking (OR ≈ 2.75, p = 0.012). These associations remained significant after multivariate logistic regression analysis. No significant association was found with HLA-B27 status, sex, age, disease duration, BASDAI activity score, BASFI functional index, peripheral or entheseal involvement, psoriasis, or initial treatment (NSAIDs or DMARDs).

Conclusion In this small cohort of early axSpA, the strongest predictors of two-year radiographic spinal progression were the presence of structural damage at baseline (syndesmophytes), high systemic inflammatory burden, and smoking. These observations are consistent with previous findings, particularly from the German GESPIC cohort, which identified baseline syndesmophytes, elevated ESR/CRP, and smoking as key determinants of mSASSS progression (≥2 points over 2 years).

Table 1. Baseline Characteristics and Radiographic Progression at 24 Months

Variable	Value
Number of patients	25
Follow-up duration	24 months
Radiographic spinal progression (≥2 mSASSS points)	**20% of patients**
Mean age	~ Similar across progressors and non-progressors
Sex distribution	No significant difference
HLA-B27 positivity	Not associated with progression
BASDAI score at baseline	Not predictive
BASFI score at baseline	Not predictive
Presence of peripheral disease	No association
Presence of enthesitis	No association
Psoriasis	Not associated with progression
Initial NSAID or DMARD use	No significant association

Table 2. Predictors of Radiographic Spinal Progression

Predictor	Odds Ratio (OR)	p-value	Interpretation
Baseline syndesmophytes	≈ 6.29	< 0.001	Strong independent predictor of progression
Elevated ESR	≈ 4.04	0.001	Higher systemic inflammation increases risk
Mean CRP over 2 years	≈ 3.81	0.001	Persistent inflammation predicts progression
Active smoking	≈ 2.75	0.012	Smoking significantly associated with progression
HLA-B27 status	NS	NS	No predictive value
Sex	NS	NS	No association
Age	NS	NS	No association
Disease duration	NS	NS	Not predictive
Peripheral / entheseal manifestations	NS	NS	Not associated
Initial NSAID or DMARD therapy	NS	NS	No protective effect

P130

DIAGNOSTIC DELAY AND CLINICAL BURDEN IN WOMEN WITH AXIAL SPONDYLOARTHRITIS: FINDINGS FROM AN ANALYSIS OF 45 ALGERIAN PATIENTS

A. Djebbari[1], S. Bennedjma[2], A. Gouder[3], S. Oulebsir[4], A. Beguiret[5]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Algiers, Algeria; [3]HMRU RHEUMATOLOGY, Constantine, Algeria; [4]HcA, Algiers, Algeria; [5]Hmusora, Algiers, Algeria

Introduction The aim of this study was to explore sex-related disparities in a cohort of patients diagnosed with axial spondyloarthritis (axSpA).

Materials and Methods This cross-sectional study was conducted in Algeria and included 71 patients with axSpA (45 men and 26 women) enrolled between 2020 and 2022. The following domains were assessed:Sociodemographic characteristics: age, educational level, employment status, marital status, smoking, alcohol intake, and physical activity.Clinical profile: age at symptom onset, diagnostic delay, HLA-B27 positivity, family history, and extra-articular manifestations (uveitis, psoriasis, inflammatory bowel disease).Disease activity and functional impact: BASDAI score, spinal stiffness, and functional limitation. Therapeutic management: use of NSAIDs, conventional synthetic DMARDs (csDMARDs), and biologic DMARDs (bDMARDs).

Univariate and multivariate logistic regression analyses were performed to evaluate the association between sex and each of these parameters, adjusting for relevant confounders.

Results Among the 71 included patients, 45 were men and 26 were women. The main findings were:Diagnostic delay: Women experienced a significantly longer delay before receiving a diagnosis, with an estimated mean difference of +2.4 years compared with men. HLA-B27 positivity: Women had a lower frequency of HLA-B27 positivity than their male counterparts. Treatment patterns**:** Women showed a higher use of NSAIDs, csDMARDs, and bDMARDs compared with men.

Conclusions This study highlights important sex-specific disparities in the diagnosis and management of axSpA. Women experienced longer diagnostic delays, were less frequently HLA-B27 positive, and were more likely to receive pharmacologic treatments. Recognizing these differences may help clinicians refine diagnostic strategies, reduce disease burden, and promote earlier and more individualized interventions for axSpA patients in Algeria.

Table 1. Baseline Characteristics by Sex in 71 axSpA Patients

Characteristics	Men (n = 45)	Women (n = 26)	Sex Difference
Diagnostic delay (years)	Shorter	**+2.4 years longer on average**	Women significantly more delayed
HLA-B27 positivity	Higher frequency	**Lower frequency**	Women less likely to be HLA-B27+
Age at symptom onset	Similar	Similar	No significant difference
Extra-articular features (uveitis, psoriasis, IBD)	Comparable	Comparable	No significant difference
BASDAI activity score	Comparable	Comparable	No significant difference
Functional impairment (spinal stiffness, BASFI)	Similar ranges	Similar ranges	No significant difference
Lifestyle factors (smoking, alcohol, physical activity)	More frequent smoking	Less frequent smoking	Expected sex-linked pattern

Table 2. Differences in Therapeutic Management Between Men and Women

Treatment	Men (n = 45)	Women (n = 26)	Interpretation
NSAID use	Lower	**Higher**	Women more frequently treated with NSAIDs
csDMARD use	Lower	**Higher**	Women more often prescribed csDMARDs
bDMARD use	Lower	**Higher**	Women more frequently escalated to biologics
Corticosteroids	Similar	Similar	No clinically meaningful difference
Treatment intensity overall	Lower	**Higher therapeutic burden**	Reflects higher clinical burden in women

P131

PREDICTIVE FACTORS OF ACUTE ANTERIOR UVEITIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: FINDINGS FROM A 36-MONTH COHORT STUDY

A. Djebbari[1], A. Beguiret[2], S. Bennedjma[3], S. Oulebsir[4], A. Gouder[5]

[1]HMRU rheumatology, Constantine, Algeria; [2]Hmusora, Algiers, Algeria; [3]HMRU RHEUMATOLOGY, Algiers, Algeria; [4]HcA, Algiers, Algeria; [5]HMRU RHEUMATOLOGY, Constantine, Algeria

Introduction/Objectives Acute anterior uveitis (AAU) is the most common extra-articular manifestation observed in axial spondyloarthritis (axSpA). The primary objective of this study was to identify factors associated with the occurrence of AAU episodes in patients with axSpA over a 36-month longitudinal follow-up.

Methods We analyzed an observational cohort of axSpA patients followed for 36 months. Demographic variables, clinical characteristics, markers of disease activity, and therapeutic regimens were compared between patients with and without a history of AAU. The occurrence and determinants of AAU episodes during follow-up were examined using a generalized estimating equations (GEE) model adapted for longitudinal data analysis.

Results Among the 86 enrolled patients, 26 (30.2%) experienced at least one AAU episode during follow-up. Of these, 20 patients (77%) had a documented history of AAU prior to inclusion, and 15 patients (57.6% with prior AAU) presented one or more additional episodes during the 36-month period.

At baseline, patients with a history of AAU were:Significantly younger ($p = 0.0001$),More likely to have peripheral arthritis ($p < 0.003$), Exhibited

higher C-reactive protein (CRP) levels (p = 0.002),More frequently treated with sulfasalazine (SSZ) or TNF-inhibitors (both p < 0.001).

In the longitudinal analysis, a prior history of AAU was the only independent predictor of AAU recurrence.

Conclusions A previous episode of AAU is an independent risk factor for recurrence in patients with axSpA. Although SSZ and TNF-inhibitors were more frequently used in patients with prior AAU, their protective effect against recurrence was not supported by this study. These findings highlight the need for careful monitoring of high-risk patients and further research into effective strategies for AAU prevention.

Table 1. General Characteristics of the Study Population (N = 71)

Variables	Findings
Sample size	71 patients
Mean age	(to add if needed)
Sex distribution	45 men (63.3%) – 26 women (36.7%)
Diagnostic delay	**2.4 years longer in women**
HLA-B27 positivity	More frequent in men
Clinical form	Predominantly axial
Extra-articular manifestations	Uveitis / Psoriasis / IBD: similar frequencies between sexes
Disease activity (BASDAI)	No significant sex difference
Functional impairment (BASFI)	Comparable between men and women
Lifestyle factors	Smoking more common in men

Table 2. Treatment Received According to Se

Treatment	Men	Women	Interpretation
NSAIDs	–	**Higher use**	Women more frequently treated with NSAIDs
csDMARDs	–	**More frequent prescription**	Higher use in women
Biologic therapies (anti-TNF, others)	–	**More common**	More escalation to biologics in women
Corticosteroids	Similar	Similar	No significant difference
Overall therapeutic intensity	Lower	**Higher**	Higher therapeutic burden in women

DIFFICULT-TO-TREAT AXIAL SPONDYLOARTHRITIS PATIENTS: COSS-SECTIONAL ANALYSIS OF 27 ALGERIAN PATIENTS

A. Djebbari[1], S. Bennedjma[2], A. Beguiret[3]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Algiers, Algeria; [3]Hmusora, Algiers, Algeria

Objectives: This study sought to propose operational criteria for defining *difficult-to-treat* (D2T) axial spondyloarthritis (axSpA) and to determine both the prevalence and clinical profile of D2T patients within our cohort.

Patients and Methods: A cross-sectional analysis was carried out in a cohort of 27 individuals diagnosed with axSpA. All patients were managed in accordance with the European Alliance of Associations for Rheumatology (EULAR) recommendations for axSpA. Eligibility for D2T status required either failure of ≥2 biological or targeted synthetic DMARDs with different mechanisms of action, or failure of ≥3 biological/targeted synthetic DMARDs overall. Potential determinants associated with D2T disease were evaluated, and the clinical and demographic features of patients meeting D2T criteria were compared with those who did not.

Results: Among the 27 included patients, the proportion meeting the proposed D2T definition was substantial. Demographic variables—including sex, age, age at diagnosis, professional activity, and educational level—did not significantly differ between D2T and non-D2T individuals. Enthesitis was markedly more prevalent among D2T patients (p < 0.001). Moreover, measures of disease activity and inflammatory markers were consistently higher in the D2T group, who also demonstrated poorer quality-of-life scores.

Conclusion: A notable subset of axSpA patients fulfilled the D2T criteria despite the availability of multiple therapeutic options. These findings highlight the need for refined management strategies targeting persistent disease activity and associated comorbidities such as fibromyalgia.

Table 1. Characteristics and Outcomes of D2T vs Non-D2T AxSpA Patients (n = 27)

Variable	D2T Patients (n = 12)	Non-D2T Patients (n = 15)	p-value / Interpretation
Sex (male/female)	58%/42%	64%/32%	No significant difference
Age, mean ± SD	51.4 ± 14.3	49.23±14.2	NS
Age at diagnosis, mean ± SD	26.12±16.54	30.2±13.5	NS
Education level	3	3	NS
Enthesitis	75%	38%	p < 0.001
Disease activity (BASDAI, ASDAS)	Higher	Lower	NS
CRP	12.3±10.2	9.45±4.1	NS
Quality of life	Worse	Better	NS

P133

FACTORS ASSOCIATED WITH A SHORTER TRANSITION FROM PSORIASIS TO PSORIATIC ARTHRITIS: RETROSPECTIVE DATA FROM ALGERIA

A. Djebbari[1], A. Gouder[2], S. Bennedjma[3]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Constantine, Algeria; [3]HMRU RHEUMATOLOGY, Algiers, Algeria

Introduction/Objectives: Psoriatic arthritis (PsA) is a chronic inflammatory disease that develops in patients with psoriasis (PsO) after a mean latency of 7 to 10 years. Currently, there are no data specifying the time interval from PsO onset to PsA development, which may contribute to diagnostic delays and poorer outcomes. This study aimed to identify demographic and clinical factors associated with a shorter interval between psoriasis and the onset of PsA.

Materials and Methods: We conducted a retrospective analysis of Algerian patients diagnosed with PsA between 2015 and 2023. All patients fulfilled CASPAR criteria. The transition time from psoriasis to PsA was calculated in years. Patients were categorized into three groups: short transition (ST): <4 years, medium transition (MT): 4–7 years, and long transition (LT): ≥7 years. We compared the groups according to sex, age at psoriasis diagnosis, family history of psoriasis, BMI, treatments, hypertension, diabetes, dyslipidemia, nail involvement, DLQI, ESR/CRP levels, alcohol consumption, and smoking. Factors associated with a shorter transition interval were analyzed using logistic regression models.

Results: A total of 63 patients were included, with a median age of 56 years; 56.6% were women. The median age at psoriasis diagnosis was 33.4 years. No statistically significant differences were observed in demographic characteristics among the three transition groups. However, older age at psoriasis diagnosis (OR = 2.42, 95% CI: 1.12–4.98) and higher BMI (OR = 1.86, 95% CI: 1.51–3.15) were independently associated with a shorter interval between psoriasis and PsA. There were no significant differences in clinical, radiological, therapeutic outcomes, or comorbidities across the groups. Notably, elevated CRP levels (OR = 1.86, 95% CI: 1.16–4.02) were also significantly associated with a shorter transition time.

Conclusion: Higher BMI, older age at psoriasis onset, and elevated inflammatory markers are associated with a shorter interval between plaque psoriasis and PsA. Patients with these risk factors may benefit from early screening for psoriatic arthritis, potentially enabling earlier diagnosis and intervention.

P134

BASELINE PREDICTORS OF RADIOGRAPHIC PROGRESSION IN EARLY PSORIATIC ARTHRITIS: FINDINGS FROM A PURE 4 ALGERIAN COHORT

A. Djebbari[1], A. Gouder[2], N. Taleb[3], K. Zouchoune Ka[3], R. Ayed[3]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Constantine, Algeria; [3]HMRU RHEUMATOLOGY, Algiers, Algeria

Objective: Persistent joint inflammation in psoriatic arthritis (PsA) is strongly linked to structural radiographic damage. Despite improvements in diagnostic strategies and targeted therapies, radiographic progression continues to be observed. This study aimed to identify baseline clinical characteristics associated with radiographic progression in PsA.

Methods: This analysis drew on data from a rPURE 4 Algerian cohort of 53 patients with newly diagnosed PsA. Radiographic progression of hands and feet was evaluated using the modified Total Sharp/van der Heijde Score (mTSS) adapted for PsA. Baseline predictors of radiographic deterioration were examined using univariable and multivariable mixed-effects negative binomial regression models.

Results: The study included 53 early PsA patients with radiographs obtained at baseline and during follow-up. At diagnosis, patients who later developed radiographic progression showed markedly higher mTSS values compared with non-progressors. Individuals in the progressive group were generally older and presented more often with swollen joints at baseline. In the multivariable model, older age, male sex, and higher baseline mTSS were independently associated with an increased risk of radiographic progression over time. Within the subgroup of patients who progressed structurally, baseline disease activity score and swollen joint count were additional predictors of subsequent radiographic worsening.

Conclusion: In this cohort of patients with early Algerian PsA, radiographic progression remained limited under contemporary treatment strategies. Baseline age and structural damage were the main predictors of later progression, whereas female sex appeared to exert a protective effect. Among patients who progressed, higher disease activity and swollen joint burden at diagnosis were associated with greater radiographic deterioration during follow-up.

Table 1. Baseline Characteristics of Progressive vs Non-Progressive PsA Patients (n = 53)

Variable	Progressive group (n = 12)	Non-progressive group (n = 41)	p-value
Age, mean ± SD (years)	**58.7 ± 11.3**	**48.1 ± 12.9**	**0.01**
Female sex, n (%)	**3 (25%)**	**19 (46%)**	**0.04**
Baseline mTSS, median (IQR)	**15 (4–32)**	**1 (0–2)**	**< 0.001**
Swollen joint count ≥1, n (%)	**11 (92%)**	**28 (68%)**	**0.03**
Tender joint count ≥1, n (%)	**9 (75%)**	**23 (56%)**	**0.12**
Elevated CRP (>5 mg/L), n (%)	**8 (67%)**	**20 (49%)**	**0.18**

DISEASE ACTIVITY IN PSORIATIC ARTHRITIS IS ASSOCIATED WITH ATHEROGENIC DYSLIPIDEMIA: A STUDY OF 53 PATIENTS

A. Djebbari[1], S. Bennedjma[2], A. Beguiret[3], S. Oulebsir[4]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Algiers, Algeria; [3]Hmusora, Algiers, Algeria; [4]HcA, Algiers, Algeria

Background/Purpose: Psoriatic arthritis (PsA) is strongly linked to obesity and increased cardiovascular risk. Lipid abnormalities are a major contributor to this risk; however, the association between PsA disease activity and lipid profiles remains insufficiently explored. This study evaluated the relationship between PsA activity and lipid parameters in a real-world cohort.

Methods: A cross-sectional analysis was conducted in a cohort of 53 PsA patients with complete assessments of lipid levels and disease activity. Moderate-to-high disease activity was defined as CDAI >10 and/or the presence of enthesitis or dactylitis. Abnormal lipid values were

categorized as follows: total cholesterol (TC) >200 mg/dL, HDL <40 mg/dL (men) or <50 mg/dL (women), LDL >100 mg/dL, triglycerides (TG) >150 mg/dL, and atherogenic ratio (TC/HDL) >5. Multivariable models were adjusted for gender, PsA duration, BMI, smoking status, disease-modifying therapy, diabetes, and use of lipid-lowering agents.

Results: Of the 53 included patients, 21 (39.6%) had moderate-to-high disease activity. Compared with those in low disease activity, this group showed a higher proportion of women (60% vs. 48%), more smokers (14% vs. 8%), and a shorter disease duration (mean 8.1 vs. 10.5 years). Diabetes was slightly more common in the moderate-to-high activity group (17% vs. 13%). Patients with higher disease activity were more frequently treated with corticosteroids (15% vs. 6%) and csDMARDs (67% vs. 52%), while fewer received TNF inhibitors (53% vs. 64%). BMI was higher in the moderate-to-high activity group (32.1 vs. 30.4 kg/m²).

Moderate-to-high disease activity was significantly associated with elevated TC >200 mg/dL (OR = 1.7; 95% CI: 1.1–2.4, p = 0.01) and elevated TG >150 mg/dL (OR = 1.8; 95% CI: 1.3–2.6, p = 0.008). Enthesitis or dactylitis was also linked to TC elevation (OR = 1.6; 95% CI: 1.1–2.5, p = 0.02). No significant associations were found between disease activity and LDL or HDL abnormalities. Triglyceride levels were slightly higher than previously reported (mean increase ≈12–15% in high activity patients).

In the longitudinal subset (n = 18), higher PsA disease activity correlated with increased TG levels (β = 4.10, p = 0.02) and decreased HDL (β = −0.68, p = 0.01), independent of time between measurements.

Conclusion: Higher PsA disease activity is associated with a more atherogenic lipid profile, particularly elevated triglycerides and total cholesterol. Increasing inflammation also appears to worsen TG and HDL levels over time. This dyslipidemic pattern mirrors that observed in obesity, suggesting shared inflammatory–metabolic mechanisms linking PsA, obesity, and cardiovascular disease risk.

TABLE 1. Baseline Characteristics According to Disease Activity (N = 53)

Variable	Low Disease Activity (n = 32)	Moderate–High Disease Activity (n = 21)
Women, n (%)	15 (48%)	13 (60%)
Smokers, n (%)	3 (8%)	3 (14%)
Disease duration, years (mean ± SD)	10.5 ± –	8.1 ± –
Diabetes, n (%)	4 (13%)	4 (17%)
BMI, kg/m² (mean ± SD)	30.4 ± –	32.1 ± –
Corticosteroid use, n (%)	2 (6%)	3 (15%)
csDMARD use, n (%)	17 (52%)	14 (67%)
TNF inhibitor use, n (%)	20 (64%)	11 (53%)

TABLE 2. Lipid Abnormalities and Their Association With Disease Activity

Outcome / Predictor	OR 95% CI	95% CI	p-value
TC >200 mg/dL	OR = 1.7	1.1–2.4	0.01
TG >150 mg/dL	OR = 1.8	1.3–2.6	0.008
Enthesitis/dactylitis → TC elevation	OR = 1.6	1.1–2.5	0.02

STRUCTURAL SPINE LESIONS IN ALGERIAN AXIALE SPONDYLARTHRITIS: NO ADDITIONAL BURDEN FROM CO-EXISTING PSORIASIS

A. Djebbari[1], A. Gouder[2]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Constantine, Algeria

Background/Purpose: Patients with ankylosing spondylitis and concomitant psoriasis (AS-Pso) are traditionally described as older, more often smokers, and more frequently overweight, with a lower prevalence of HLA-B27 and a balanced sex ratio compared with patients without psoriasis (AS-NPso). However, data regarding spinal structural damage in this subgroup remain limited. This study aimed to compare radiographic spinal involvement in AS according to the presence or absence of psoriasis.

Methods: This retrospective monocentric study included 63 patients with AS followed between 2008 and 2021. All fulfilled the modified New York criteria, presenting definite radiographic sacroiliitis. Demographic, clinical, and radiographic data were collected at the same visit. Spinal radiographs were evaluated by an experienced reader blinded to psoriasis status using the RASSS (0–84) and mSASSS (0–72), with excellent intra-reader reliability (>0.80).

Results: Among the 63 included patients, 15 (23.8%) had psoriasis. The median age was 52 years [46–61], with a predominance of males (68%) and smokers (63%). HLA-B27 was positive in 75%, and the median disease duration was 13 years [6–24]. Use of csDMARDs was slightly higher in the AS-Pso group (28% vs. 20%). Baseline characteristics were broadly comparable between AS-Pso and AS-NPso, except for smoking, which remained more prevalent in AS-NPso.

Radiographic structural damage was observed in 40 patients (63.4%) according to the RASSS and 35 patients (55.5%) according to the mSASSS.Mean RASSS scores were 12.6 (±18.7) in AS-NPso and 11.1 (±15.8) in AS-Pso (p=0.58).Mean mSASSS scores were 10.2 (±15.4) and 9.4 (±14.1), respectively (p=0.62).

No significant differences between groups were identified for RASSS or mSASSS subscores. Analysis by disco-vertebral unit (DVU) showed no preferential site of structural lesions in patients with or without psoriasis.

Linear regression revealed associations between radiographic severity and older age (β=0.21; p=0.01), longer disease duration (β=0.27; p=0.003), male sex (β=0.19; p=0.02), and CRP >5 mg/L (β=0.17; p=0.04) for the RASSS. For the mSASSS, similar associations were detected with age, disease duration, and male sex. In the AS-Pso subgroup, male sex remained the only independent factor associated with both RASSS (β=0.46; p=0.01) and mSASSS (β=0.38; p=0.03).

Conclusion: In this cohort of AS patients, the presence of psoriasis did not influence the degree or pattern of spinal radiographic structural damage as assessed by RASSS or mSASSS. Male sex emerged as the principal determinant of structural involvement among AS-Pso patients. Traditional factors associated with spinal damage—age, disease duration, male sex, and elevated CRP—were confirmed in this population.

Table 1. Baseline Characteristics of AS Patients With and Without Psoriasis (N = 63)

Characteristic	AS-NPso (n = 48)	AS-Pso (n = 15)	p-value
Age, years, median [IQR]	52 [46–60]	53 [47–62]	0.71
Male sex, n (%)	33 (68.7%)	10 (66.7%)	0.88
Smokers, n (%)	32 (66.7%)	8 (53.3%)	0.31
BMI, kg/m² (mean ± SD)	27.8 ± 4.1	28.2 ± 4.3	0.74
HLA-B27 positive, n (%)	36 (75%)	11 (73.3%)	0.89
Disease duration, years, median [IQR]	13 [6–24]	14 [7–25]	0.65
csDMARD use, n (%)	10 (20.8%)	4 (26.7%)	0.61
CRP >5 mg/L, n (%)	19 (39.6%)	6 (40.0%)	0.97

Table 2. Radiographic Structural Damage According to Psoriasis Status

Radiographic Measure	AS-NPso (n = 48)	AS-Pso (n = 15)	p-value
Structural damage (RASSS ≥1), n (%)	31 (64.6%)	9 (60.0%)	0.72
Structural damage (mSASSS ≥1), n (%)	27 (56.2%)	8 (53.3%)	0.82
RASSS score (mean ± SD)	12.6 ± 18.7	11.1 ± 15.8	0.58
mSASSS score (mean ± SD)	10.2 ± 15.4	9.4 ± 14.1	0.62
Preferential DVU involvement	None	None	–
Predictors of higher RASSS: age, disease duration, male sex, CRP >5 mg/L	✓	–	–
Predictors of higher mSASSS: age, disease duration, male sex	✓	–	–
Predictors in AS-Pso subgroup	–	Male sex (p<0.05)	–

P137

PREVALENCE OF EARLY MSK ABNORMALITIES AND CASPAR-DEFINED PSA IN A 141-PATIENT PSORIASIS ALGERIAN COHORT

A. Djebbari[1], A. Beguiret[2], S. Bennedjma[3]

[1]HMRU rheumatology, Constantine, Algeria; [2]Hmusora, Algiers, Algeria; [3]HMRU RHEUMATOLOGY, Algiers, Algeria

Background: Psoriasis (Pso) cohorts offer an ideal setting to identify early clinical features associated with future psoriatic arthritis (PsA), as cutaneous disease typically precedes joint involvement by nearly three years. Understanding baseline characteristics may help detect patients at higher risk of transition.

Objectives: To describe baseline musculoskeletal (MSK) and clinical features in an early psoriasis cohort and classify patients into predefined clinical categories relevant for long-term follow-up.

Methods: Patients were recruited from the PURE 4 Algerian cohort. Inclusion criteria were adults aged ≥18 years with dermatologist-confirmed Pso of <10 years' duration. Exclusion criteria included severe active comorbid illness, prior inflammatory arthritis, or ongoing systemic immunosuppressive therapy for Pso.

At baseline, all patients completed an MSK questionnaire and underwent a detailed physical examination, including tender and swollen joint counts and evaluation of enthesitis with the Leeds Enthesitis Index. Blood tests including inflammatory markers were collected. Patients with MSK abnormalities underwent X-ray, MRI, or ultrasound as clinically appropriate.Participants were then categorised based on all available clinical and imaging data into:Pso-only,Pso+: MSK findings insufficient for PsA diagnosis,PsA (CASPAR),Other rheumatic disease.

Results: A total of 141 patients were included. The cohort consisted of 82 males (58.1%), with a mean age of 42.3 ± 14.5 years and a mean Pso duration of 5.8 ± 2.7 years.Psoriatic nail involvement (pitting, ridging, or onycholysis) was present in 96 patients (68%).Fifty-nine patients (41.8%) had no MSK manifestations, while 82 patients (58.2%) demonstrated at least one MSK sign or symptom at baseline.Based on complete assessment, patient distribution was:Pso-only: 41%Pso+: 35%PsA meeting CASPAR criteria: 21.8%Other rheumatic disease: 2–3%

Conclusions: In this early psoriasis cohort, more than half of the patients exhibited MSK abnormalities at baseline, and approximately one in five already met CASPAR criteria for PsA. These findings reinforce the importance of early and systematic MSK evaluation in psoriasis, as this subgroup may be at increased risk of progression to psoriatic arthritis. Longitudinal follow-up will help identify features most predictive of PsA development.

Table 1. Baseline Characteristics and Musculoskeletal Findings in the Psoriasis Cohort (N = 141)

Variable	Results
Total patients included	141
Male (%)	82 (58.2%)
Mean age (years)	43.2 ± 13.9
Mean Psoriasis duration (years)	5.8 ± 3.1
Psoriatic nail disease	98 (69.5%)
No musculoskeletal signs or symptoms	61 (43.3%)
At least one MSK finding	80 (56.7%)
• Pso only	60 (42.5%)
• Pso+ (MSK signs/symptoms insufficient for PsA)	30 (21.3%)
• PsA (CASPAR criteria)	31 (21.8%)
• Other rheumatic disease	20 (14.1%)

P138

INFECTIOUS COMPLICATIONS AND ASSOCIATED RISK FACTORS IN AXIAL SPONDYLOARTHRITIS TREATED WITH BIOLOGIC AGENTS: A PROSPECTIVE REAL-WORLD COHORT STUDY

A. Djebbari[1], A. Gouder[2]

[1]HMRU rheumatology, Constantine, Algeria; [2]HMRU RHEUMATOLOGY, Constantine, Algeria

Objective To evaluate the occurrence of infections and identify associated risk factors in patients with radiographic axial spondyloarthritis (r-axSpA) treated with biologic disease-modifying antirheumatic drugs (bDMARDs) in a real-world clinical setting.

Methods This prospective observational cohort study included 23 patients with r-axSpA who initiated or switched biologic therapy between December 2020 and December 2023. Patients were followed longitudinally for the occurrence of infections, classified according to organ system and severity. Infection incidence rates were calculated per

1000 person-years (PY). Cox proportional hazards regression analysis was performed to identify factors associated with the first infectious event.

Results The 23 patients contributed a total of 78.4 PY of follow-up. During the observation period, 3 patients experienced at least one infectious episode, corresponding to an overall infection rate of 33.3 events per 1000 PY. Respiratory tract infections were the most frequent (22/1000 PY), followed by herpes zoster (10.8/1000 PY). Multivariate analysis identified older age, female sex, diabetes mellitus with complications, and chronic kidney disease as factors associated with increased infection risk. Male sex appeared to be protective against infection occurrence.

Conclusion In this small real-world cohort of patients with r-axSpA treated with biologic agents, infections were relatively infrequent but predominantly involved the respiratory tract. Certain comorbidities and demographic factors were associated with a higher risk of infection. These findings highlight the importance of careful infection risk assessment and monitoring, particularly in vulnerable patients receiving biologic therapy.

Table 1. Baseline Characteristics of the Study Population (n = 23)

Variable	Value
Age, mean ± SD (years)	41.6 ± 11.2
Male sex, n (%)	15 (65.2)
Disease duration, median (IQR), years	6.8 (3.2–11.4)
Peripheral arthritis, n (%)	7 (30.4)
Ischemic heart disease, n (%)	3 (13.0)
Diabetes mellitus (with complications), n (%)	4 (17.4)
Chronic kidney disease, n (%)	2 (8.7)
Type of biologic therapy	
– TNF inhibitors, n (%)	18 (78.3)
– IL-17 inhibitors, n (%)	5 (21.7)

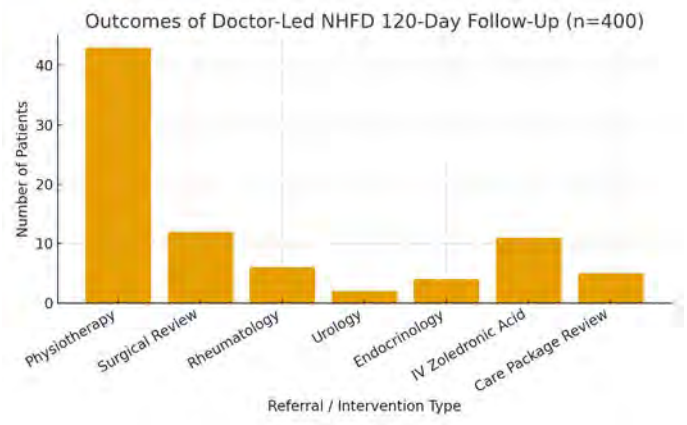
Table 2. Incidence and Types of Infections During Follow-Up

Infection Type	Number of Events	Incidence Rate (/1000 PY)
Upper/lower respiratory tract infections	2	21.5
Herpes zoster	1	11.8
Other infections	0	0
Total infections	**3**	**33.3**

P139

ENHANCING THE NHFD 120-DAY FOLLOW-UP: A DOCTOR-LED MODEL COMPLEMENTING NURSING AND AUDIT STANDARDS — A LOCAL EXPERIENCE FROM A UK ORTHOGERIATRIC SERVICE

A. E. Elsalamwy[1], S. Z. Zidan[2], H. H. Hussein[1]



[1]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-sea, United Kingdom; [2]Trauma & Orthopaedic Department, North Middlesex University Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom

The National Hip Fracture Database (NHFD) 120-day follow-up is a well-established national standard designed to monitor recovery, function, and secondary prevention in patients with hip and other fragility fractures. Across the United Kingdom, this process is usually coordinated by highly skilled nursing or administrative staff using a structured questionnaire, providing essential audit data and ensuring national consistency and governance. This approach forms the backbone of post-fracture outcome monitoring and has been instrumental in improving hip fracture care standards nationwide.

At our institution, we explored whether incorporating orthogeriatric medical oversight could add further clinical value while maintaining full alignment with NHFD principles and recognising the vital contribution of the nursing team. Over a 12-month period, an orthogeriatric doctor conducted the 120-day follow-up calls for 400 consecutive patients, using the standard NHFD dataset supplemented by a concise clinical review focusing on pain, mobility, wound status, and new symptoms.

This model demonstrated meaningful additional clinical impact. Forty-three patients (10.8%) required re-referral to physiotherapy, despite previous rehabilitation input. Twelve patients (3%) required surgical reassessment, including three implant failures after dynamic hip screw fixation and one common peroneal nerve injury. Additional referrals included six to rheumatology, two to urology, four to endocrinology, and five for care package review. Furthermore, 11 patients initiated intravenous zoledronic acid after initially deferring treatment. Overall, approximately 20% of patients benefited from new or modified management as a direct result of the enhanced clinical component.

This experience suggests that a collaborative model, in which the established nurse-led NHFD follow-up is complemented by targeted medical input, can enhance post-discharge safety, facilitate early detection of complications, and strengthen secondary prevention. Respecting NHFD standards, this hybrid approach demonstrates how clinical engagement can transform an audit process into a proactive tool for improving patient outcomes.

(Figure 1 illustrates the distribution of referrals and interventions resulting from the 120-day reviews.)

P140

BRIDGING THE BONE HEALTH GAP: THREE YEARS OF HIP FRACTURE ADMISSIONS AND NATIONAL TRENDS IN OSTEOPOROSIS MANAGEMENT (UK, 2022–2024) LOCAL EXPERIENCE

A. E. Elsalamwy[1], E. I. Zeinelabdein[2], H. H. Hussein[1], S. Z. Zidan[3]

[1]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-sea, United Kingdom; [2]Emergency Department, Southend on sea, United Kingdom; [3]Trauma & Orthopaedic Department, North Middlesex University Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom

Background Osteoporosis remains a major global contributor to morbidity and mortality in older adults. Hip fractures, in particular, represent a sentinel event signalling underlying skeletal fragility and the need for immediate secondary prevention. Although robust trial evidence confirms that antiresorptive therapy—particularly bisphosphonates and denosumab—reduces refracture risk and mortality, real-world implementation of these treatments remains inconsistent.

In the United Kingdom, several national audits, including the **Fracture Liaison Service Database (FLS-DB)** and **National Hip Fracture Database (NHFD)**, have highlighted a persistent treatment gap over the past decade. Recent publications, such as the **five-nation consensus on post-hip-fracture zoledronate use (Johansen et al., Age & Ageing 2023)**, and the **FLS-DB Annual Reports (2022–2025)**, collectively emphasise that fewer than one in ten patients are on active bone-protective therapy when admitted with a hip fracture. This study aimed to evaluate our local data over three years in comparison with these national benchmarks.

Methods We conducted a retrospective review of **914 consecutive patients** admitted with femoral fractures between **January 2022 and December 2024** at a large district general hospital in the United Kingdom. All cases were recorded in the **National Hip Fracture Database (NHFD)**. Pre-fracture medication data were extracted from admission records to determine ongoing use of antiresorptive agents (alendronic acid, risedronate, or denosumab) and calcium / vitamin D supplementation. Descriptive statistics were compared with national results from the **FLS-DB reports (2021–2023)** to identify alignment or divergence from national trends.

Results

Of the 914 patients analysed (mean age 82 years; 71 % female):

- **44 (4.8 %)** were on **alendronic acid**,
- **6 (0.7 %)** on **denosumab (Prolia)**,
- **182 (19.9 %)** on **calcium + vitamin D only**, and
- **694 (75.9 %)** received **no bone-protective therapy** at the time of fracture.

Overall, **5.5 %** of patients were on active antiresorptive therapy, broadly consistent with the **8–10 % national average** reported by the FLS-DB for the same period. These findings mirror UK data indicating that, despite widespread awareness of osteoporosis management guidelines, real-world uptake of preventive therapy remains limited. Importantly, the data show **no regression** in treatment coverage compared with national figures, suggesting stability rather than deterioration.

Discussion

Our results support the continuing presence of a national bone health treatment gap but also demonstrate **alignment with UK benchmarks**, highlighting the consistency of this challenge across services rather than any local deficiency. The findings should be interpreted as a **shared opportunity** to strengthen secondary prevention through improved pathways, rather than as criticism of existing practice.

The observed gap likely reflects a combination of factors recognised in prior UK publications: limited persistence with oral bisphosphonates, under-referral to Fracture Liaison Services, and reliance on calcium / vitamin D monotherapy. Encouragingly, national initiatives such as **in-hospital intravenous zoledronic acid programmes** and **enhanced FLS integration** are now addressing these barriers. Embedding these interventions locally could accelerate progress.

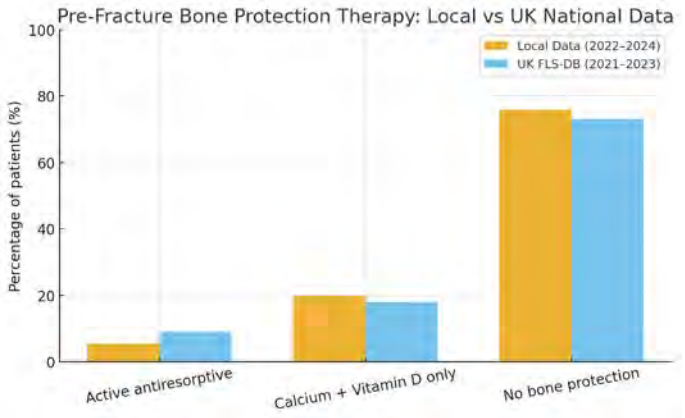

Figure 1. Pre-fracture bone protection therapy: Local (2022–2024) vs UK FLS-DB (2021–2023)

Conclusion

This three-year review confirms that most patients admitted with hip fracture remain untreated for osteoporosis, yet the similarity to national figures demonstrates a **systemic, not isolated**, gap. By leveraging existing national guidance and proven interventions—early intravenous zoledronate, coordinated FLS follow-up, and improved communication with primary care—there is substantial potential to convert awareness into action.

Our experience underscores the power of shared data and collaboration: by viewing each hip fracture admission as an opportunity for preventive care, we can collectively move closer to the IOF's vision of eliminating preventable fragility fractures.

P141

COGNITIVE IMPAIRMENT AND EQUITY IN HIP-FRACTURE CARE: A RETROSPECTIVE COHORT STUDY WITHIN A MODERN ORTHOGERIATRIC PATHWAY

A. E. Elsalamwy[1], G. M. Mathew[2], A. E. Elagil[3], E. G. Gangwani[4]

[1]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Westcliff-on-Sea, Essex, UK., Southend- on-sea, United Kingdom; [2]Anaesthesia Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Westcliff-on-Sea, Essex, UK., Southend on sea, United Kingdom; [3]Emergency Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Westcliff-on-Sea, Essex, UK., Southend on sea, United Kingdom; [4]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend- on-sea, United Kingdom

Background: Cognitive impairment—including dementia and delirium—is common among hip fracture patients and may influence peri-operative processes and outcomes. Despite standardised national pathways, it remains unclear whether cognitively impaired patients receive equitable care. We evaluated differences in surgical timing, multidisciplinary management, and discharge outcomes between patients with and without cognitive impairment treated within a modern orthogeriatric service.

Methods: We retrospectively reviewed a random sample of 382 consecutive patients aged ≥60 years admitted with fragility hip fracture to Southend University Hospital, UK (January 2024–June 2025). Patients were stratified into cognitively impaired (dementia, suspected cognitive decline, or delirium on admission; *n*=191) and non-impaired (*n*=191) groups. Data were abstracted from the National Hip Fracture Database and hospital records on time to surgery, orthogeriatric review, early physiotherapy and mobilisation, analgesia, communication and carer involvement, DNACPR documentation, discharge destination, and in-hospital mortality. Between-group comparisons used *t*/Mann–Whitney and χ^2 tests ($p<0.05$).

Results: Impaired patients experienced longer delays to theatre (median 35.3 h [IQR 23.0–48.7] vs 29.8 h [20.6–43.8]; $p=0.029$), although time to orthogeriatric review was similar (~21 h). Early mobilisation by postoperative day 2 was less frequent among impaired patients (81.6% vs 89.9%, $p=0.04$). Analgesic prescribing was comparable, but qualitative review indicated undertreatment in cognitively impaired patients. Discharge home occurred less often in impaired patients (52.7% vs 84.4%, $p<0.001$); institutional care was more common (35.3% vs 7.5%), and in-hospital mortality was higher (8.7% vs 2.7%, $p=0.02$).

Conclusions: Even within a standardised orthogeriatric pathway, patients with cognitive impairment experienced slower access to theatre, reduced early mobilisation, lower rates of discharge home, and higher in-hospital mortality. These inequities appear driven by modifiable processes—consent logistics, analgesia delivery, and mobilisation under delirium. Dementia-informed adaptations, including fast-track surgical prioritisation, validated pain-assessment tools, delirium-prevention bundles, and strengthened rehabilitation, are warranted to deliver truly equitable hip-fracture care.

Keywords: Hip fracture; dementia; delirium; cognitive impairment; orthogeriatric care; surgery delay; mobilisation; mortality; equity.

P142

NEW ONSET NEUROLOGICAL MANIFESTATIONS AFTER COVID VACCINE: COINCIDENCE OR ASSOCIATION?

S. Raafat[1], N. Badr[1], A. Elzohiery[1], S. Galal[1]

[1]Faculty of Medicine Ain Shams university, Cairp, Egypt

Objectives : Following the COVID-19 virus epidemic , vaccines were considered the best way to achieve collective safety and control mortality. Unfortunately ,they had the potential to induce a plethora of peripheral nervous system diseases. Though there were variable types of COVID-19 vaccines, most of them produced immunological complications through the same mechanism of molecular mimicry. The aim of this study was to detect any possible de-novo peripheral neurological complications among a sample of COVID-19 vaccinated patients.

Patients and methods : Twenty-five reported cases of peripheral nervous system (PNS) affection manifesting after receiving COVID-19 vaccines were enrolled in this study, ten (40%) of them were females and 15 (60%) were males. All participants underwent thorough clinical neurological and electrodiagnostic assessment . Motor and sensory nerve conduction studies for both upper and lower limbs were done ,as well as delayed responses (F and H studies) and needle EMG when needed.

Results : The participants ages ranged from 18 – 72 years with mean 40.24 ± 17.06. About 13 (52%) of the vaccinated participants were previously infected by coronavirus within median time 330 (180 - 540) days , yet with no statisical significant difference between previously infected and non infected cases as regrds electrodiagnostic findings . The majority of the patients received AstraZeneca vaccine (n = 15, 60 %) while the rest of the patients received Pfizer-BioNTech vaccine (n = 5, 20 %), Sinopharm vaccine (n = 3, 12 %) as well as Johnson & Johnson vaccine (n = 2, 8 %). Affected individuals usually presented following the first dose 16 (64%). with latency period before the neurological symptoms' onset ranging from 7 to 21 days with mean of 15.4 ± 5.47 days . Furthermore, the results indicated that, the most frequently reported symptom was paresthesia , followed by weakness(Table 1). The neurological manifestations severity were higher after the AstraZeneca vaccine .Several electrodiagnostic manifestations of PNS affection were observed, but the Guillain–Barre Syndrome (GBS) was of higher incidence (48%), followed by sensory demelyinating polyneuropathy (20%).

Table 1:Neurological symptoms after different Covid vaccines:

	Vaccine type				Fisher's Exact test of significance (FE)	
	Johnson & Johnson	AstraZeneca	Pfizer BioNTech	Sinopharm		
	N:2 (%)	N:15 (%)	N:5 (%)	N:3 (%)	p-Value	Significance
Paresthesia	2 (100%)	6 (40%)	3 (60%)	2 (66.7%)	0.534	NS
Weakness	1 (50%)	**11 (73.3%)**	0 (0%)	0 (0%)	0.002	**S**
Hypoesthesia	0 (0%)	7 (46.7%)	2 (40%)	1 (33.3%)	0.908	NS

Fisher's Exact test of significance (FE) P- value: level of significance -P> 0.05: Non-significant (NS) -P< 0.05: Significant (S)

Percentage (%) Number (N)

Conclusion:

COVID-19 vaccination are linked to newly reported neurological symptoms mainly paresthesia and weakness ,yet still, they appeared to be rare considering the total number of vaccines administered. The pathogenesis of manifesting those neurological disorders remains unclear, and more in-depth studies are needed to clarify current hypotheses and provide additional evidence.

BONE MORPHOGENETIC PROTEIN-2: A POSSIBLE MARKER IN PRIMARY KNEE OSTEOARTHRITIS

N. El Kadery[1], H. Khaled[1], A. Elzohiery[1], M. Raafat[1]

[1]Faculty of Medicine Ain Shams university, Cairo, Egypt

Introduction:
Many different factors contribute to the onset and progression of OA. The bone morphogenetic proteins (BMPs), that are subsets of the (TGF-ß) superfamily, stimulate production of extracellular matrix components by chondrocytes and have the ability to counteract catabolic cytokines like interleukin 1 (IL-1).
Aim of the work:
The aim of this study was to investigate the role of plasma BMP-2 in primary knee osteoarthritis and its relation to disease severity.
Patients and Methods:
The study included 30 patients with primary knee O.A and ten apparently healthy matched individuals as a control group. Plasma levels of BMP-2, radiological severity of the disease, pain intensity as well as, assessment of functional status using the Western Ontario and McMaster University Osteoarthritis Index (WOMAC) were done.
Results:

• Plasma levels of BMP-2 were significantly higher in patients than in control group.

• Patients with palpable osteophytes have the highest BMP-2 levels.

• A strong positive correlation was found between plasma levels of BMP-2 and each of: radiological severity, disease duration and WOMAC score.

In conclusion : BMP-2 levels correlate with radiographic severity of O.A. which make such biomarker measurement may not only act as a substitute marker for the disease ,but also has the potential to contribute to the fundamental processes underlying the pathogenesis of O.A.

P144

TARGETING CERVICAL MYOFASCIAL PAIN SYNDROME : DRY NEEDLING OR ULTRASOUND ?

A. Elzohiery[1], H. Agamy[1], N. El Kadery[1], M. Arafa[1]

[1]Faculty of Medicine Ain Shams university, Cairo, Egypt

Background : Myofascial pain syndrome (MPS) is a complex pain syndrome characterized by myofascial trigger points (MTrPs) in skeletal muscles. Ultrasound (US) therapy is one of the main devices used in physical therapy, for the treatment of MTrPs in MPS. Dry needling is skilled technique also used in the treatment of MTrPs in MPS.
Aim of the work: This study aimed to compare the effect of dry needling with the effect of ultrasonic waves in the treatment of cervical myofascial pain.
Patients and methods : a sample of 30 patients with myofascial trigger points in trapezius muscle was randomly chosen and divided into 2 groups each contains 15 patients. The first group was treated by ultrasonic waves in a pulsed mode (1MHz, 1W/cm², 1:1 ratio) 5 min to each trigger point .The second group was treated with deep filliform acupuncture dry needling diameter 0.25 mm (peppering technique) to each trigger point with a rate of 3 times per week for 3 weeks.
Results: All patients showed significant improvement ($P > 0.001$) immediately after treatment period with disappearance of trigger points, increasing in cervical ROM and decreasing in VAS ; but 3 weeks later trigger points reappeared, ROM decreased and VAS increased again.
Conclusion: Both US waves and dry needling are safe and effective techniques in treating cervical myofacial pain syndrome.The needling showed no superiority over US and it still considered invasive.We can spare using dry needling to patients who have contradindications to US therapy such as patients with pacemaker ,metal implants or for areas with growing bones or healing fractures .

P145

EFFECT OF PREOPERATIVE BISPHOSPHONATE THERAPY ON BONE MINERAL DENSITY IN PATIENTS WITH PHPT ONE YEAR AFTER PARATHYROIDECTOMY

A. Pershina-Miliutina[1], A. Eremkina[1], I. Ozhimalov[1], A. Gorbacheva[1], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: Parathyroidectomy [PTE] is the optimal strategy for primary hyperparathyroidism [PHPT]. But in some cases, conservative treatment, including bisphosphonates [BPh], can be used. The question 'can preoperative BPh therapy affect bone recovery following PTE' - remains unresolved.
The aim of this study was to evaluate the impact of preoperative BPh therapy on changes in bone mineral density [BMD] one year after PTE, as measured by both DXA and 3D-DXA.
Materials and methods: We included 25 patients (1 man, 24 women) receiving BPh before surgery. The median duration of BPh receiving was 15 months. The median duration of DXA before and after surgery was 1 year. A control group without BPh therapy (matched for gender, age, and baseline BMD values at 3 sites) was selected using the matched

pair method. 3D-DXA analysis was performed using 3D-Shaper v.2.14 software. The statistical analysis – using the R language and the Statistica v.13 software package.
Results: At disease onset, both groups had comparable calcium-phosphorus metabolism parameters, except for elevated β-CTx levels in the non-BPh group (p<0.001). The trend towards statistically significant differences was observed in the levels of phosphorus (p=0.0036), alkaline phosphatase (p=0.014) and osteocalcin (p=0.001), each of which was higher in the non-BPh group. No differences were observed in 3D-DXA parameters pre-surgery.
In the BPh group, significant BMD improvements were observed only in the lumbar spine [LS] (p<0.001), and in the volume of trabecular bone at the total hip [TH] (p=0,001). Conversely, in the non-BPh group, BMD increased substantially at the LS, TH (both p<0.001), and femoral neck [FN] (p=0.001). 3D-DXA revealed increases in cortical bone density at the TH (p=0.001) and in the volume of trabecular bone at the TH and FN (p<0.001).
Post-surgery, both groups showed comparable BMD increases in key skeletal regions at the femur. However, 3D-DXA revealed trends toward higher increases in cortical bone thickness in the non-BPh group.
Conclusion: 3D-DXA provides insights into cortical and trabecular bone structure, crucial for fracture risk prediction in PHPT patients. Preoperative BPh therapy may negatively affect post-PTE BMD recovery, particularly in cortical bone. Further research is required.

P146

PROGNOSTIC VALUE OF THE C-REACTIVE PROTEIN/ALBUMIN RATIO IN MULTIPLE MYELOMA

A. Farah[1], Z. Gassara[1], C. Zayani[1], M. Ezzedine[1], M. H. Kalel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, CHU Hedi Chaker, Sfax, Tunisia, Sfax, Tunisia

Introduction: Multiple myeloma (MM) is a malignant plasma cell disorder with chronic inflammation affecting disease progression and prognosis. C-reactive protein (CRP) reflects inflammation, while serum albumin indicates nutritional status. The CRP/albumin ratio (CAR) is a simple prognostic biomarker in several cancers, but its role in MM remains unclear. This study evaluated the association between CAR at diagnosis and prognosis.
Patients and methods: This retrospective observational study included 55 patients diagnosed with MM in a rheumatology department between January 2010 and December 2025. Demographic, clinical, and biological data were collected. The CAR was calculated, and patients were stratified into two groups: low CAR (≤ 0.5) and high CAR (> 0.5). Outcomes assessed included clinical status, mortality, and complications. A p-value < 0.05 was considered statistically significant.
Results: The mean age at diagnosis was 65.2 ± 10.9 years, with a male predominance (34 men, 61.8%; 21 women, 38.2%). Impaired general condition (performance status ≥ 2) was observed in 29 patients (52.7%). CRAB features were frequent : bone involvement (49 patients, 89.1%), anemia (26 patients, 47.3%), hypercalcemia (15 patients, 27.3%), and renal impairment (12 patients, 21.8%). Mean serum albumin was 33.8 ± 5.2 g/L, with hypoalbuminemia (< 35 g/L) in 31 patients (56.4%). Mean CRP was 37.7 ± 37.1 mg/L, and mean CAR was 1.15 ± 1.05 (low 28, 50.9%; high 27, 49.1%). Fourteen patients (25.5%) were eligible for intensive treatment, while 41 (74.5%) were not. During follow-up, 29 patients (52.7%) died. A high CAR was significantly associated with poorer general condition (p = 0.045), ineligibility for intensive treatment (p = 0.03), higher mortality (p = 0.048), and more complications (p = 0.029), particularly infections (p = 0.02). Associations with anemia (p=0.08) and renal impairment (p=0.09) were not significant. CAR was not correlated with age at diagnosis (p = 0.62).
Conclusion: The CAR is a simple, clinically relevant biomarker for prognostic stratification in MM. High CAR predicts poor general condition, ineligibility for intensive treatment, higher mortality, and more complications. Incorporating CAR may help identify high-risk patients early and guide personalized management.

P147

ROLE OF IMAGING IN EARLY DETECTION AND PROGNOSTIC STRATIFICATION OF MULTIPLE MYELOMA IN RHEUMATOLOGY PRACTICE

A. Farah[1], Z. Gassara[1], C. Zayani[1], M. Ezzedine[1], M. H. Kalel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, CHU Hedi Chaker, Sfax, Tunisia, Sfax, Tunisia

Introduction Bone involvement is a hallmark of multiple myeloma (MM) and a common presentation in rheumatology. Imaging is essential for diagnosis, assessment of skeletal involvement, and prognostic evaluation. This study evaluated the diagnostic yield of conventional radiography and MRI, and the association between radiological lesions and ISS stage.
Patients and methods This retrospective observational study included 55 patients with MM followed in a rheumatology department. Radiological data at diagnosis and the International Staging System (ISS) score were analyzed. The diagnostic performance of conventional radiography and MRI was assessed, and the association between bone involvement on MRI and prognosis, as reflected by the ISS score, was examined. A p-value < 0.05 was considered statistically significant.
Results Conventional radiographs (skull, spine, pelvis, rib cage, and long bones) were performed in 52 patients (95%) and were normal in 10 (19%). Abnormalities included punched-out lesions (22, 42%), vertebral compressions (28, 54%), long bone fractures (9, 17%), diffuse demineralization (12, 23%), and multiple lesions (21, 40%). Whole-body MRI including spine and pelvis was performed in 40 patients (73%) and revealed multiple lesions (29, 73%), vertebral compressions (24, 60%), fractures (5, 13%), plasmacytomas (18, 45%), neurological involvement (9, 23%), epiduritis (8, 20%), and marrow replacement (11, 28%). Among 10 patients with normal radiographs, MRI detected lesions in 8 (80%), including 5 without CRAB criteria. Regarding the ISS score, patients were distributed as follows: stage I, 22 patients (40%); stage II, 19 patients (34.5%); stage III, 14 patients (25.5%). Extensive MRI involvement (multiple lesions and/or plasmacytomas) was significantly associated with higher ISS (II–III) (p = 0.04).
Conclusion Conventional radiography has limited diagnostic yield in initial MM evaluation. Whole-body MRI is the most effective modality for early detection of bone and marrow lesions, especially in patients with normal radiographs and no CRAB criteria. MRI extent correlates with ISS stage, supporting its central role in diagnosis and prognostic stratification in rheumatology practice.

P148

ASSOCIATION BETWEEN RADIOLOGICAL FINDINGS AND PAIN IN LUMBAR SCIATICA

A. Farah[1], Z. Gassara[1], M. Ezzedine[1], A. Feki[1], S. Ben Jmeaa[1], M. H. Kalel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, CHU Hedi Chaker, Sfax, Tunisia, Sfax, Tunisia

Introduction Lumbar sciatica is a common cause of pain and functional limitation. While imaging identifies structural lesions, the relationship between radiological findings and clinical severity remains unclear. This study aimed to assess the correlation between lumbar imaging findings and pain in patients with common lumbar sciatica.

Patients and methods This retrospective observational study included 95 patients followed in a rheumatology department for lumbar sciatica between January and December 2025. Clinical data included pain intensity (VAS), functional limitation (Oswestry Disability Index, ODI), and signs of radiculopathy (Lasègue, and Sonnette) as well as the Schöber index. Imaging included standard lumbar radiographs and spinal MRIs. For statistical analysis, a p-value < 0.05 was considered significant.

Results: The mean age was 68 ± 14.7 years, with a male-to-female ratio of 0.77. A history of previous low back pain was reported in 47 patients (58.7%). Mean VAS was 6.7 ± 1.4/10, and mean ODI was 40 ± 11%. Neurological signs included a positive Lasègue in 35 patients (36.9%) and a positive "Sonnette" in 28 patients (29.5%). The mean Schöber index was 3.5 ± 0.9 cm. On standard lumbar radiographs, disc space narrowing was observed in 48 patients (50.5%), signs of lumbar canal stenosis in 25 (26.3%), facet arthrosis in 38 (40%), and spondylolisthesis in 12 (12.6%). Spinal MRI revealed nerve root compression in 32 patients (33.7%), disc protrusions in 40 (42.1%), foraminal stenosis in 22 (23.2%) and degenerative disc changes in 45 (47.4%). Nerve root compression on MRI was significantly correlated with higher VAS (p = 0.001) and ODI (p = 0.035), whereas abnormalities detected only on standard radiographs showed no correlation.

Conclusion : Nerve root compression detected on spinal MRI correlates significantly with pain intensity and functional limitation in patients with lumbar sciatica, whereas standard radiographs are poorly predictive. MRI is therefore a valuable tool for identifying structural causes of radicular pain and guiding management, especially in patients with severe or persistent symptoms.

P149

LISTENING TO PATIENTS: SATISFACTION AND EXPERIENCE IN A RHEUMATOLOGY DAY CARE UNIT

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background :
The rheumatology day care unit (RDCU) is an essential component of patient management, providing monitoring and administration of biological therapies, bisphosphonate infusions, and intra-articular injections. Assessing patient satisfaction and feedback is therefore crucial to improving the quality of care.
Objective :To evaluate patients' satisfaction with the functioning of the RDCU and to identify the factors associated with the level of satisfaction.
Method : A 13 item questionnaire was administered to all patients attending the RDCU from 12 January to 24th . Patient satisfaction was assessed using a a visual analogue scale (0-100, 0 meaning completely unsatisfied, 100 meaning completely satisfied). Further information was collected on conditions of the RDCU, including waiting time, satisfaction with the role of medical and nursing staff (satisfaction level with their friendliness, question answering, care delivery, privacy during consultation, clarity of the given information) using a 5-point Likert scale (1 : completely unsatisfied to 5 : totally satisfied).
Results : In total, 33 patients were included with a mean age of 59.6 ± 14.7 years and 69,7% were female. Patients consulted for the following : biologic therapy administration (n :14 , 42,4 %), bisphosphonate infusions (n :8 , 24,2 %), and intra articular injections (n : 11, 33,4 %).
The mean level of satisfaction with the RDCU was 88 ± 9,7. Regarding waiting time, 15 (45,5%) of patients were totally satisfied while 1 (3%) were totally unsatisfied. However, 8 (88 %) of patients admitted for intra articular injections were totally unsatisfied while 3 were totally satisfied. 66,7 % of patients were very satisfied with the cleanliness of the unit , 72,7 % were totally satisfied with the comfort . 97% were very satisfied with the friendliness of the staff and 93,9% were very satisfied by their question answering and clarity of given informations . 84,9 % were very staisfied by the quality of cary delivery and privacy during conusltation.
Overall, most patients reported high levels of satisfaction with the quality of care provided . Very high satisfaction was observed regarding the staff's friendliness ,the privacy respect and unit conditions . Waiting time was also positively rated, particularly among patients receiving intravenous treatments. In contrast, patients attending the unit for intra-articular injections reported lower satisfaction levels, with waiting time being the main source of dissatisfaction.
Conclusion : Patients were overall very satisfied with the functioning of the RDCU , particularly with the quality of care and staff professionalism . However, waiting time emerged as an area for improvement . Targeted organizational adjustments could further enhance patient satisfaction and optimize the functioning of the RDCU.

P150

SJÖGREN'S SYNDROME: MORE PRONOUNCED ARTICULAR INVOLVEMENT IN SERONEGATIVE FORMS

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background:
Sjögren's syndrome (SS) is an autoimmune disease that may present with articular involvement, often influenced by the immunological profile. Specific autoantibodies, particularly anti-SSA/SSB, are traditionally associated with distinct phenotypes; however, their impact on articular manifestations remains controversial.
The aim of this study was to compare the characteristics of articular involvement between patients with and without specific autoantibodies.
Methods:
We conducted a monocentric retrospective study including patients followed for SS defined according to the 2016 ACR/EULAR classification criteria between 2000 and 2024. Patients were divided into two groups: G1, seronegative patients, and G2, seropositive patients.
The characteristics of articular involvement were compared between the two groups.

Results:
A total of 48 patients were included, all female. The mean age was 63.15 ± 8.06 years in G1 versus 56.64 ± 11.23 years in G2 (p = 0.032). Articular involvement was present in 100% of patients in G1 compared with 89.28% in G2 (p = 0.136). Isolated inflammatory arthralgia was the most frequent manifestation, observed in 65% of G1 and 71.42% of G2 patients (p = 0.344). Arthralgia involved both large and small joints without a specific predilection in 65% of G1 versus 39.28% of G2 patients (p = 0.307).

The mean number of nocturnal awakenings was significantly higher in G1 (1.25 ± 1.48) compared with G2 (0.10 ± 0.41; p < 0.001). The mean duration of morning stiffness was longer in G1 (21.75 ± 26.17 minutes) than in G2 (6.25 ± 9.77 minutes; p = 0.006). Patients in G1 had a higher mean number of tender joints (6.85 ± 6.32 vs 3.96 ± 3.50 in G2; p = 0.049). The mean number of swollen joints was 1.35 ± 4.48 in G1 versus 0.32 ± 0.98 in G2 (p = 0.245). The mean patient global assessment was 5.85 ± 1.85 in G1 compared with 5.29 ± 1.56 in G2 (p = 0.552). The mean DAS28-CRP was 3.55 ± 0.63 in G1 versus 3.24 ± 0.70 in G2 (p = 0.156), and the mean DAS28-ESR was 4.34 ± 0.68 in G1 versus 4.32 ± 0.88 in G2 (p = 0.96).
Conclusion:
Articular manifestations are frequent in both forms of Sjögren's syndrome. However, articular involvement appears to be more severe in seronegative patients, particularly with regard to nocturnal awakenings, duration of morning stiffness, and number of tender joints.

P151
SEROPOSITIVE AND SERONEGATIVE PRIMARY SJÖGREN'S SYNDROME: A SHARED CLINICAL PHENOTYPE

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background:
Primary Sjögren's syndrome (pSS) is a heterogeneous autoimmune disease that may be associated or not with the presence of anti-SSA/Ro and/or anti-SSB/La autoantibodies. So-called "seropositive" forms, characterized by the presence of anti-SSA/SSB antibodies, are classically associated with an increased risk of systemic manifestations. This study aimed to compare the frequency and nature of systemic manifestations between seropositive and seronegative patients.
Methods:
We conducted a monocentric retrospective study including patients followed for pSS defined according to the 2016 ACR/EULAR classification criteria. Patients were divided into two groups according to their immunological profile: G1, seronegative patients, and G2, seropositive patients.
For each group, systemic manifestations were collected from medical records between 2000 and 2024.
Results:
A total of 48 patients were included, all female. The mean age was 63.15 ± 8.06 years in G1 versus 56.64 ± 11.23 years in G2 (p = 0.032). Lymph node involvement was observed in 10% of patients in G1 and 10.71% in G2 (p = 0.938). Pulmonary involvement was reported in 35% of patients in G1 compared with 46.42% in G2 (p = 0.439). Cardiac involvement was present in 10% of G1 patients versus 7.14% in G2 (p = 0.731). Renal involvement was diagnosed in 5% of patients in G1 compared with 17.82% in G2 (p = 0.192). Cutaneous involvement was present in 15% of G1 patients versus 32.14% in G2 (p = 0.184). Neurological involvement was identified in 15% of patients in G1 and 25% in G2 (p = 0.411).
Conclusion:

In our study, a wide spectrum of systemic manifestations was observed. However, their frequency and nature were comparable between seropositive and seronegative forms of primary Sjögren's syndrome.

P152
IMPACT OF IMMUNOLOGICAL PROFILE ON BIOLOGICAL PARAMETERS IN PRIMARY SJÖGREN'S SYNDROME

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background:
Primary Sjögren's syndrome (pSS) is an autoimmune connective tissue disease classically associated with the presence of anti-SSA/Ro and/or anti-SSB/La autoantibodies. However, a subgroup of patients may lack specific serological markers and are referred to as "seronegative." Some studies have reported a higher frequency of leukolymphopenia and hypergammaglobulinemia in seropositive patients [1].
The aim of this study was to compare biological parameters between seropositive and seronegative patients with pSS.
Methods:
We conducted a monocentric retrospective study including patients followed for pSS defined according to the 2016 ACR/EULAR classification criteria over a 24-year period (2000–2024). Patients were divided into two groups according to their immunological profile: G1, seronegative patients, and G2, seropositive patients.
Biological data, including complete blood count (CBC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and serum protein electrophoresis, were collected from medical records and analyzed.
Results:
A total of 48 patients were included, all female. The mean age was 63.15 ± 8.06 years in G1 versus 56.64 ± 11.23 years in G2 (p = 0.032). The mean CRP level was 7.18 ± 10.44 mg/L in G1 compared with 5.27 ± 7.28 mg/L in G2 (p = 0.469). Mean ESR was 36 ± 21.42 mm/h in G1 versus 33.22 ± 23.02 mm/h in G2 (p = 0.789). A biological inflammatory syndrome was present in 10% of G1 patients and 10.71% of G2 patients (p = 0.938).
No significant differences were observed between the two groups regarding CBC parameters: mean leukocyte count (G1: 6,855 ± 2,908/mm³ vs G2: 5,749 ± 1,932/mm³; p = 0.12), mean neutrophil count (G1: 4,118 ± 2,237/mm³ vs G2: 3,322 ± 1,381/mm³; p = 0.138), mean lymphocyte count (G1: 2,039 ± 742/mm³ vs G2: 1,835 ± 717/mm³; p = 0.344), mean platelet count (G1: 257,100 ± 97,826/mm³ vs G2: 240,107 ± 88,550/mm³; p = 0.533), and mean hemoglobin level (G1: 12.78 ± 1.51 g/dL vs G2: 12.15 ± 1.71 g/dL; p = 0.196).
Mean serum albumin levels were 41.35 ± 3.47 g/L in G1 and 40.43 ± 3.66 g/L in G2 (p = 0.457). Hypergammaglobulinemia was observed in 25% of G1 patients and 42.5% of G2 patients (p = 0.947).
Conclusion:
Our study showed no significant impact of immunological profile on biological parameters in primary Sjögren's syndrome.

P153

HEALTHCARE PATHWAY OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background: Primary Sjögren's syndrome (pSS) is an autoimmune connective tissue disease characterized by nonspecific symptoms. This may lead to delayed diagnosis and management.
The aim of this study was to evaluate the healthcare pathway of patients with pSS.
Methods: We conducted a monocentric retrospective study including patients followed for pSS defined according to the 2016 ACR/EULAR classification criteria between 2000 and 2024.
Sociodemographic data at diagnosis, disease characteristics, and healthcare pathway features were collected from patient interviews and medical records.
Results: A total of 48 patients were included, all female. The mean age was 59.35 ± 10.45 years (range 30–76). The mean age at onset of glandular symptoms was 48.5 ± 10.93 years (range 25–71). The mean age at diagnosis of Sjögren's syndrome was 51.6 ± 10.71 years (range 28–72). The mean delay between symptom onset and confirmed diagnosis was 30.02 ± 49.86 months (range 2–288).
Physicians consulted prior to referral to our department were as follows: general practitioner (92.3%), internist (23.07%), and rheumatologist (15.38%). Consultations took place in the public healthcare sector in 61.53% of cases and in the private sector in 38.46% of cases.
The number of physicians consulted before diagnosis was one in 69.3% of patients and two in 30.76%, with a mean of 1.31 ± 0.48 physicians. The number of consultations before establishing the diagnosis was one in 61.53% of patients, two in 23.07%, three in 7.69%, and more than three in 7.69% of patients.
Conclusion: The healthcare pathway of patients with primary Sjögren's syndrome is often long and complex, involving several healthcare providers before definitive diagnosis by a rheumatologist. This study highlights the need for better awareness among primary care physicians regarding the manifestations of pSS, in order to promote earlier diagnosis and appropriate management.

P154

THE MULTIPLE FACES OF SACRAL INVOLVEMENT

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background:
Sciatic pain is a frequent reason for consultation in rheumatology, most often of degenerative origin. In rare cases, it may reveal a serious underlying condition, particularly malignancy. We report two cases of sciatica secondary to sacral bone metastases, highlighting the importance of a thorough etiological workup in patients with symptoms resistant to first-line treatment.
Clinical observations:

Case 1:
A 44-year-old woman with a history of left-sided colon cancer treated surgically in 2015, followed by adjuvant chemotherapy completed in 2016, with removal of the implantable venous access device in 2024 due to prolonged remission.

She was hospitalized on December 3, 2024, for left sacroiliitis complicated by a 13-cm psoas muscle collection. Despite broad-spectrum antibiotic therapy with cefotaxime and teicoplanin, follow-up CT imaging showed progression of the collection. The patient subsequently developed a drug reaction with eosinophilia and systemic symptoms (DRESS) secondary to antibiotic therapy, leading to its discontinuation.

A sacroiliac biopsy was performed. Bacteriological analysis, including direct examination and cultures, was negative, as were multiplex bacterial PCR and *Mycobacterium tuberculosis* PCR. A surgical biopsy was subsequently carried out and revealed a metastasis from a colonic adenocarcinoma. The hypermetabolic nature of the lesion was confirmed on PET scan, with no evidence of other distant metastases. The patient was then referred to the oncology department for further management.

Case 2:
An 85-year-old man with a history of non-stented coronary artery disease was initially admitted to our department in January 2025 for management of chronic mechanical lumbosciatica, bilateral S1 distribution, more severe on the left side. Standard radiography showed features of an old L3 fracture and narrowing of the L5–S1 disc space. He received three methylprednisolone injections and physical rehabilitation without clinical improvement.

Given this atypical course, pelvic CT was performed, revealing a locally advanced soft tissue mass centered on the left sacral ala, with ill-defined lytic margins and homogeneous enhancement, without calcifications or fatty components. The lesion caused focal cortical disruption with extension into the presacral space and invasion of the left sacral foramina at S1, S2, S3, and S4 levels. It infiltrated the ipsilateral piriformis muscle, extended to the sacroiliac joint and iliac bone with cortical lysis, reached the sciatic canal, and showed intracanalar extension.

CT-guided biopsy revealed histological and immunohistochemical features consistent with sacroiliac involvement by a small-cell neuroendocrine carcinoma. Extensive investigations failed to identify the primary tumor.

Discussion:
These two cases illustrate that sciatica may be the presenting manifestation of bone metastases, even in the absence of a known malignancy. Advanced age, chronicity of symptoms, resistance to first-line treatments, and the presence of red flags should prompt further investigations, including cross-sectional imaging and biopsy when appropriate.

Conclusion:
In cases of atypical sciatica—particularly when painful, chronic, and treatment-resistant—a neoplastic origin should be considered. These cases underscore the need for a comprehensive etiological workup to avoid delays in diagnosis and management, which may significantly impact prognosis.

P155

SERONEGATIVE SJÖGREN'S SYNDROME: CLINICAL AND SOCIODEMOGRAPHIC CHARACTERISTICS

S. Rahmouni[1], A. Fayache[1], M. Hammi[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, Rabta Hospital, Tunis, Tunisia

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disease classically associated with the presence of anti-SSA/Ro and/or anti-SSB/La autoantibodies. However, a subgroup of patients presents with a suggestive clinical picture in the absence of specific serological markers.
The absence of autoantibodies may influence patient characteristics. This study aimed to describe the clinical and sociodemographic features of seronegative patients with pSS.
Methods: We conducted a monocentric retrospective study including patients followed for pSS defined according to the 2016 ACR/EULAR classification criteria between 2000 and 2024. Patients were divided into two groups according to immunological profile: G1, seronegative patients, and G2, seropositive patients.
Sociodemographic characteristics were analyzed using data extracted from medical records.
Results: A total of 48 patients were included, all female. The mean age was 63.15 ± 8.06 years in G1 versus 56.64 ± 11.23 years in G2 (p = 0.032). Postmenopausal status was observed in 90% of G1 patients compared with 82.14% in G2 (p = 0.213). The mean number of pregnancies was higher in G1 (4.5) than in G2 (2.53) (p = 0.02). Mean body mass index was 26.4 ± 5.48 kg/m² in G1 versus 25.44 ± 5.44 kg/m² in G2 (p = 0.612). The sicca syndrome began at a mean age of 51.7 ± 9.42 years in G1 compared with 46.21 ± 11.51 years in G2 (p = 0.087). pSS was diagnosed at a mean age of 54.6 ± 10.12 years in G1 versus 49.46 ± 10.78 years in G2 (p = 0.102). The mean diagnostic delay was 35.3 ± 30.47 months in G1 and 39.96 ± 60.54 months in G2 (p = 0.753).
Conclusion: The absence of autoantibodies did not result in a longer diagnostic delay in primary Sjögren's syndrome. However, seronegative patients were older at diagnosis and had a higher number of pregnancies.

P156

EVALUATION OF THE BURDEN ON CAREGIVERS OF PATIENTS OPERATED ON FOR HIP TRAUMA

A. Fekih[1], I. Haddada[2], J. Saadana[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:
Blunt hip trauma is a life-altering event for both the patient and their family. In our country, where hospital capacities are limited, patients are often discharged after a short stay. Consequently, family caregivers must manage a new disabling situation that can significantly impair their own health and well-being. Our objective is to evaluate the burden on family caregivers of patients operated on for hip trauma and to identify the factors associated with the severity of this burden.
Materials and Methods:
This was a three-month analytical cross-sectional study including caregivers of relatives operated on for hip trauma. The caregiver burden was assessed using the Zarit Burden Interview (ZBIT). Anxiety and depressive disorders were evaluated using the Hospital Anxiety and Depression Scale (HADS). Professional impact was measured via the Work Productivity and Activity Impairment Questionnaire (WPAI), and Quality of Life (QoL) was assessed using the SF-12 (12-Item Short Form Survey).
Results:
The average number of family caregivers per patient was 2 for 18 patients. Evaluation of the care burden according to the Zarit scale showed a moderate-to-severe burden in 53.3% of cases and a severe burden in 20% of cases. Regarding absenteeism, it was total for caregivers employed in the public sector. Psychological evaluation of caregivers revealed that 50% suffered from definite anxiety and depression. The SF-12 assessment showed a more pronounced alteration in the mental component score, with an average of 37.82 ±12[range: 24.92–55.90]. In univariate analysis, a significant positive association was found between the severity of the burden and the presence of anxiety-depressive disorders (p = 0.01), as well as the degree of kinship (p = 0.02). Similarly, a higher number of caregivers involved was associated with a more severe burden (p = 0.01).
Conclusion:
Given that the impact of hip trauma is immense on natural caregivers, it is essential to establish national recommendations ensuring a bio-psycho-social approach to alleviate this burden.

P157

FUNCTIONAL IMPACT OF LUMBOSCIATICA IN THE ELDERLY

A. Fekih[1], I. Haddada[2], J. Saadana[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Lumbosciatica (LS) is one of the most disabling conditions affecting the elderly. However, most research has focused on younger adults due to the significant socioeconomic consequences in that demographic. Our objective was to evaluate the functional impact of LS in elderly patients and to identify predictive factors for functional limitation.
Materials and Methods :
This was a descriptive cross-sectional study conducted at the Rheumatology Department of the Taher Sfar University Hospital in Mahdia. The study included 31 patients presenting with common lumbosciatica. Functional assessment was performed using the Quebec Back Pain Disability Scale and the Dallas Pain Questionnaire (DPQ).
Results :
The study included 31 patients (18 women) with a mean age of 68 years (range: 65–99). The average disease duration was 6.59 years (range: 3 months – 20 years).
Obesity was noted in 35.5% of patients (mean BMI of 28.97). Spinal syndrome was clinically observed in 41.9% of cases.
Pain was rated as severe (VAS ≥ 70 mm) in 22.6% of patients.
The mean Quebec score was 40.70 (range: 5–76), with 35.5% of subjects showing major functional impairment (Quebec score ≥ 50).

The LS impact was significant across several DPQ categories: Activities of Daily Living (ADL): 52.94% ; Work and Leisure Activities: 43.70% ; Anxiety and Depression: 31.61% ; and Social Interest: 27.42%
Statistical analysis showed no significant association between functional limitation and age, sex, obesity, VAS pain score, or the duration of symptoms.

Conclusion :

Lumbosciatica significantly impairs the functional capacity of elderly patients. These findings suggest that management of this population must be improved, moving beyond pain control to address overall quality of life and age-related comorbidities.

P158

MANAGEMENT OF ANKLE SPRAINS IN GENERAL PRACTICE: KNOWLEDGE AND APPLICATION OF THE OTTAWA ANKLE RULES

A. Fekih[1], I. Haddada[2], J. Saadana[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :

The Ottawa Ankle Rules (OAR) are designed to identify injuries that fall outside the scope of simple ankle sprains, thereby reducing the number of unnecessary radiological examinations. The objective of this study was to evaluate the knowledge and practical application of the Ottawa Ankle Rules among general practitioners (GPs).

Materials and Methods :

This was a prospective, descriptive cross-sectional study conducted over a one-month period. We surveyed GPs regarding the specific criteria that prompt them to prescribe X-rays for ankle trauma, as well as their therapeutic management once an ankle sprain is diagnosed. An online questionnaire was distributed via email to GPs in the Mahdia and Monastir regions (contact details provided by the Regional Medical Council), with a four-week response deadline.

Results :

Forty-seven GPs responded to the survey (34 women and 13 men), 83% of whom were under the age of 45. Regarding clinical volume, 55% saw between 1 and 5 trauma cases per week, 30% saw 5 to 10 cases, and 15% saw more than 10.
For prescription habits, radiographs were prescribed in 89.5% of cases. Among the Ottawa criteria, tenderness over the fifth metatarsal was the most frequently cited (68%), followed by functional impotence (inability to bear weight) (57%), and tenderness over the navicular bone (51%).
Notably, none of the participating GPs were familiar with the Ottawa Ankle Rules in their entirety.

Conclusion :

Despite its limitations (small sample size), our study highlights a significant gap in the daily application of the Ottawa Ankle Rules for ankle trauma. These rules have proven reliability in clinical diagnosis and are essential for reducing the incidence of unnecessary radiographs.

P159

EVALUATION OF SEXUAL QUALITY OF LIFE IN CHRONIC LOW BACK PAIN

A. Fekih[1], I. Haddada[2], J. Saadana[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :

Sexual life plays an important role in preserving a good quality of life for both patients and their partners. Chronic low back pain (CLBP), as well as other musculoskeletal disorders, can affect all activities of life, including sexual functioning. The aim of this study was to evaluate the impact of chronic low back pain on the sexual life of patients and to identify associated factors.

Materials and Methods :

This was a cross-sectional study involving 144 patients suffering from chronic low back pain. We specifically studied the relationship between CLBP and sexual quality of life using a validated questionnaire: the Sexual Quotient (SQ), which consists of 10 questions, each scored from 0 to 10, with a final total score ranging from 0 to 100.

Results :

The mean age was 53.87 years [range: 23–79]. The mean pain VAS score was 4.72 [range: 1–9]. The average duration of low back pain was 6.5 years. For the Quebec Back Pain Disability Scale, the mean score was 45.3 [range: 5–92]. The results for the Dallas Pain Questionnaire domains were as follows:

- 53.1% impact on daily activities
- 47.6% impact on work/leisure activities
- 45.0% impact on anxiety/depression
- 33.4% impact on sociability

Regarding treatment, 57.2% of patients were using analgesics, 5.5% were on NSAIDs, 20% had received local corticosteroid injections, 34% had undergone physical rehabilitation, and 4.1% had required surgery for associated refractory lumbosciatica. Regarding sexual dysfunction, 34.5% of patients reported no sexual activity, and 2.1% described their sexual life as catastrophic (SQ score < 20).

Conclusion :

Chronic low back pain significantly impairs sexual quality of life and frequently leads to the cessation of sexual activity. These results suggest that sexual health should be an integral part of the clinical assessment for CLBP. Management should be multidisciplinary, addressing not only physical pain but also the psychological and relational consequences of the disease.

P160

QUALITY OF LIFE IN CHRONIC LOW BACK PAIN AND LUMBOSCIATICA: A STUDY OF 152 TUNISIAN PATIENTS

A. Fekih[1], I. Haddada[2], J. Saadana[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Quality of Life (QoL) is a complex concept largely influenced by an individual's physical and psychological health, as well as their level of independence. The objective of our study was to evaluate the QoL of patients suffering from chronic low back pain (CLBP) and lumbosciatica (LS) and to identify associated factors.
Materials and Methods :
This was a descriptive cross-sectional study conducted at the Rheumatology Department of the Taher Sfar University Hospital in Mahdia. The study included 152 patients consulting for common CLBP or LS.
Pain Intensity: Measured using the Visual Analogue Scale (VAS).
Quality of Life: Assessed using the SF-36 (Short Form-36 Health Survey).
Functional Impact: Evaluated using the Quebec Back Pain Disability Scale.
Mood Disorders: Assessed using the Hospital Anxiety and Depression (HAD) Scale.
Results :
The mean age of the patients was 53.7 ± 11.3 years (range: 23–79), with a female predominance (61.2%). The mean pain VAS score was 46.5 ± 50 mm (range: 1–9), and the mean disease duration was 6.4 ± 5.1 years (range: 5 months – 24 years).
The overall mean SF-36 Scores was 41.3 ± 16.4 : The Physical Component Summary (PCS) was 35.5 ± 19.7 and The Mental Component Summary (MCS) was 47.1 ± 17.8.
An impaired quality of life (OMS < 66.7) was noted in 90.8% of patients.
Regarding Functional & Mood Scores, The mean Quebec score was 45.2 ± 19.5. The mean depression score was 8.7 ± 2.9 and the mean anxiety score was 9.3 ± 4.8.
Statistical analysis revealed a significant association between impaired QoL and Depression (p = 0.015), Anxiety (p = 0.002), and Functional disability (Quebec score) (p = 0.012)
There was no significant association between QoL and age, sex, obesity, pain VAS, or the duration of the disease.
Conclusion :
Chronic low back pain and lumbosciatica, which cause significant functional and socio-professional disability, can severely diminish the quality of life of those affected.

P161

EPIDEMIOLOGICAL PROFILE OF ANKLE TRAUMA IN PHYSICAL MEDICINE AND REHABILITATION: A STUDY OF 73 CASES

A. Fekih[1], I. Haddada[2], J. Saadana[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
The ankle is a vulnerable joint that is frequently subject to trauma. While the clinical course is often favorable, complications can arise in the short or long term, potentially compromising ankle function. Our primary objectives were to study the epidemiological and clinical characteristics of ankle trauma in a rehabilitation setting and to identify potential complications and their associated factors.
Materials and Methods :
We conducted a descriptive and analytical retrospective study of the records of 73 patients treated at the Physical Medicine and Functional Rehabilitation Department of the Taher Sfar University Hospital in Mahdia. The study focused on ankle trauma over a three-year period.
Results :
The mean age of the population was 41.5 ± 14.8 years, with a sex ratio (M/F) of 0.58.
The most frequent cause of trauma was a fall (41.1%), followed by domestic accidents (26%).
Ligamentous injuries were present in 60.3% of cases, followed by bone lesions (fractures) in 38.3%, and joint dislocation in 1.4%.
Late-stage complications were noted in 68.4% of patients, including: Complex Regional Pain Syndrome (CRPS/Algodystrophy): 34.2%, Joint Stiffness: 26%, and Ankle Osteoarthritis: 8.2%
Statistical analysis revealed a significant association between the occurrence of late complications and Age (p = 0.001), Type of lesion (p < 0.001), Surgical treatment (p = 0.001), and Number of functional rehabilitation sessions (p = 0.006).
Conclusion :
This study provides a foundation for future research with larger populations to better investigate these complications. Identifying these risk factors is essential to optimizing management and improving long-term outcomes for patients with ankle trauma.

P162

MOOD DISORDERS IN ELDERLY PATIENTS WITH CHRONIC LOW BACK PAIN

A. Fekih[1], I. Haddada[2], J. Saadana[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], I. Aloui[1], A. Abid[1]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Chronic low back pain (CLBP) is a frequently reported symptom among the elderly and has the potential to threaten their functional independence.

Depression is often a recurrent condition, triggered and exacerbated by both psychological stress and medical illnesses. The objective of this study was to measure the impact of chronic low back pain on psycho-behavioral factors within the geriatric population.

Materials and Methods :

This was a cross-sectional study involving 72 patients over the age of 65 suffering from chronic low back pain, conducted over a seven-month period . We investigated the relationship between CLBP and mood disorders (anxiety and depression) using the Hospital Anxiety and Depression (HAD) scale.

Results :

The mean age of the patients was 68.50 years (range: 65–79 years), with women representing 52.8% of the cohort.

Pain was mechanical in 97.2% of patients and inflammatory in 2.8%. The mean pain VAS score was 4.13 (range: 1–9).

Treatment Modalities: 52.8% of cases were on analgesics, 77.8% on NSAIDs, 25% received local corticosteroid injections, 33.3% underwent physical therapy, and 5.6% had surgical treatment.

Mood Assessment (HAD Scale): Depression: Scores ranged from 4 to 13 with a mean of 8.36. Notably, 44.4% of the population showed no depressive symptoms (score ≤ 7). The mean anxiety score was 7.22 (range: 1–15). Results showed that 58.3% had no anxiety, 19.4% had doubtful anxiety (score 8–10), and 22.2% had definite anxiety (score > 10).

Conclusion :

Due to the increased prevalence of mood disorders among elderly patients with low back pain, systematic screening for both depression and anxiety in this population is essential. Such screening allows for the implementation of well-targeted, multidisciplinary management plans.

P163

SIMULTANEOUS DOUBLE FEMORAL AND TIBIAL OSTEOTOMY IN THE TREATMENT OF SEVERE GENU VARUM IN YOUNG ADULTS

A. Fekih[1], J. Saadana[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

Severe constitutional knee deformities in young adults, particularly varus malalignment, present significant challenges in planning and therapeutic management. The primary goal of treatment is to delay the onset of knee osteoarthritis as much as possible by restoring a near-normal mechanical axis. One surgical alternative is the simultaneous double osteotomy of the femur and tibia in a single operative session.

Case report:

We report the case of a 30-year-old male with dwarfism secondary to multiple epiphyseal dysplasia, who presented with bilateral knee pain and severe genu varum. Clinical examination revealed preserved mobility in both knees with an intercondylar distance of 25 cm. Radiological assessment showed preserved joint spaces with an HKA angle of 149° on the right and 145° on the left. Given the significant functional impairment, a conservative surgical approach was chosen: a simultaneous distal femoral and proximal tibial osteotomy.

The first step involved a lateral closing-wedge femoral valgus osteotomy, stabilized by a DCS plate. The second step consisted of a medial opening-wedge tibial valgus osteotomy, stabilized by a T-plate, with the bone wedge from the femoral osteotomy used as an autograft.

Postoperative recovery was uneventful. Partial weight-bearing was delayed until the 45th day, accompanied by rehabilitation and muscle strengthening. Full weight-bearing was permitted at 3 months following radiological confirmation of consolidation at both osteotomy sites.

The contralateral side was operated on using the same technique one year later, with favorable clinical and radiological outcomes.

At the one-year follow-up, the patient reported high satisfaction with the functional outcome of both knees, despite a slight residual varus noted on weight-bearing long-leg radiographs.

Discussion:

Combined distal femoral and proximal tibial osteotomy for severe genu varum is a complex procedure that is infrequently described in the literature. The advantage of performing both osteotomies in a single procedure is the reduction in the number of anesthesia sessions and the acceleration of the overall rehabilitation protocol.

Conclusion:

Simultaneous double femoral and tibial osteotomy appears to be a highly effective option for severe genu varum, provided it is well-mastered. When assisted by computer navigation, the procedure becomes more reliable, precise, and reproducible.

P164

BILATERAL FEMORAL NECK FRACTURES ON PATHOLOGICAL BONE IN YOUNG ADULTS: A REPORT OF TWO CASES

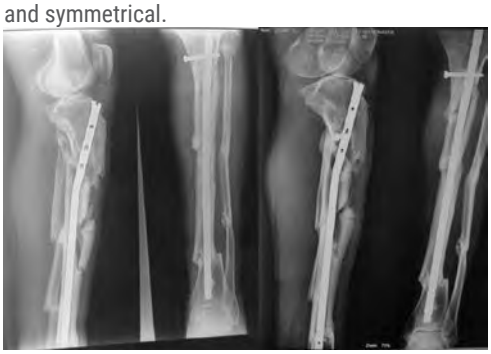
A. Fekih[1], J. Saadana[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

Simultaneous bilateral femoral neck fractures are extremely rare and typically occur following high-energy trauma or seizures. In young adults, the occurrence of such injuries after minor trauma should raise suspicion of underlying bone fragility. We report two cases of bilateral femoral neck fractures associated with phosphorus-calcium metabolic disorders.

Case report:
Two patients (aged 36 and 40) presented with bilateral femoral neck fractures following a simple slip (low-energy trauma). Case 1 is a 36-year-old patient being treated for distal tubular acidosis. Case 2 is a 40-year-old patient with end-stage chronic renal failure on hemodialysis. Clinical examination revealed total functional impairment of both lower limbs. Radiological assessment confirmed, in both cases, displaced true bilateral intracapsular cervical fractures in coxa vara.
Both patients underwent emergency surgery. Reduction on an orthopedic table followed by bilateral internal fixation using a DHS (Dynamic Hip Screw) was performed in a single operative session. In postoperative care, weight-bearing was delayed until radiological signs of consolidation appeared. Consolidation was achieved in both patients.
At the two-year follow-up, the patients demonstrated complete pain-free walking autonomy. Imaging showed no signs of avascular necrosis (AVN) of the femoral head or non-union.



Discussion:
Bilateral femoral neck fractures resulting from minor trauma are pathognomonic of bone-weakening diseases. Chronic renal failure and distal tubular acidosis induce major disturbances in mineral metabolism (renal osteodystrophy, osteomalacia), compromising the mechanical strength of the femoral neck.
The therapeutic challenge lies in early fixation to limit the risk of necrosis—which is particularly high in young patients—and in managing the underlying metabolic pathology to promote healing. The choice of the DHS plate provides the necessary stability to counteract the significant shearing forces at the femoral neck.
Conclusion:
Bilateral femoral neck fractures in young adults after minimal trauma necessitate a comprehensive metabolic workup. Early, stable internal fixation combined with the correction of calcium-phosphorus imbalances leads to excellent functional outcomes and prevents serious complications such as cephalic necrosis.

P165
TRI-FOCAL LEG FRACTURE: A CASE STUDY MANAGED BY INTRAMEDULLARY NAILING

A. Fekih[1], J. Saadana[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:
Tri-focal (or triple-level) tibial fractures are rare injuries, typically resulting from high-energy kinetic trauma. They present a major therapeutic challenge due to the complexity of reduction and the high risk of vascular complications or non-union, particularly within the intermediate bone segments. We report a case of a tri-focal leg fracture in an adult successfully treated with internal fixation.
Case report:
A 50-year-old male with no significant medical history was admitted following a road traffic accident (direct impact by a car). Radiological assessment revealed a closed tri-focal fracture of the right leg, involving three distinct fracture sites along the tibial shaft. The patient underwent emergency surgery. The therapeutic strategy consisted of closed-reduction intramedullary nailing (IMN) of the tibia under fluoroscopic guidance, with proximal and distal interlocking.
Satisfactory reduction was achieved for all three fracture sites using a closed approach. Weight-bearing was initially restricted, followed by protected partial weight-bearing starting at the 6th week. Clinical and radiological consolidation was achieved synchronously across all three fracture sites by the 5-month mark. No complications such as infection, malunion, or compartment syndrome occurred.
At the one-year follow-up, the patient demonstrated a normal gait without technical aids or pain. Knee and ankle range of motion were fully preserved and symmetrical.

Discussion:
The treatment of multi-focal tibial fractures remains a subject of debate (external fixation vs. nailing). However, closed intramedullary nailing is widely considered the "gold standard" as it preserves the periosteal blood supply and the fracture hematoma - crucial factors for the consolidation of intermediate segments that are often devascularized. The main difficulty lies in maintaining rotational and axial alignment across multiple levels simultaneously.
Conclusion:
Tri-focal leg fractures are rare clinical entities. Closed intramedullary nailing provides sufficient stability for reliable consolidation of all fracture sites while minimizing the risk of skin complications and infection.

P166

CHRONIC CALCIFYING HOFFA'S DISEASE: A CASE REPORT IN A 75-YEAR-OLD PATIENT

A. Fekih[1], J. Saadana[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:
Hoffa's disease, or infrapatellar fat pad impingement syndrome, results from chronic entrapment of the adipose tissue between the femur and the patella. While inflammation and fibrosis are common features, progression to calcification or ossification (ossifying Hoffitis) is rare and can mimic neighboring soft tissue tumors. We report a case of symptomatic calcified Hoffa's disease in a 75-year-old patient.
Case report:
A 75-year-old female patient presented with a two-year history of disabling anterior right knee pain, without recent trauma. Physical examination revealed a firm subpatellar mass and limited range of motion. MRI Imaging revealed a mass within the Hoffa fat pad, characterized by a marked low signal (hypointense) on both T1 and T2-weighted sequences, with no central enhancement, indicating significant calcification. The mass measured 3 cm in its largest dimension and exerted a mass effect on the patellar tendon.

Surgery consisted in a resection of a whitish, stony-hard mass embedded within remodeled fatty tissue.
Histological examination confirmed the diagnosis of Hoffa's disease at the stage of extensive fibrosis associated with calcified remodeling and areas of fibrocartilaginous metaplasia (extra-synovial osteochondroma). Postoperative recovery was uneventful, with the resolution of joint locking and a return to painless walking at the 3-month follow-up.
Discussion:
Chronic Hoffa's disease typically progresses through three stages: inflammation, fibrosis, and finally calcification or ossification. In elderly patients, this terminal stage can pose a diagnostic challenge, often requiring differentiation from para-articular osteochondromas or soft tissue chondromas. MRI is the gold standard for diagnosis, demonstrating the characteristic signal void of calcification within the infrapatellar fat. Total surgical resection is the treatment of choice at this stage, offering an excellent functional prognosis.
Conclusion:
Although rare in its calcified stage, Hoffa's disease should be included in the differential diagnosis of anterior knee masses in the elderly. Radio-pathological correlation is essential to confirm the benign nature of the lesion and to validate the success of surgical intervention.

P167

GIANT LIPOMA OF THE SHOULDER: A CASE REPORT OF AN UNUSUAL 30-CM TUMOR

A. Fekih[1], J. Saadana[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:
Lipomas are the most common benign mesenchymal soft tissue tumors. They are classified as "giant" when they exceed 10 cm in their largest dimension or weigh more than 1000 g.
Case report:
A 40-year-old female patient presented with a voluminous swelling on her right shoulder that had been progressively evolving for over 10 years. The primary complaints were aesthetic concerns and functional discomfort (difficulty with clothing and lying in a supine position). Clinical examination revealed a soft, non-tender, mobile mass measuring approximately 30 cm along its long axis.
MRI Imaging revealed a massive lesion occupying the entire posterior scapular region, showing a signal intensity identical to subcutaneous fat (hyperintense on T1 and T2-weighted sequences, with a complete signal drop on fat-saturation sequences). The mass was well-circumscribed, with no evidence of invasion into adjacent muscle structures or suspicious thickened septa.
A complete surgical excision was performed via a direct approach. The operative specimen confirmed an encapsulated fatty mass measuring 30 x 18 x 10 cm.
Histological examination concluded a benign mature lipoma, with no cellular atypia or signs of malignancy (liposarcoma).
Postoperative recovery was uneventful. At the 6-month follow-up, the patient showed excellent healing, full recovery of shoulder mobility, and high aesthetic satisfaction.

Discussion:
Giant lipomas of the shoulder are rare and can pose a diagnostic challenge in differentiating them from well-differentiated liposarcomas. MRI is the modality of choice to confirm the lipomatous nature and screen for signs of malignancy (size > 10 cm, septa thicker than 2 mm, or nodular areas). Despite the impressive 30-cm size in this case, the encapsulated appearance and lack of enhancement pointed toward benignity. Surgical treatment remains the standard of care, relieving mechanical constraints and improving the patient's quality of life.
Conclusion:
Giant lipomas, though benign, can reach spectacular dimensions when allowed to evolve over several decades. MRI is indispensable for preoperative assessment. Careful surgical resection ensures a complete cure with a near-zero risk of recurrence, provided the excision is total.

P168

SURGICAL MANAGEMENT OF CONGENITAL MACRODACTYLY OF THE SECOND TOE: A CASE REPORT

A. Fekih[1], J. Saadana[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Congenital macrodactyly is a rare, non-hereditary malformation characterized by the hamartomatous overgrowth of all mesenchymal elements (bone, fat, skin, and nerves) of one or more digits. In the foot, this condition leads to significant cosmetic deformity, footwear difficulties, and gait disturbances.
Case report :
We report the case of a 6-year-old boy presenting with isolated, progressive hypertrophy of the second left toe since birth.
In clinical presentation, there is a massive enlargement of the ray causing a mechanical obstacle to normal footwear and an aesthetic complex.
X-rays revealed marked longitudinal and diametric overgrowth of the phalanges and the corresponding metatarsal.
Due to the severity of the overgrowth and the limited potential for conservative remodeling, a ray resection (amputation) was performed. This was combined with a first web space plastoplasty to close the gap, reconstruct the interdigital space, and ensure a harmonious forefoot contour. Postoperatively, healing was uneventful with no skin necrosis or infection. At the latest follow-up, the functional outcome was excellent.
The patient demonstrated a normal gait pattern and was able to wear standard commercial shoes without discomfort. The parents reported high satisfaction with the cosmetic appearance of the foot.

Discussion :
The management of macrodactyly is challenging due to its progressive nature. While conservative procedures (such as debulking or epiphysiodesis) may be attempted in mild cases, radical ray resection remains the gold standard for severe, disproportionate macrodactyly. It provides a definitive solution to footwear issues. The inclusion of a web space plastoplasty is crucial to prevent "V-shaped" foot deformities and to achieve a natural-looking forefoot width.
Conclusion :
Macrodactyly of the second toe is a disabling condition. In severe forms, surgical resection combined with commissural reconstruction is an effective and reliable treatment. It provides a stable functional result and a satisfactory aesthetic outcome, allowing the child to reintegrate into normal physical and social activities.

P169

TOTAL KNEE ARTHROPLASTY FOR GENU VALGUM: A RETROSPECTIVE ANALYSIS OF FUNCTIONAL AND RADIOLOGICAL OUTCOMES IN 40 CASES

A. Fekih[1], J. Saadana[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:
Genu valgum presents a specific surgical challenge during Total Knee Arthroplasty (TKA) due to associated bone remodeling, lateral soft-tissue contractures, and complex ligamentous imbalance. This study aimed to evaluate the functional and radiological outcomes of TKA in patients with genu valgum, identify factors influencing postoperative

performance, and propose practical recommendations based on our clinical experience.

Materials and Methods:

We conducted a retrospective study of 40 TKAs implanted for genu valgum deformity. Functional assessment was performed using the Knee Society Score (IKS) (Knee and Function sub-scores). Radiological analysis included the measurement of the Hip-Knee-Ankle (HKA) angle pre- and postoperatively, as well as patellar tracking evaluation. Intraoperative parameters analyzed included the surgical approach, lateral release techniques, bone cut management, residual laxity, and patellar resurfacing. Statistical significance was set at $p < 0.05$.

Results:

Successful correction of the mechanical axis was achieved in 35 cases (87.5%). Failure to achieve neutral alignment was significantly associated with severe valgus (HKA > 200°, $p = 0.022$) and tibial cut technical errors. Functional improvement was significant, with a substantial increase in the postoperative IKS score. Residual medial laxity was the strongest predictor of a lower IKS score ($p = 0.005$).

Patellar resurfacing, although performed selectively, significantly improved postoperative flexion ($p = 0.009$). Additionally, a rehabilitation duration of 3 months was associated with superior functional outcomes ($p = 0.023$). Postoperative patellar tracking was satisfactory in most cases, regardless of whether resurfacing was performed.

Conclusion:

TKA for genu valgum yields excellent results provided the surgical strategy is tailored to the severity of the deformity. This includes rigorous control of tibial cuts, precise ligamentous balancing to eliminate medial laxity, and the use of a lateral approach for severe cases. Selective patellar resurfacing and early rehabilitation further optimize functional recovery.

The findings of this study have led to the development of a decision-making algorithm to improve the reproducibility and performance of TKA in the valgus knee.

P170

FUNCTIONAL OUTCOMES AND HEALTH-RELATED QUALITY OF LIFE FOLLOWING TOTAL KNEE ARTHROPLASTY

A. Fekih[1], J. Saadana[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

Knee osteoarthritis (KOA) is a leading cause of disability worldwide, with a rising incidence linked to aging and obesity. When conservative management fails in advanced stages, Total Knee Arthroplasty (TKA) serves as the definitive surgical solution. This study aims to evaluate the functional recovery, psychological impact, and overall quality of life (QoL) in patients following TKA.

Materials and Methods:

We conducted a retrospective, analytical study of patients undergoing TKA between January and December 2022. Multiple validated instruments were utilized for assessment: the New Knee Society Score (New IKS) and the Knee Injury and Osteoarthritis Outcome Score (KOOS) for joint-specific function; the Short Form-36 (SF-36) for general QoL; the Pittsburgh Sleep Quality Index (PSQI) for sleep hygiene; and the Hospital Anxiety and Depression Scale (HADS) for psychological screening.

Results:

The cohort (mean age 64.9 years, predominantly female) presented with severe baseline morbidity: 70% had varus deformities, and 80% had a limited walking perimeter (< 500m).

Significant improvements were observed in the mean KOOS (73.2 post-op vs. 33.3 pre-op) and New IKS scores (improving to a mean of 80 post-op). The SF-36 scores demonstrated statistically significant gains, particularly in the Physical Component Summary (PCS).

Sleep quality improved dramatically ($p < 0.001$), with the prevalence of "good sleepers" rising from 14% to 86%. Furthermore, "definite anxiety" and "definite depression" rates fell from 25% to 8% and 15% to 7%, respectively.

Univariate analysis confirmed that functional and QoL improvements were independent of age, sex, or BMI.

Discussion:

The significant reduction in anxiety and depression scores post-TKA suggests that joint replacement surgery provides benefits far beyond mechanical stability; it restores psychological equilibrium by resolving chronic pain and social isolation. The restoration of sleep (PSQI) appears to be a major mediator in the improvement of the SF-36 mental component. However, despite high satisfaction rates, a gap remains between clinical success and patient expectations, highlighting the need for thorough preoperative counseling.

Conclusion:

TKA provides substantial multi-dimensional benefits, significantly improving disease-specific function, sleep quality, and psychological health.

In our hospital setting, these results validate TKA as a highly effective intervention for advanced knee osteoarthritis, regardless of patient demographics.

P171

SHORT- AND MEDIUM-TERM CLINICAL AND RADIOLOGICAL OUTCOMES OF BIPOLAR HEMIARTHROPLASTY FOR FEMORAL NECK FRACTURES

A. Fekih[1], J. Saadana[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :

Bipolar hemiarthroplasty (BH) has significantly advanced the management of displaced femoral neck fractures in the elderly. These implants were designed to minimize acetabular wear and erosion, a common complication associated with unipolar prostheses (Austin-Moore or Thompson). This study aims to evaluate the clinical and radiological outcomes, as well as the quality of life, in patients treated with BH in the short and medium term.

Materials and Methods :

We conducted a retrospective study of 100 bipolar hemiarthroplasties performed for femoral neck fractures. Patients were evaluated clinically using the Postel-Merle d'Aubigné (PMA) score, radiologically through standard follow-up imaging, and for quality of life using the SF-36 Health Survey (Physical Component Summary - PCS and Mental Component

Summary - MCS).

Results :

The postoperative complication rate included one case of early-onset infection and two cases of early posterior dislocation. At a mean follow-up of 31.2 months, 77.2% of patients achieved satisfactory results according to the PMA score.

The mean SF-36 PCS (Physical) was 33.8, and the mean SF-36 MCS (Mental) was 44.6.

The majority of patients showed stable implant positioning with no significant acetabular erosion during the study period.

Discussion :

Our findings suggest that BH is a reliable procedure, particularly regarding pain relief and the restoration of walking ability. These functional gains correlate well with radiological stability. The "buffer effect" provided by the polyethylene interface appears to protect the acetabular cartilage, delaying the onset of asymptomatic wear.

While literature suggests that BH offers superior clinical and radiological outcomes compared to unipolar prostheses, it comes at a higher financial cost. Furthermore, a selection bias was noted in our series: BH was primarily accessible to patients with adequate social security coverage, reflecting a higher socioeconomic status which may independently influence quality of life scores.

Conclusion :

Based on these short- and medium-term outcomes, bipolar hemiarthroplasty remains the treatment of choice for displaced femoral neck fractures in elderly patients without pre-existing osteoarthritis. It provides a balanced compromise between surgical simplicity and the preservation of the acetabulum.

P172

OUTCOMES OF THE LATARJET PROCEDURE FOR RECURRENT ANTERIOR SHOULDER INSTABILITY IN COMPETITIVE HANDBALL PLAYERS: A LONG-TERM FOLLOW-UP STUDY

A. Fekih[1], J. Saadana[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

Recurrent anterior shoulder instability poses a significant therapeutic challenge in high-demand overhead and contact athletes, such as handball players. The Latarjet procedure is often preferred for its "triple-lock" effect.

Materials and Methods:

We conducted a retrospective study of 16 male competitive handball players (mean age: 27 years) who underwent the Latarjet procedure for chronic anterior instability. Clinical assessment focused on the dominant shoulder, which was involved in the majority of cases. Preoperative evaluation revealed glenoid or humeral bone loss (Hill-Sachs lesions) in 80% of the cohort. Functional outcomes were measured using the Walch-Duplay and the Western Ontario Shoulder Instability (WOSI) scores at a mean follow-up of 15months.

Results:

The primary mechanism of initial injury was a traumatic sporting collision in all cases. Postoperatively, 43.75% of patients returned to their pre-injury level of competition within an average of nine months. One patient (6.25%) experienced a recurrence of instability following a new high-energy trauma. At the final follow-up, the mean Walch-Duplay score was 82.7, with 68.75% of patients achieving "Excellent" or "Good" results. The mean WOSI score was 57.04/2100. While 87.5% of patients reported high satisfaction, three patients (18.75%) described persistent functional discomfort during overhead sports activities, specifically during the late cocking phase of throwing.

Discussion:

The Latarjet procedure demonstrates excellent stability and high patient satisfaction rates in the long term. However, the return-to-play rate at the same competitive level remains a critical point of discussion. The discrepancy between clinical stability and subjective sporting comfort in handball players suggests that while the bone block effectively prevents recurrence, subtle deficits in proprioception or range of motion (internal rotation) may impact high-level throwing performance. Bone loss remains a primary indication, justifying the choice of this technique over soft-tissue repair in this population.

Conclusion:

The Latarjet procedure is a reliable and robust technique for treating recurrent shoulder dislocation in handball players. It provides excellent long-term joint stability; however, athletes should be counseled that returning to the elite level of competition may be influenced by residual functional discomfort during high-velocity throwing.

P173

FUNCTIONAL OUTCOMES OF SURGICAL MANAGEMENT FOR MASON TYPE IV RADIAL HEAD FRACTURES IN ATHLETES: A THREE-CASE SERIES

A. Fekih[1], J. Saadana[1], H. Ammar[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

Radial head fractures are common yet polymorphic, often presenting diagnostic and therapeutic challenges. When associated with elbow dislocation (Mason Type IV), these complex injuries threaten not only the stability and mobility of the elbow but also the distal function of the wrist and hand. This study aims to evaluate the clinical, radiological, and functional outcomes of various surgical methods used to treat Mason Type IV fractures in young, athletic patients.

Materials and Methods:

We report three cases of Mason Type IV radial head fractures (classified according to the Broberg and Morrey modification) resulting from sports-related accidents. Three distinct therapeutic strategies were employed: Radial head resection associated with external fixation, Open Reduction Internal Fixation (ORIF) using buried headless compression screws, and Prosthetic replacement with a pyrocarbon radial head prosthesis.

Evaluation at the final follow-up included clinical stability, range of motion, standard radiographic assessment, and the Mayo Elbow Performance Score (MEPS).

Results:

At the final follow-up, all patients demonstrated stable elbows with nearly full range of motion. Functional evaluation via MEPS yielded "Fair" to

"Good" results. However, only one patient successfully returned to their pre-injury level of athletic activity.

Discussion:

Based on these results and a literature review, a precise preoperative assessment is mandatory to identify bone and ligamentous injuries that compromise elbow stability. Systematic intraoperative testing in both sagittal and frontal planes is essential.

Resection, though historically common, should generally be abandoned in the presence of destabilizing lesions, as it increases the risk of proximal radial migration and valgus instability.

ORIF is the ideal indication for Type IVa fractures but carries risks of secondary necrosis, non-union, and stiffness.

Radial Head Arthroplasty (RHA) appears to be the superior option for Type IVb fractures. By restoring the lateral column, RHA can stabilize the elbow even in the presence of difficult-to-repair medial collateral ligament injuries.

Conclusion:

The management of Mason IV fractures in athletes is demanding. While ORIF is preferred when feasible, radial head prosthesis offers encouraging results by restoring stability through a rigorous surgical technique, ultimately facilitating functional recovery.

P174

LIMB-SALVAGE SURGERY FOR PRIMARY MALIGNANT BONE TUMORS OF THE PROXIMAL HUMERUS: A MULTI-CENTER STUDY

A. Fekih[1], J. Saadana[1], H. Ratib[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective:

The proximal humerus is the fourth most common site for primary malignant bone tumors. The primary goal of limb-salvage surgery is to achieve oncologically safe resection margins while preserving the maximum possible function of the upper limb.

Materials and Methods:

We conducted a retrospective, bicentric study over a 12-year period (2012–2024), involving 13 patients treated for primary malignant bone tumors of the proximal humerus. Resection margins were evaluated according to the Enneking/MSTS classification. Functional outcomes were assessed using the MSTS functional score, alongside radiological follow-up and complication analysis.

Results:

The mean age was 41.7 years, with a mean follow-up of 58.6 months. The cohort included 6 chondrosarcomas, 4 osteosarcomas, and 3 Ewing sarcomas. Resection types according to Malawer's classification included intra-articular (Type A): 6 cases (S4S5, S3S4S5, S3S4) and extra-articular (Type B): 7 cases (S3S4, S3S4S5).

Reconstruction methods were varied: 4 cement-augmented nails (spacer), 1 reverse Total Shoulder Arthroplasty (rTSA), 1 massive tumor prosthesis, 4 scapulohumeral arthrodeses, 1 segmental reconstruction with epiphyseal preservation, and 2 suspensionplasties (Symeonides procedure). The mean MSTS functional scores were: rTSA: 85%, Tumor prosthesis: 82%, Epiphyseal preservation: 80%, Cemented nail: 75%, Arthrodesis: 71%, and Suspensionplasty: 60%.

One patient died due to local recurrence. Complications included local recurrence, infection, and prosthetic instability.

Discussion:

Reconstructing the proximal humerus post-resection is a major surgical challenge. The success of conservative surgery relies on oncological safety while attempting to preserve the axillary nerve and the deltoid muscle. This requires meticulous preoperative planning (MRI, PET-CT) and intraoperative frozen section analysis. While prosthetic reconstructions (rTSA and tumor prostheses) offer superior functional scores, they are associated with higher risks of instability and infection compared to biological reconstructions or arthrodesis. These complex procedures should ideally be performed in specialized oncological centers.

Conclusion:

Oncological clearance must remain the absolute priority over functional reconstruction. The final functional outcome depends heavily on the type of bone resection, but even more so on the preservation or reconstruction of the abductor apparatus (deltoid and rotator cuff). Early detection remains the most critical factor in improving both survival and functional prognosis.

P175

COMPLEX BIPOLAR FOREARM TRAUMA IN CHILDREN: MONTEGGIA INJURY ASSOCIATED WITH AN IPSILATERAL DISTAL FRACTURE

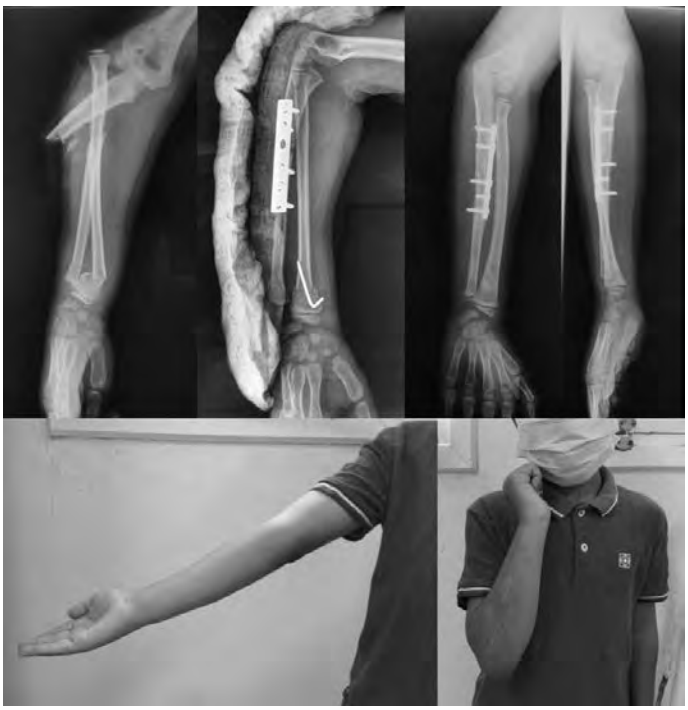
A. Fekih[1], J. Saadana[1], M. Frikha[1], Y. Guermazi[1], M. Khalil[1], I. Bouselmi[1], H. Ammar[1], H. Ratib[1], I. Aloui[1], A. Abid[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :

Monteggia fracture-dislocations are well-documented injuries in the pediatric population. However, their association with a fracture of the distal fourth of both forearm bones—referred to as a "bipolar" or "double-level" injury—is extremely rare. This configuration creates a "floating" intermediate bone segment, significantly increasing instability and therapeutic complexity.

Case report :



A 7-year-old child was admitted following a sports accident with an open trauma (Gustilo-Anderson type I / Cauchoix 1) of the right forearm. Radiographic evaluation revealed a complex injury pattern: A diaphyseal fracture of the ulna associated with an anterior dislocation of the radial head (Bado Type I Monteggia lesion) and a minimally displaced fracture of the distal fourth of the ipsilateral radius and ulna.

The patient underwent emergency surgery for stabilization of both injury sites.

Following wound debridement, an open reduction of the ulna was performed and stabilized with a compression plate. This maneuver resulted in the spontaneous and stable reduction of the radial head. The distal radial fracture was stabilized using percutaneous styloid pinning (K-wiring).

Bone healing was achieved within 6 weeks. The hardware was removed after 18 months.

At the 2-year final follow-up, the functional result was excellent, with a full range of motion in the elbow (flexion-extension and prono-supination) and wrist. No growth complications or physeal issues were observed.

Discussion :
The primary challenge in bipolar fractures is restoring the length and alignment of the ulna, which is an absolute prerequisite for maintaining the reduction of the radial head. While intramedullary nailing is often preferred in children, the use of a compression plate in this specific case provided the rigid stability necessary to manage a multi-level unstable forearm. Distal radial pinning completed the stabilization of the forearm frame, preventing secondary displacement.
Conclusion :
The association of a Monteggia lesion with a distal forearm fracture is a surgical emergency. Stable osteosynthesis, combining plate fixation and pinning, prevents classic complications such as non-union or chronic radial head dislocation, ensuring a full long-term functional recovery.

P176
ULNAR NERVE COMPRESSION BY POST-TRAUMATIC HETEROTOPIC OSSIFICATION: A CASE REPORT

A. Fekih[1], J. Saadana[1], H. Ratib[1], I. Bouselmi[1], M. Frikha[1], M. Khalil[1], Y. Guermazi[1], I. Aloui[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Neurogenic heterotopic ossification, also known as para-osteoarthropathy, is a frequent complication following severe traumatic brain injury. While these ossifications typically impair joint mobility, their development can also lead to complex peripheral nerve compressions. We report a case of ulnar nerve compression at the elbow, where the nerve was completely encased by an osteoma in a brain-injured patient.
Case report :
A 30-year-old male with a history of severe traumatic brain injury (requiring a 25-day stay in intensive care) presented with progressive symptoms of right ulnar neuropathy. He reported paresthesias in the fourth and fifth digits, associated with elbow stiffness. Clinical examination revealed a hard, bone-like mass on the medial aspect of the right elbow.
Computed Tomography revealed a massive osteogenic formation in the epitrochlear (medial epicondyle) region. The imaging characteristically showed circumferential encasement of the ulnar nerve, with the osteoma literally surrounding the nerve within its groove.
Electromyography confirmed severe ulnar neuropathy at the elbow with a major conduction block.
The patient underwent surgery for complete resection of the osteoma. Intraoperatively, the nerve was meticulously liberated from its "bony straitjacket."
Postoperative outcomes included a complete restoration of elbow range of motion, a progressive resolution of preoperative paresthesias, and a satisfactory short-term sensory recovery.
Discussion
This case illustrates the unique pathogenesis of neurogenic heterotopic ossification, where newly formed bone does not merely displace adjacent structures but can literally incorporate them. The topography of the epitrochlear-olecranon groove (cubital tunnel) is critical due to the limited anatomical space.
This observation highlights the necessity of cautious neurolysis. Unlike classic tunnel syndromes, the rapid resolution of symptoms following resection confirms that the compression here is purely mechanical and extrinsic. The neurological prognosis remains favorable provided the intervention is timely.
Conclusion
Ulnar nerve compression by neurogenic heterotopic ossification is a rare etiology that should be considered in any brain-injured patient presenting with sensory-motor deficits in the upper limb. Surgical resection provides a dual benefit: restoring joint function and achieving effective nerve decompression.

P177
TUBERCULOUS OSTEOMYELITIS OF THE HUMERAL HEAD SECONDARY TO BCG VACCINATION

A. Fekih[1], M. Frikha[1], M. Khalil[1], J. Saadana[1], Y. Guermazi[1], I. Bouselmi[1], H. Ratib[1], I. Aloui[1], I. Haddada[2]

[1]Orthopedic Department, Fattouma Bourguiba University Hospital, Monastir, Tunisia; [2]Physical Medecine Department, Taher Sfar University Hospital, Mahdia, Tunisia

Objective :
Given the endemic risk of tuberculosis in our country, BCG (Bacillus Calmette-Guérin) vaccination is mandatory at birth. Various cases of osteomyelitis secondary to the BCG vaccine have been reported in the literature. We report a case of tuberculous osteomyelitis of the humeral head following BCG vaccination in an 11-month-old infant.
Case Report :
An 11-month-old infant presented with right shoulder pain lasting for one month, accompanied by a fever. The patient was born at full term with normal psychomotor development, and his vaccination schedule was up to date.
Physical examination revealed severely painful range of motion in the right shoulder and the presence of right axillary lymphadenopathy, with no local inflammatory signs. Standard shoulder X-rays showed a poorly defined epiphyseo-diaphyseal osteolytic lesion of the proximal humerus with cortical breakthrough.

An MRI confirmed the expansive nature of the osteolytic process, showing extension into the joint space and surrounding soft tissues. Based on these findings, a surgical biopsy was performed; the histological results were consistent with bone tuberculosis. The patient was started on an antitubercular regimen (Isoniazid, Rifampin, and Ethambutol) with outpatient radiological follow-up.

At the 9-month follow-up, the patient is doing well with a normal growth curve. Radiologically, the lesion shows significant improvement and is currently healing.

Discussion :

The *Mycobacterium bovis* BCG strain used for vaccination was developed in 1921 by the Pasteur Institute from an attenuated bovine strain. According to the World Health Organization (WHO), approximately 100 million newborns are vaccinated with BCG worldwide each year.

The prevalence of osteomyelitis secondary to BCG vaccination is rare, estimated to occur in between 1 in 3333 and 1 in 100000000 vaccinations. The development of a BCG infection following vaccination may often be explained by the presence of a previously undiagnosed immunodeficiency.

Conclusion

BCG-induced osteomyelitis is a rare but potentially serious complication of vaccination. Prompt clinical suspicion, coordinated diagnostic investigations, and the early initiation of appropriate antibiotic therapy generally lead to a favorable prognosis.

P178

TRANSCRANIAL MAGNETIC STIMULATION IN THE REHABILITATION OF PATIENTS WITH MULTIPLE SCLEROSIS

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

In the context of multiple sclerosis (MS), a disease characterized not only by structural damage to myelin and axons but also by maladaptive plasticity of neural networks, TMS offers unique opportunities for non-invasive neuromodulation. The fundamental premise for this method is the concept of synaptopathy, according to which an inflammatory environment in the central nervous system disrupts synaptic transmission mechanisms (glutamatergic and GABAergic) long before neuronal death. Rhythmic TMS allows us to interfere with these processes, inducing phenomena similar to long-term potentiation (LTP) or long-term depression (LTD), thereby restoring functional connectivity in the brain and compensating for neurological deficits. The method is based on Faraday's law of electromagnetic induction.

A powerful, short-duration current pulse flowing through a coil generates a high-intensity alternating magnetic field (up to 2-3 Tesla), which easily penetrates the skin, aponeurosis, and cranial bones. In the conductive tissues of the brain, this field induces a secondary electric field, the vector of which is directed perpendicular to the magnetic flux. When the induced current reaches a threshold, depolarization of the membranes of cortical neurons occurs, primarily in the region of the axonal colliculi or the axonal curvatures of interneurons. However, the therapeutic effect of rTMS is due not so much to the depolarization itself as to post-stimulation changes in cortical excitability that persist after the session. Neurophysiological effects are strictly dependent on the stimulation frequency. Low-frequency stimulation (≤ 1 Hz) traditionally has an inhibitory effect, reducing the excitability of cortical areas through mechanisms similar to long-term depression (LTD) of synaptic transmission. In contrast, high-frequency stimulation (≥ 5 Hz) increases cortical excitability, mimicking long-term potentiation (LTP). Of particular interest are modern Theta Burst Stimulation (TBS) protocols, which achieve a powerful modulatory effect in a significantly shorter time (3–5 minutes) compared to classical protocols. The mechanisms of these plastic changes are associated with the activation of NMDA receptors, changes in intracellular calcium concentrations, and the expression of neurotrophic factors, particularly BDNF (brain-derived neurotrophic factor), the level of which is often reduced in MS. It is the ability of rTMS to influence BDNF secretion and trigger axon sprouting that makes this method pathogenetically justified for neurorehabilitation. One of the most clinically significant and proven applications of rTMS in MS is the treatment of spasticity. The pathophysiology of spasticity in demyelinating diseases is associated not only with the disinhibition of spinal reflexes due to damage to the pyramidal tract but also with altered excitability of the primary motor cortex (M1). Studies using paired stimulation have shown that patients with spasticity have impaired intracortical inhibition (SICI) mechanisms mediated by GABA-A receptors. The therapeutic strategy in this case is aimed at restoring corticospinal control.

P179

TRANSCRANIAL ELECTRICAL STIMULATION IN THE REHABILITATION OF PATIENTS WITH MULTIPLE SCLEROSIS

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

The therapeutic value of tDCS in chronic diseases such as MS is due to its long-term effects ("offline effects"), which persist from minutes to weeks after the stimulation session. These phenomena are based on mechanisms of synaptic plasticity similar to long-term potentiation (LTP) and long-term depression (LTD). The molecular cascade triggered by tDCS includes modulation of NMDA glutamate receptors, changes in intracellular calcium concentrations, and, most importantly, increased expression of brain-derived neurotrophic factor (BDNF). In multiple sclerosis, where inflammation suppresses neurotrophin production and impairs remyelination mechanisms, BDNF induction by tDCS may play a neuroprotective role. Furthermore, modern studies using resting-state fMRI demonstrate that tDCS can alter the global architecture of neural networks, strengthening functional connections between distant brain regions, which is critical for compensating for the "disconnection syndrome" characteristic of the demyelinating process. The effect on glial cells should also not be overlooked: microglia and astrocytes are also sensitive to electric fields, and modulating their activity can reduce local neuroinflammation.

Cognitive impairment, which affects up to 60–70% of MS patients, manifests primarily as decreased information processing speed, working memory, and attention deficits. The anatomical substrate of these functions is the dorsolateral prefrontal cortex (DLPFC), which serves as the primary target for tDCS in cognitive rehabilitation protocols. The standard electrode placement involves placing the anode on the left DLPFC (point F3 in the international 10-20 system) and the cathode on the contralateral brow ridge (Fp2) or right DLPFC (F4).

Clinical studies demonstrate that a course of anodal tDCS of the left DLPFC (10-20 sessions of 20 minutes, 1.5-2 mA) significantly improves performance on attention tests (PASAT) and the Symbol-Digit Test (SDMT). The mechanism of improvement is associated with increased

excitability of the prefrontal cortex, which facilitates the recruitment of neural resources for complex cognitive tasks. An important aspect is the synergy between tDCS and cognitive training: stimulation administered directly during task performance ("online") is more effective than stimulation at rest. This supports the concept of "activity-dependent plasticity": the electric field does not create new skills, but rather strengthens neural pathways that are voluntarily activated by the patient. Of particular interest is the finding that tDCS can reduce the phenomenon of "cognitive fatigue"—the depletion of mental resources during prolonged exercise, which is subjectively perceived by patients as a reduction in "brain fog."

P180

VIRTUAL REALITY TECHNOLOGIES IN COMPREHENSIVE REHABILITATION FOR MULTIPLE SCLEROSIS

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

In the modern neurorehabilitation paradigm, virtual reality (VR) technologies are viewed not simply as a way to add variety to routine physical therapy sessions, but as a complex neurophysiological tool that allows for the creation of so-called "enriched environments." For patients with multiple sclerosis (MS), whose daily activities are often limited by motor deficits, fatigue, and apathy, standard physical therapy methods may prove insufficient to stimulate adaptive changes in the central nervous system. VR technologies immerse patients in a computer-simulated world where interaction occurs in real time through multimodal sensory channels: visual, auditory, and tactile (haptic feedback).

A fundamental difference between VR therapy and traditional methods is the ability to manipulate feedback. In the physical world, a patient with paresis receives a signal of failure (failure to raise an arm, loss of balance), which reinforces the pathological pattern and the phenomenon of "learned disuse." In a virtual environment, we can programmatically enhance the avatar's range of motion, creating the illusion of success and activating the brain's reward system (dopaminergic pathways), which is critical for maintaining motivation and inducing neuroplasticity. Furthermore, VR enables the implementation of motor learning principles with high-intensity and task variability that cannot be replicated in a traditional gym, thereby ensuring training of not only motor but also cognitive functions within a single session.

The effectiveness of VR rehabilitation is based on several key neurobiological mechanisms, the most important of which is the activation of the mirror neuron system. Observing the actions of a virtual avatar performing limb movements from a first-person perspective activates the same neural networks in the premotor and parietal cortex as the actual movement. This phenomenon, known as “action observation,” when combined with ideomotor training, promotes the reorganization of motor maps in the cortex and the restoration of lost connections, even in cases of severe paresis.

P181

BIOFEEDBACK TECHNOLOGIES IN MULTIPLE SCLEROSIS NEUROREHABILITATION

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

Biofeedback (BFB) is a non-pharmacological therapeutic approach based on the fundamental principles of cybernetics and P.K. Anokhin's theory of functional systems. The method involves creating an external, artificial feedback circuit that allows the patient to receive real-time information about their physiological functions, which are usually unconscious or impaired due to a pathological process. In the context of multiple sclerosis (MS), where demyelination and axonal degeneration lead to the disruption of natural sensorimotor connections and distortion of proprioceptive information, BFB acts as a "sensory prosthesis." The technology transforms physiological signals (muscle electrical activity, brain rhythms, postural parameters, sphincter pressure) into perceptible visual or auditory images. This closes the broken reflex circuit and activates supraspinal control mechanisms, teaching the patient to voluntarily regulate impaired functions through operant conditioning and neuroplasticity.

The clinical effectiveness of biofeedback in multiple sclerosis relies on the central nervous system's ability to functionally reorganize even in the context of chronic neurodegenerative processes. The pathophysiological basis for functional recovery under the influence of biofeedback training is the phenomenon of "disinhibition" of functionally inactive but anatomically intact neural pathways, as well as the formation of new synaptic connections bypassing the damaged areas (vicariation). In MS, movement impairment is often associated not so much with complete paralysis as with disruption of afferent signal transmission: the brain sends a command to a muscle but does not receive a clear response, leading to incoordination and ataxia. Biofeedback compensates for this deficit through sensory substitution: proprioceptive information distorted by demyelination of the dorsal columns of the spinal cord is replaced by a high-precision visual signal on a monitor screen.

Regular training with biofeedback promotes the consolidation of motor skills. During the learning process, a transition occurs from energy-consuming, consciously controlled movement (involving the prefrontal cortex) to automated execution mediated by the basal ganglia and cerebellum. Importantly, biofeedback affects not only the effector component but also the psychoemotional state. Visualizing success (for example, successfully relaxing a spastic muscle, displayed on a graph) activates the limbic system and dopaminergic reward pathways, which reduces anxiety, increases motivation for rehabilitation, and creates an internal locus of control over the disease.

P182
FUNCTIONAL ELECTRICAL STIMULATION IN COMPREHENSIVE REHABILITATION FOR MULTIPLE SCLEROSIS

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

The method is based on the ability of short electrical pulses (usually rectangular, biphasic, and charge-compensated) to depolarize the axonal membrane of peripheral nerves. When correcting gait in patients with MS, the primary target is the common peroneal nerve (n. peroneus communis) in the region of the fibular head. Stimulation of this nerve causes contraction of the tibialis anterior and peroneal muscles (mm. peronei), enabling dorsiflexion and eversion of the foot. This is critical during the swing phase, preventing toe drag and the need for compensatory movements (circumduction, hip hyperextension, or "hip hiking").

Mechanism of action of FES is not limited to simple muscle contraction. Modern neuroimaging and electrophysiological data (TMS, fMRI) indicate a powerful afferent component of stimulation. The electrical impulse activates not only efferent motor fibers (alpha motor neurons) but also afferent sensory fibers (types Ia, Ib, and II). This massive flow of proprioceptive information reaches the spinal cord and then the sensorimotor cortex, closing reflex arcs and strengthening the cortical representation of the stimulated limb. In the literature, this phenomenon is described as the "therapeutic effect" of FES: regular use of the device leads to increased corticospinal excitability and a reorganization of neural networks according to the Hebbian principle ("neurons that fire together, wire together"). Clinically, this is manifested in the fact that after a course of FES, the patient begins to walk better even without the device turned on—a phenomenon unachievable with passive orthoses (AFOs). Furthermore, stimulation of the peroneal nerve causes reciprocal inhibition of antagonist muscles (the gastrocnemius and soleus muscles) through the activation of spinal interneurons. In patients with MS, who typically experience spasticity in the posterior calf muscles, this effect plays a key role in normalizing gait biomechanics, preventing equinus foot placement and reducing the risk of contractures.

P183
SMART REHABILITATION FOR MULTIPLE SCLEROSIS

A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

Types of Smart Technologies in MS Rehabilitation

Wearable Sensors and IoT Devices

Wearable sensors and Internet of Things (IoT) devices enable real-time symptom monitoring and gait analysis, critical for MS patients with mobility impairments. These devices capture motion, biometric data, and daily activity patterns, facilitating continuous disease monitoring in natural settings. For example, smart insoles and motion trackers provide objective data on gait characteristics and balance, which are essential for assessing disease progression and tailoring interventions. Cognitive monitoring is also advancing through AI-driven analysis of keystroke dynamics and neuropsychological test scoring, enabling unobtrusive assessment of cognitive impairment. This continuous monitoring supports early detection of symptom changes and personalized treatment adjustments.

Tele-Rehabilitation Platforms

Tele-rehabilitation platforms leverage internet communication technology to deliver physical and cognitive rehabilitation remotely, overcoming barriers of mobility, travel costs, and limited access to specialized care. These platforms provide virtual physical therapy sessions, remote monitoring, and patient education, improving accessibility and adherence. Tele-rehabilitation has demonstrated significant impacts on motor, cognitive, and participation parameters in MS patients, making it a vital tool especially in the context of the COVID-19 pandemic and beyond. By facilitating frequent and convenient access to care, tele-rehabilitation enhances patient engagement and continuity of treatment.

AI and Machine Learning Applications

AI and machine learning algorithms analyze large-scale patient data—including demographics, genetics, clinical presentations, and radiological findings—to improve diagnostic accuracy, tailor management plans, and predict disease progression. These technologies automate neuropsychological test scoring and analyze passive data streams from wearables, providing insights into cognitive and motor function. AI-driven virtual physiotherapy assistants (VPAs) offer real-time feedback and personalized support, enhancing adherence and reducing in-person visits. The integration of AI in smart rehabilitation represents a paradigm shift toward data-driven, adaptive care models that respond dynamically to patient needs.

Virtual and Augmented Reality (VR/AR)

VR and AR technologies provide immersive, multi-sensory environments for motor and cognitive rehabilitation. VR stimulates neuroplasticity through repetitive, task-oriented feedback, improving balance, movement, and cognitive function. Clinically validated VR programs for MS patients have shown improvements in motor skills and cognitive abilities by activating mirror neuron systems and promoting synaptic reorganization. AR complements VR by overlaying digital information onto the real world, facilitating functional training in daily living activities. These technologies enhance engagement and efficacy in rehabilitation programs.

Mobile Health (mHealth) Apps

mHealth apps support symptom tracking, medication adherence, and self-management, empowering patients to actively participate in their care. These apps provide user-friendly interfaces, reminders, and progress tracking, which improve adherence and facilitate communication with healthcare providers. mHealth technologies also enable remote monitoring of symptoms and adverse events, optimizing clinical interventions and reducing the need for in-person visits. Their integration with clinical care enhances the continuity and personalization of rehabilitation.

Robotics and Exoskeletons

Robot-assisted gait training (RAGT) and exoskeletons assist severely disabled MS patients in regaining mobility and functional independence. RAGT uses weight support systems and exoskeletons to generate repetitive gait movements, improving gait characteristics, balance, and lower limb stability. These devices reduce spasticity and enhance muscle strength, decreasing fall risk and improving quality of life. Robotic assistants, such as those developed in the RAMCIP project, provide physical and cognitive support at home, demonstrating high acceptance among patients and medical personnel.

Personalization and Adaptive Treatment Plans

Smart rehabilitation emphasizes personalized treatment plans that

adapt to individual symptom profiles, disease progression, and patient feedback. Technologies such as wearable sensors combined with AI-driven analytics enable real-time adjustments in therapy intensity, duration, and modality. For instance, transcranial magnetic stimulation (TMS) parameters are optimized based on individual patient responses to improve spasticity and cognitive function. Similarly, VR and RAGT programs are tailored to target specific motor and cognitive impairments, maximizing efficacy.

Data analytics play a pivotal role in creating dynamic rehabilitation plans. By continuously analyzing patient data, clinicians can modify interventions to match evolving needs, enhancing adherence and outcomes. Integrated systems that combine wearables with AI feedback exemplify this approach, enabling proactive and responsive care. Personalization also extends to lifestyle modifications, including home environment adaptations and assistive devices, which support mobility and independence.

Outcome Measures and Efficacy

Outcome measures (OMs) are essential for tracking progress and informing treatment adjustments in smart rehabilitation. The American Physical Therapy Association's Multiple Sclerosis Outcome Measures Task Force recommends standardized OMs such as the Nine-Hole Peg Test (NHPT) for upper-extremity function, Modified Fatigue Impact Scale (MFIS) for fatigue, Timed 25-Foot Walk test (T25FW) and Multiple Sclerosis Walking Scale (MSWS-12) for gait and walking ability, Multiple Sclerosis Functional Composite (MSFC) for multidimensional assessment, and Six-Minute Walk Test (6MWT) for endurance. These measures provide objective and patient-reported data to quantify symptom severity and treatment effectiveness.

The clinical decision-making process involves selecting OMs based on patient goals, symptom profiles, and clinical utility. For example, a patient with relapsing-remitting MS may be assessed using NHPT, MFIS, T25FW, and MSWS-12 to tailor interventions targeting upper-extremity function, fatigue, and gait. The availability of minimal detectable change data enhances the sensitivity of these measures to treatment effects. While OMs offer valuable insights, their implementation is limited by clinician knowledge and symptom heterogeneity, necessitating further research and standardized core sets for different practice settings.

Future Directions and Ethical Considerations

Emerging trends in smart rehabilitation include brain-computer interfaces (BCIs) and digital twins, which promise to revolutionize MS management by enabling direct neural control of assistive devices and personalized disease modeling. Equitable access to these technologies is critical to ensure that all patients, including underserved communities, benefit from advancements. Ethical considerations such as data security, informed consent, and the risk of over-reliance on technology must be addressed to maintain patient trust and safety.

Collaborative research between technologists, clinicians, and patients is essential to refine smart rehabilitation tools and ensure they meet real-world needs. This interdisciplinary approach will facilitate the development of affordable, accessible, and effective interventions that enhance independence and quality of life for MS patients.

Conclusion

Smart rehabilitation for multiple sclerosis represents a transformative shift in patient care, integrating advanced technologies and personalized treatment plans to address the complex and heterogeneous symptoms of MS. Wearable devices, tele-rehabilitation, AI, VR, robotics, and mHealth apps enable continuous monitoring, tailored interventions, and improved adherence. Personalized plans that adapt in real-time enhance outcomes by targeting individual needs, while standardized outcome measures quantify progress and guide clinical decisions. Despite challenges in accessibility, cost, and patient engagement, the future of smart rehabilitation is promising, with emerging technologies and collaborative research poised to overcome these barriers. By embracing these innovations, healthcare professionals can empower MS patients to achieve greater independence and improved quality of life, ultimately transforming the landscape of MS care.

P184

PRELIMINARY PROTEOMIC ANALYSIS OF HUMAN OSTEOARTHRITIC CHONDROCYTES EXPOSED TO HYDROSTATIC PRESSURE OF VARIOUS MAGNITUDES

M. Cicogni[1], V. Cicaloni[1], P. Nezi[1], L. Salvini[1], S. Cheleschi[1], N. Mondanelli[1], L. Tinti[1], A. Fioravanti[2]

[1]FONDAZIONE TOSCANA LIFE SCIENCES, SIENA, Italy;
[2]Independent Researcher, SIENA, Italy

Objective

The purpose of the present study aimed at investigating the role of possible protein mediators involved in oxidative stress and inflammatory balance in human osteoarthritic OA) chondrocyte exposed to hydrostatic pressure (HP) of various magnitudes a preliminary mass spectrometry–based proteomic analysis.

Material and Methods

Human OA chondrocytes were obtained from femoral heads of patients with coxarthrosis according to ACR criteria, subjected to total hip arthroplasty. For the present study, the cells were subjected for 3 h to cyclic low HP (1–5 MPa) or high continuous static HP (24 MPa) generated by a unique prototype of pressurization system (*Fioravanti, A et al. Indian J. Med. Res. 2010*). Proteomic analysis by mass spectrometry was conducted on cellular lysates before and after pressure treatments of OA chondrocytes Moreover, gene expression levels of oxidative stress markers and of NF-kB pathway were detected by quantitative real-time polymerase chain reaction qRT-PCR. Mitochondrial superoxide anion (O2-) production was detected by flow cytometry.

Results

The data showed that high continuous static HP induced a significant increase of ROS release and of gene expression of specific markers involved in oxidative stress in comparison to basal conditions. Opposite results were obtained with cyclic low HP. Furthermore, the analysis of the p65, p50 and Chuck confirmed the activation of NF-kB pathway in the OA chondrocytes subjected to high continuous static HP in comparison to basal condition and cyclic low HP. Moreover, the bioinformatic analysis of proteomics data revealed, specifically, in chondrocytes stimulated with high continuous static HP, specific proteins that lead to the induction of a pro-inflammatory state and oxidative stress. In contrast, under basal conditions and upon stimulation with cyclic low HP, the expression of protective proteins belonging to inflammatory pathways and associated with oxidative stress was induced.

Conclusions

Although exploratory in nature this study supports the key role of mechanical stress in the development and progression of OA. Furthermore, these data could support the selection of an appropriate physical exercise and the design of optimal rehabilitative programs for patients with OA.

P185

IMPACT OF THE SINGLE NUCLEOTIDE POLYMORPHISM T-786C OF GENE NOS3 ON CLINICAL MANIFESTATION AND CARDIOVASCULAR RISK IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Gaffarova[1], I. Yatskov[1], V. Beloglazov[1], E. Ageeva[1], D. Duryagina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To evaluate the impact of T-786C gene NOS3 polymorphism on clinical characteristics and the CVR formation in patients with AS.
Material and Methods: The study included 176 patients diagnosed with AS. Genotyping was carried out according to the polymorphism of the T-786C gene NOS3 by the polymerase chain reaction method (PCR).
Results: In AS patients with CT genotype it was detected a statistically significantly higher BASMI score (CT 5.0 [4.0; 7.0] vs. CC 4.0 [3.0; 5.0], p<0.001) and uric acid (CT 346.5 [277.0; 446.0] vs. CC 267.0 [212.0; 346.5], p=0.007). Regarding the lipid profile, no statistically significant differences were obtained in the comparison groups (total cholesterol - CC: 5.6 [4.7; 6.3] vs CT: 5.4 [4.4; 6,5], p>0,05; LDL – CC: 3.4 [2.6; 4.0] vs CT 3.5 [3.0; 4,2], p>0,05).
Patients with SNP of CC had a higher incidence of 2nd radiological stage of sacroiliitis (CT 36 (52.9%) vs. CC 72 (69.2%), p=0.031), and in the CT group – 4th radiological stages (CT 20 (29.4%) vs. CC 14 (13.5%), p=0.01). The sacroiliitis stages of the study groups differed at a statistically significant level (p=0.03). There was a higher rate of detection of 0 radiological stage of coxitis (CT 4 (5.7%) vs. CC 2 (2.9%), p=0.001), as well as 3rd (CT 14 (20.0%) vs. CC 12 (11.3%), p<0.05) and 4th radiological stage of sacroiliitis (CT 14 (20.0%) vs. CC 0 (0.0%), p<0.05). The incidence of spondylitis in the patient group was statistically significantly higher in the CT group (CT 34 (52.9%) vs. CC 20 (69.2%), p<0.001).
Detecting the CT genotype in arterial hypertension (AH) (CT 28 (50.0%) vs. CC 32 (33.3%), p<0.05) was significantly more often diagnosed, and in the group of patients with CC genotype.
Conclusion: The predictive role of the CT genotype of NOS3 2786T > C polymorphism in patients with AS was shown not only more pronounced changes in axial spine, but simultaneously increased comorbidity with AH, a key factor of CVR.

P186

ASP229GLY POLYMORPHISM OF THE TLR4 GENE AND CARDIOVASCULAR RISK IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Gaffarova[1], V. Beloglazov[1], I. Yatskov[1], E. Ageeva[1], A. Labozinskaya[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To evaluate the contribution of the Asp229Gly polymorphism of the TLR4 gene to the course and progression of ankylosing spondylitis and conditions associated with cardiovascular risk.

Materials and Methods: The study included 176 patients diagnosed with AS. Genotyping of the Asp229Gly polymorphism of the TLR4 gene was performed using polymerase chain reaction. Results: The lowest BASMI was registered for patients with the AA genotype (AA 4.0 [3.0; 6.0] vs. AG 7.0 [5.0; 9.0] vs. GG 6.5 [5.5; 7.0], p=0.003), and AA homozygotes had the lowest CRP level (AA 6.1 [2.7; 13.5] vs. AG 23.4 [13.6; 33.2] vs. GG 21.5 [7.1; 65.0], p=0.015, p1.2=0.017. AG heterozygotes had the lowest cholesterol value (AA 5.6 [4.6; 6.5] vs. AG 3.2 [3.1; 3.4] vs. GG 5.4 [4.6; 6.7], p=0.044, p1,2=0,001, p2,3=0,004). The highest uric acid level was recorded among patients with GG homozygotes (AA 301.0 [227.0; 415.0] versus GG 426.0 [356.0; 496.0], p=0.039).

The lowest proportion of patients with spondylitis was reliably detected among AA homozygotes (AA 46 (28.7%) versus AG 2 (50.0%) versus GG 6 (75.0%), p1,3=0.005, p=0.016). When comparing the stages of sacroiliitis, carriage of the A allele was associated with a higher frequency of sacroiliitis 2 (AA 104 (65.0%) AG 2 (50.0%) GG 2 (25.0%), p1,3=0.03) and 3 radiographic stages (AA 28 (17.5%) AG 2 (50.0%) GG 0 (0.0%), p2.3=0.029). GG homozygotes had a higher proportion of patients with stage 4 radiographic stage with a small number of carriers of this genotype (AA 28 (17.5%) AG 0 (0.0%) GG 6 (75.0%), p1.3<0.001, p2.3=0.015). In general, the differences in the comparison groups were statistically significant (p=0.001).

Conclusion. Genotyping for the Asp229Gly SNP in the TLR4 gene will allow us to identify groups of AS patients with an increased risk of AS progression and the development of metabolic disorders included in the CVR factors.

P187

REHABILITATION IMPACT ON FUNCTIONAL STATUS IN A PATIENT WITH SPINAL CORD INJURY-RELATED OSTEOPENIA

A. Gherle[1], C. Cseppento Nistor[1], F. Andronie Cioara[1], M. Cevei[1], D. Stoicanescu[2], S. Deac[1], R. Mihut[1]

[1]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania; [2]University of Medicine and Pharmacy "Victor Babes", TIMISOARA, Romania

Objectives: To highlight the impact of cervical spinal cord injury (SCI) on bone mineral density and functional status, and to evaluate the effects of a targeted rehabilitation program in a patient with SCI-associated osteopenia.
Materials and Methods: We report the case of a 45-year-old patient with traumatic cervical SCI at C6–C7, surgically treated with metallic fixation and bone grafting (AIS B, neurological level C7). The patient was admitted for tetraparetic motor deficit, impaired standing and gait, deficits in transfers and activities of daily living (ADLs), sensory disturbances with bilateral upper-limb paresthesia, low back pain. Bone mineral density was assessed using dual-energy X-ray absorptiometry (DXA), while lumbar muscle strength and mobility were evaluated with the Tergumed system (isokinetic testing). Functional status was assessed using the Functional Independence Measure (FIM), Barthel Index, ADL scale, and pain intensity using the Visual Analog Scale (VAS). Assessments were performed at admission and discharge. The patient was hospitalized in our clinic for 14 days. The rehabilitation program included individualized physiotherapy, occupational therapy, Vojta therapy, lumbar spine–specific strengthening, therapeutic massage, and lumbar supportive therapy.
Results: DXA evaluation revealed severe osteopenia at the left hip (T-score −2.4, Z-score −2.2) and osteopenia at the lumbar spine (T-score −1.5, Z-score −1.2). Baseline assessment showed markedly reduced lumbar muscle performance and mobility, with flexion torque of 150.8

Nm, extension torque of 20.9 Nm, and limited lumbar range of motion (72° in flexion and 43° in extension). Following the rehabilitation program, improvements were observed in lumbar muscle strength (flexion increased to 160.8 Nm and extension to 25.6 Nm) as well as in lumbar mobility, with range of motion increasing to 75° in flexion and 46° in extension. Functional evaluation indicated severe dependence (FIM 60/126, Barthel Index 15/100, ADL 2/10). Pain intensity decreased from 4/10 at admission to 2/10 at discharge.

Conclusions: Cervical SCI is associated with early bone mineral density loss, particularly at the hip, contributing to pain and functional impairment. A targeted, multidisciplinary rehabilitation program may improve musculoskeletal performance, reduce pain, and support functional recovery in patients with SCI-related osteopenia, potentially lowering the risk of osteoporosis-related complications.

P188

EVOLVING TRENDS IN SECONDARY PREVENTION OF FRAGILITY FRACTURES: A 2025 COHORT COMPARED WITH A PRE PANDEMIC HISTORICAL COHORT

A. González Ramírez[1], M. A. Hierro Estévez[2], S. Cotobal Rodeles[3], C. Rodríguez Sánchez[2], T. López Pozo[3], A. Gámez Ontaneda[4], U. A. Aguilar Hernández[3], J. F. Blanco Blanco[5], C. Pablos Hernández[3]

[1]Univeristy Hospital of Salamanca / Department of Geriatrics, Salamanca, Spain; [2]University of Salamanca / Medicine Faculty /Department of Medicine, Salamanca, Spain; [3]University Hospital of Salamanca / Department of Geriatrics, Salamanca, Spain; [4]University Hospital of Salmanca / Department of Geriatrics, Salamanca, Spain; [5]University Hospital of Salamanca / Department of Orthopaedic Surgery and Traumatology, Salamanca, Spain

Background: Antiosteoporotic therapy is essential in the secondary prevention of fragility fractures. Over the past decade, clinical practice has evolved with the introduction of new therapeutic options and broader use of potent agents. This study compares a contemporary cohort from 2025 with a prepandemic historical cohort, focusing on demographic and functional characteristics and, particularly, on differences in antiosteoporotic treatment strategies.

Methods: A descriptive comparison was conducted between a 2025 cohort of 258 patients with major fragility fractures and a prepandemic historical cohort of 168 outpatients with symptomatic osteoporosis. Variables analyzed included age, sex distribution, baseline functional status (Barthel Index), and antiosteoporotic treatment prescribed.

Results: The 2025 cohort was older (mean 87.5 ± 6.7 years) than the historical cohort (mean 83.36 ± 5.6 years). Both cohorts showed a predominance of women, more pronounced in the historical group (85,1% vs. 79,4%). Functional status differed substantially: the 2025 cohort exhibited greater impairment (Barthel 71.0 ± 29.6), whereas the historical cohort showed better baseline function (mean Barthel 87,4 ± 16.8). Treatment patterns also diverged. In the 2025 cohort, denosumab was the predominant therapy (75.4%), followed by teriparatide (8.6%), zoledronic acid (3.0%), abaloparatide (5.6%) and romosozumab (1.3%). In contrast, the historical cohort showed a more heterogeneous distribution, with denosumab 57.3%, oral bisphosphonates 30.2%, and teriparatide 6%. Newer osteoformers (abaloparatide, romosozumab) were not available in the prepandemic period. Calcium and vitamin D supplementation was universal in both cohorts.

Conclusions: The 2025 cohort represents an older and more functionally impaired population compared with the prepandemic historical cohort. Despite this, the contemporary cohort received more intensive antiosteoporotic therapy, with a clear predominance of denosumab and the incorporation of newer anabolic agents. Overall use of osteoformers was higher in 2025 (15,5% vs. 6%), reflecting a shift toward more potent and targeted secondary prevention strategies in modern fragility fracture care.

P189

FUNCTIONAL STATUS AND FRAILTY PROFILE OF A COHORT OF PATIENTS RECEIVING ANTI OSTEOPOROTIC TREATMENT IN SECONDARY PREVENTION

M. A. Hierro Estévez[1], A. González Ramírez[2], C. Rodríguez Sánchez[1], U. A. Aguilar Hernández[2], A. Gámez Ontaneda[2], T. López Pozo[2], S. Cotobal Rodeles[2], J. F. Blanco Blanco[3], C. Pablos Hernández[2]

[1]University of Salamanca / Medicine Faculty /Department of Medicine, Salamanca, Spain; [2]University Hospital of Salamanca / Department of Geriatrics, Salamanca, Spain; [3]University Hospital of Salamanca / Department of Orthopaedic Surgery and Traumatology, Salamanca, Spain

Background: Secondary prevention after a major fragility fracture is essential to reduce the risk of subsequent fractures, particularly in very elderly and functionally vulnerable populations. This study describes the clinical characteristics, functional status, and antiosteoporotic treatment prescribed at discharge in a cohort of patients hospitalized for major osteoporotic fractures.

Methods: A descriptive analysis was conducted on 258 patients admitted with major fragility fractures (proximal femur fractures). Sociodemographic variables, fracture type, functional status (Barthel Index, Lawton IADL, FAC, CFS), sarcopenia screening (SARCF), nutritional assessment, and treatment at discharge were collected.

Results: The mean age was 87.53 ± 6.67 years (range 66–102), and 33.6% were admitted from longterm care facilities. Pertrochanteric fractures accounted for 38.8% of cases, subcapital fractures for 35.3%, and other fractures for 25.9%. Among 241 patients assessed for gait support, 60.6% required one or more assistive devices.

Functional assessment showed a mean Barthel Index of 71.04 ± 29.55. Attending to Lawton Index, 63.8% of our sample were dependent for 4 or more instrumental activities. Mobility evaluation according to Functional Ambulation Classification (FAC) revealed that 68.6% scored 4–5 (independent ambulators), while 31.4% scored ≤3. Frailty evaluated by the Clinical Frailty Scale (CFS) was high: 62.4% scored ≥5 (frailty from mild to severe), and 12.9% were classified as vulnerable (score 4). Sarcopenia screening (SARCF) was performed in 84.5% of the cohort, with a modal score of 4 and 14.2% showing symptoms compatible with sarcopenia. Nutritional assessment (n=190) showed that 47.4% of patients evaluated were wellnourished, 38.9% were at risk of malnutrition, and 13.7% were malnourished.

At discharge, 75.4% received denosumab, 8,6% teriparatide, 3.0% zoledronic acid, and 5.6% and 1.3% were prescribed abaloparatide and romosozumab, respectively; 6.3% recieved other therapies.

Conclusions: This cohort represents a very elderly, frail population with high functional dependence and significant prevalence of sarcopenia

and nutritional risk. Despite this complexity, most patients received antiosteoporotic therapy at discharge, with denosumab being the predominant option. These findings highlight the importance of individualized secondary prevention strategies in highrisk older adults following major fragility fractures.

P190

HIGHER BMI ASSOCIATES WITH ELEVATED VEGF, LDL, AND BLOOD PRESSURE IN RHEUMATOID ARTHRITIS

A. Gorlov[1], E. Ageeva[1], V. Beloglazov[1], I. Yatskov[1], V. Kirichenko[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective.
Evaluate the impact of high BMI on biochemical and clinical markers in rheumatoid arthritis (RA).
Material and Methods.
We studied 80 patients with rheumatoid arthritis, assessing 22 serum and clinical markers.
Results.
Women comprised 77.5% of the cohort; mean age was 53.9 years (range 18–73). BMI positively correlated with LDL (ρ=0.430; p<0.001), systolic (ρ=0.544; p<0.001) and diastolic blood pressure (ρ=0.448; p<0.001), and VEGF (ρ=0.296; p=0.008). Stepwise regression identified SBP, age, rheumatoid factor (RF), total cholesterol, and LDL as independent predictors of BMI. The Enter model explained 49.7% of BMI variance ($R=0.705$, $R^2=0.497$, p<0.001). Regression equation:
BMI = 6.820 + 0.112×SBP + 0.088×Age + 0.010×RF − 1.349×Total Cholesterol + 2.091×LDL
Collinearity was acceptable (VIF<2). Total cholesterol was paradoxically higher in participants with lower BMI (p=0.015), likely reflecting cardioprotective HDL or sample size. HDL was not a predictor of BMI (p=0.887).
Cluster analysis based on BMI and RF identified two groups (n=57 and n=23). Cluster 2, with higher BMI and RF, showed elevated VEGF (12.35 vs 11.99 pg/mL; p=0.003), hsCRP (3.63 vs 2.66 mg/L; p=0.003), SBP (144.8 vs 131.4 mmHg; p=0.006), DBP (93.0 vs 82.3 mmHg; p<0.001), and LDL (4.01 vs 2.93 mmol/L; p<0.001). Anti-cyclic citrullinated peptide antibodies were also higher, though not significantly.
Conclusions.
Higher BMI in RA patients is associated with elevated VEGF, hsCRP, LDL, SBP, and DBP. BMI correlates with LDL, blood pressure, and VEGF. Independent predictors of BMI include SBP, age, RF, total cholesterol, and LDL, highlighting the interplay between adiposity, vascular, and inflammatory parameters in RA.

P191

EARLY ONSET OF ANKYLOSING SPONDYLITIS FOLLOWING COVID-19 INFECTION IN AN HLA-B27 POSITIVE YOUNG PATIENT

A. Gremi[1], E. Guci[1], L. Djepaxhija[1], E. Arizi[1]

[1]"Mother Teresa" University Hospital Center, Tirana, Albania

A.Gremi [1] , E.Guci [1],E.Arizi [1] ,L.Djepaxhija [1]
[1] "Mother Teresa" University Hospital Center,Tirana,Albania.

Objective: To report a case of early and agressive onset of ankylosing spondylitis (AS) in a young HLA-B27 positive patient following SARS-CoV-2 infection and to highlight COVID-19 as potential trigger for inflammatory rheumatic disease.
Methods: We describe the clinical presentation,laboratory findings,imaging characteristics and therapeutic management of a young patient who developed inflammatory back pain after confirmed COVID-19 infection.Clinical evaluation focused on features of inflammatory back pain and spinal mobility.Laboratory investigations included complete blood count,inflammatory markers and HLA-B27 testing. Imaging assessment was performed using radiographic examination(X-ray) and magnetic resonance imaging(MRI) of sacroiliac joints. The diagnosis was established according to the Assessment of SpodyloArthritis International Society (ASAS) classification criteria for axial spondyloarthritis. Treatment response was assessed clinically after initation of therapy.
Results: A 23-year old patient with no prior rheumatologic history presented with inflammatory low back pain,nocturnal pain and morning stiffness lasting more than 60 minutes,starting approximately 15 weeks after confirmed COVID-19 infection. The SARS-CoV-2 infection had a mild clinical course and did not require hospitalization. There was no history of peripheral arthritis,psoriasis,uveitis or inflammatory bowel disease. Laboratory evaluation revealed elevated inflammatory markers ,including erythrocyte sedimentation rate of 45 mm/h,C-reactive protein of 139 mg/L and fibrinogen level of 540 mg/dl. HLA-B27 testing was positive,while other autoimmune serologies were negative. X-ray of the sacroiliac joints demonstrates some structural damages and MRI of the sacroiliac joint demonstrated active inflammation, bilateral sacroiliitis,partial fusion of the sacroiliac bones ,consistent with advanced ankylosis.
Initial treatment with nonsteroidal anti-inflammatory drugs ,Methotrexate and physical therapy was insufficient. Due to persistently high disease activity ,biological therapy(Etanercept) was initiated,resulting in clinical improvement.
Conclusions: This case suggests a possible association between COVID-19 infection and the early,aggressive onset of ankylosing spondylitis in genetically predisposed young patients. Persistent inflammatory back pain following SARS-CoV-2 infection should prompt early rheumatologic evaluation and timely initation of appropriate therapy to limit disease progression.

P192

DELAYED DIAGNOSIS OF CLASSICAL HOMOCYSTINURIA PRESENTING WITH CEREBRAL VENOUS THROMBOSIS AND VERTEBRAL FRACTURES

A. Halasheuskaya[1], A. Pachkaila[2], E. Rudenka[1], I. Lazarchyk[2]

[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Homocystinuria (HCU; OMIM #236200) is a rare autosomal recessive disorder caused by a deficiency of the enzyme cystathionine β-synthase (CBS). This genetic defect leads to impaired methionine metabolism with elevated levels of homocysteine and methionine in the blood and urine. Clinical manifestations are variable and include damage of the nervous system (developmental delay, intellectual impairment), visual system (ectopia lentis, myopia), skeletal system (osteoporosis, skeletal abnormalities), as well as life-threatening thromboembolic complications. Diagnosis is based on the detection of hyperhomocysteinemia and confirmed by identifying pathogenic mutations in the *CBS* gene.
Objective: To present a clinical case of late-diagnosed HCU complicated by cerebral venous thrombosis and severe osteoporosis with pathological vertebral fractures.
Case report: At the age of 8 years and 5 months, a female patient with previously diagnosed pectus carinatum and progressive high-grade myopia suddenly developed focal neurological symptoms. Examination revealed cerebral venous thrombosis, significant hyperhomocysteinemia (275 μmol/L), and bilateral lens subluxation. Two months later, back pain manifested. Dual-energy X-ray absorptiometry showed low bone mineral density in the lumbar spine (Z-score -3.6 SD). MRI revealed multiple compression fractures of the vertebrae (T12, L1-L3). Molecular genetic analysis identified compound heterozygous pathogenic variants in the *CBS* gene: c.833T>C (p.Ile278Thr) and c.1498_1499del (p.Ser500AlafsTer38), which definitively confirmed the diagnosis of classical HCU.
Conclusion: This case demonstrates that delayed diagnosis of classical HCU leads to severe complications: thrombosis and osteoporosis. The key diagnostic clue is an unexplained combination of ophthalmological, neurological, and skeletal disorders, necessitating homocysteine level testing. Early pathogenetic therapy and multidisciplinary follow-up are essential for improving the prognosis.

P193

GERODERMA OSTEODYSPLASTICUM: A RARE CAUSE OF SEVERE OSTEOPOROSIS AND VERTEBRAL FRACTURES IN A CHILD

A. Halasheuskaya[1], A. Pachkaila[2], E. Zhukovskaya[2], D. Zaitsau[2]

[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Geroderma osteodysplasticum (GO; OMIM#231070) is a rare autosomal recessive connective tissue disorder caused by mutations in the *GORAB* gene. Its distinctive features include congenital wrinkled, lax skin and severe osteoporosis leading to pathological fractures.
Objective: To analyze the phenotype and features of bone complications (osteoporosis, pathological fractures) in a 17-year-old female patient with GO, discussing key diagnostic aspects through a clinical case presentation.
Case report: Since birth, the patient presented with the characteristic GO features: wrinkled skin, joint hypermobility, congenital hip dislocation, and foot deformities. Her first low-energy fracture (tibia) occurred at 4 months of age. By 15 years of age, her history included multiple low-energy fractures affecting the tibia, femur, and digital phalanges. Spinal pain manifested at age 11. MRI revealed a grade I compression fracture of T12 and wedge deformities of the T10-L2 vertebral bodies. At the age of 17, whole genome sequencing identified compound heterozygous pathogenic variants in the *GORAB* gene: c.332del (p.Pro111fs) and c.631_632del (p.Lys211fs), confirming the diagnosis of HO. Laboratory evaluation at our clinic at age 17 showed normal calcium-phosphate metabolism parameters and bone turnover markers. Dual-energy X-ray absorptiometry (DXA) revealed a lumbar spine BMD Z-score of -1.7 SD and a total body (excluding the head) BMD Z-score of -1.3 SD. Follow-up MRI confirmed an old grade III compression fracture of T12 and grade I wedge deformities of L1-L2 (according to Genant). Bisphosphonate therapy (pamidronic acid) was initiated.
Conclusion: This clinical case demonstrates a key paradox of GO: the development of multiple low-energy and compression fractures of the spine in childhood with borderline BMD values. This indicates a primary impairment in the quality (microarchitecture) of bone tissue, not just its mineral density. This case highlights the need for a comprehensive fracture risk assessment (including spinal MRI) and the importance of genetic testing for the verification of GO in patients with severe osteoporosis and a dysplastic phenotype.

P194

RISK FACTORS FOR OSTEOPOROSIS AND FRACTURES IN RHEUMATOID ARTHRITIS PATIENTS

A. Hasanović[1]

[1]DEPARTMENT OF ANATOMY, FACULTY OF MEDICINE, UNIVERSITY OF SARAJEVO; CLINIC FOR HEART, BLOOD VESSELS AND RHEUMATIC DISEASES, UNIVERSITY CLINICAL CENTRE OF SARAJEVO, SARAJEVO, Bosnia & Herzegovina

Objective: Osteoporosis as a major extra-articular complications of RA, not only increasing the risk of fractures but also impairing functional capacity, quality of life, and life expectancy. The purpose of this investigation was to determine risk factors for osteoporosis (OP) in patients with rheumatoid arthritis (RA).
Matherial and Methods: We recruited 200 RA patients from the Clinic for heart, blood vessels and rheumatic disease of the University Clinical Center in Sarajevo treated between December 2023 to December 2025 with bone mineral density (BMD) results. Participants were categorized into osteoporosis or osteopenia, and normal groups based on lumbar spine or hip bone mineral density (BMD) T-scores. The data were collected from medical records of each patients and association between osteoporosis and related risk factors were recorders. The differences were tested using chi-square and Mann –Whitney tests. The level of statistical significance was set at $p<0,05$.
Results: In this study population 188 women (94%) and 12 men (6%), the mean age of the patients was 58,73±8,56 years, and 76 patients (38%) were in the osteoporotic group (T score ≤-2,5 SD in L2-L4 in the lumbar spine or in the femoral neck). The patients were significant older in the group with RA 62,12±9,52 years, compared to patients without

RA, 55,35±7,63 (p<0,01). RA patients with osteoporosis had a higher frequency of fractures in 28 patients (14%) than those in other group especially fractures of the femur (p<0,01).The average BMI of the patients with RA was significantly lower 28,93±8,32 compared to patients without RA (33,36±4,86) (p<0,05).The patients with low BMD had significantly older age and longer period for corticoids usage.

Conclusion This study reveals female, age, postmenopausal status, low BMI, longer period of corticosteroid usage as major risk factors for osteoporosis in rheumatoid arthritis.

Keywords: rheumatoid arthritis, osteoporosis, fractures, bone mineral density, risk factors of osteoporosis

P195

PATIENT SUPPORT ACTIVITIES BY HEALTHCARE PROFESSIONALS IN OSTEOPOROSIS CARE

A. Hayashi[1,2], S. Sato[3], H. Ohshige[3], M. Nakamichi[1], M. Kato[1], T. Matsuoka[1], K. Nomura[1], M. Kusano[1], T. Ogawa[1], Y. Takeda[1]

[1]Kawasaki Orthopedic and Rheumatology Clinic, Kawasaki City, Kanagawa, Japan; [2]Saiseikai Yokohama City Tobu Hospital, Yokohama city, Kanagawa, Japan; [3]Asahi Kasei Pharma Corporation, Tokyo, Japan

Objective

Low persistence with osteoporosis treatment remains major issue in clinical practice. This study aimed to characterize and classify osteoporosis-related support activities conducted by healthcare professionals involved in osteoporosis care in Japan.

Material and Method

Subjects were healthcare professionals (nurses, pharmacists, physical therapists, etc., excluding physicians) working at orthopedic facilities in Japan, being involved in patient instruction for self-injectable osteoporosis medications within previous 3 months. Anonymous web-based questionnaire survey was conducted to assess implementation status of six support activities defined as important for treatment continuity: In-hospital training, Patient education, Patient communication, Patient list management and follow-up scheduling, Inter-professional collaboration, and promoting follow-up visits. Scores for each activity were standardized, and cluster analysis was performed based on these scores.

Results

A total of 1,053 healthcare professionals responded, including 891 nurses and 66 pharmacists and others. Cluster analysis with heatmap visualization classified respondents into five clusters: Cluster 1 (high implementation of all activities, 23.7%); Cluster 2 (limited Patient list management and follow-up scheduling, with other activities implemented, 16.4%); Cluster 3 (limited Inter-professional collaboration, with other activities implemented, 27.5%); Cluster 4 (limited Patient education and Patient communication, 17.0%); and Cluster 5 (low implementation of most activities, 15.4%).

Conclusion

This study revealed that support activities by healthcare professionals in osteoporosis care in Japan was classified into several characteristic patterns across institutions. These activities can be categorized into “building in-hospital system” and “direct patient-centered approaches”. These findings provide a useful framework for understanding institutional strengths and gaps in osteoporosis support and provides a basis for future research examining the association between support activities and treatment persistence.

Disclosures

This study was conducted in collaboration with Asahi Kasei Pharma Corporation.

CHALLENGES IN SARCOPENIA SCREENING IN KNEE OSTEOARTHRITIS: INTERPRETING SARC-F AND FUNCTIONAL TEST FINDINGS

A. Iniushyna[1], N. Grygorieva[1], N. Zaverukha[1]

[1]SI “D. F. Chebotarev Institute of Gerontology NAMS of Ukraine” Kyiv, Ukraine, Kyiv, Ukraine

Objective: The study aimed to determine whether knee osteoarthritis (KOA) confounds SARC-F screening results, functional performance, and muscle mass assessment, and to evaluate their clinical utility for SP diagnosis for this population.

Methods: A total of 176 women were enrolled: 83 females (control group) without any musculoskeletal disorders (mean age 65.1±7.5 years) and 93 patients with KOA grade 2–3 (Kellgren–Lawrence; mean age 64.9±6.5 years). SP risk was screened using the SARC-F questionnaire. Muscle strength was assessed by handgrip dynamometry and the sit-to-stand test. Muscle mass was measured by whole-body DXA using appendicular lean mass (ALM) and ALM index (ALMI) for calculation.

Results: The groups did not differ in age, height, or waist/hip circumferences. However, women with KOA had higher body weight and BMI (p<0.001). Analysis of SARC-F questions showed a strong association between KOA and difficulty climbing 10 stairs: 50% of patients with KOA reported severe difficulty/inability to perform this test vs 4.6% of controls (p<0.0001), while 4.6% of subjects with KOA reported no difficulty climbing 10 stairs vs 36.2% of controls.

Responses to other questions of the SARC-F questionnaire did not differ significantly between groups, as did the total score of the SARC-F questionnaire. Failure to perform the sit-to-stand test (≥15 sec) was confirmed in 37.5% of subjects with KOA and 16.7% of women of the control group (p=0.0009). Handgrip strength indices did not differ significantly between the groups. Additionally, low ALM and low ALMI rates were similar in both groups.

Conclusion: As SARC-F results do not differ in patients with KOA, it appears suitable for SP screening in this population. The sit-to-stand test may have limited diagnostic value in subjects with KOA and requires further validation. Stair-climbing difficulty appears to be disease-specific, does not affect SARC-F results, and reflects load-bearing joint involvement in KOA.

Disclosures: The authors declared no competing interests.

PIGMENTED VILLONODULAR SYNOVITIS IN THE GLENOHUMERAL JOINT: A RARE BUT AGGRESSIVE ENTITY

A. Ionele Ionescu[1], S. Forner Civera[1], H. Florez[1], R. Jimenez[2], L. Peidro[2]

[1]1 Metabolic Bone Diseases Unit. Rheumatology Department. Hospital Clínic, Barcelona, Spain., BARCELONA, Spain; [2]2 Orthopaedics and Traumatology Department. Hospital Clínic, Barcelona, Spain., BARCELONA, Spain

Objective(s)
To share our clinical experience in diagnosing and managing pigmented villonodular synovitis (PVNS) of the shoulder, highlighting early detection, diagnostic challenges, and individualized treatment strategies.
Material and Methods
A 63-year-old woman presented with progressive right shoulder pain for seven months, without a history of trauma. Initial imaging suggested subacromial pathology: ultrasound demonstrated a full-thickness retracted supraspinatus tear associated with marked joint effusion, while radiographs showed an increased subacromial space. Diagnostic and therapeutic shoulder arthroscopy was performed, revealing diffuse brownish synovial proliferation highly suggestive of PVNS. Histopathological analysis confirmed the diagnosis. An extensive arthroscopic synovectomy combined with rotator cuff repair was undertaken.
Results
Early postoperative evolution was favorable, with pain reduction and functional improvement. However, symptoms recurred six months later. One year after the initial diagnosis, radiographs revealed progressive glenohumeral joint space narrowing and advanced arthropathy. Given the structural deterioration and persistent symptoms, reverse total shoulder arthroplasty was indicated. Intraoperatively, residual PVNS was identified and excised. Postoperatively, the patient experienced rapid pain relief and progressive functional recovery, with satisfactory short-term outcomes.
Conclusions
PVNS is a rare, benign but locally aggressive synovial disorder, most frequently involving the knee (≈80%), with shoulder localization accounting for only 1–2% of cases. Diagnosis relies on clinical suspicion, MRI findings (classically T2 hypointense areas due to hemosiderin deposition) and histopathological confirmation showing hyperplastic synovium with multinucleated giant cells and hemosiderin-laden macrophages. Complete synovectomy remains the first-line treatment; however, diffuse forms are associated with recurrence rates ranging from 20% to 40%. Adjuvant therapies such as radiotherapy or targeted biologic agents (e.g., infliximab, pexidartinib) may be considered in recurrent or unresectable cases. Arthroplasty combined with synovectomy is indicated in the presence of severe joint destruction.
In our case, the clinical interest lies in the uncommon shoulder localization of PVNS and its aggressive evolution despite early arthroscopic management. Progressive glenohumeral arthropathy ultimately required reverse total shoulder arthroplasty, which provided effective pain relief and functional improvement.

DISLOCATION AND MORTALITY AFTER HEMIARTHROPLASTY: UP TO 7-YEAR FOLLOW-UP OF A RANDOMIZED TRIAL AND A TARGET TRIAL EMULATION COMPARING THE DIRECT LATERAL AND POSTEROLATERAL SURGICAL APPROACH

A. J. Rasker[1,8], N. W. Willigenburg[1], M. Tol[1], J. Goslings[1], H. C. Willems[2], M. G. M. Schotanus[3,4], T. Gosens[5,6], L. N. Steenbergen[7], R. W. Poolman[1,8]

[1]OLVG Hospital, Amsterdam, Netherlands; [2]Amsterdam UMC, location University of Amsterdam, Amsterdam, Netherlands; [3]Zuyderland Medical Center, Heerlen, Sittartd-Geleen, Netherlands; [4]School of Care and Public Health Research Institute, Maastricht, Netherlands; [5]ETZ, Tilburg, Netherlands; [6]Tilburg University, Tilburg, Netherlands; [7]Dutch Arthroplasty Register (LROI), 's-Hertogenbosch, Netherlands; [8]Leiden University Medical Center, Leiden, Netherlands

Background
The APOLLO trial reported a higher incidence of dislocation after hemiarthroplasty with the posterolateral approach (PLA) than with the direct lateral approach (DLA) at 6-month follow-up. Whether DLA is associated with long-term disadvantages, such as impaired mobility and potential effects on mortality, remains uncertain and requires longer follow-up and larger sample sizes. We therefore performed a target trial emulation using nationwide registry data, with APOLLO as the target trial.
Methods
We emulated the APOLLO trial using the Dutch Arthroplasty Register, including all adults who underwent hemiarthroplasty for hip fracture between 2018 and 2022 in ten hospitals participating in APOLLO. Eligibility criteria, treatment strategies (DLA vs. PLA), follow-up, and outcome definitions were highly similar to the original trial. Outcomes were revision (all-cause and for dislocation) and all-cause mortality, assessed up to 7 years after hemiarthroplasty.
Results
APOLLO included 843 patients (49% DLA, 51% PLA); the emulated cohort comprised 14,386 procedures (46% DLA, 54% PLA). Revision for dislocation was more frequent after PLA in both datasets (APOLLO: 2.0% vs. 0%; emulation: 1.1% vs. 0.5%). Revision for any reason was also more frequent after PLA (APOLLO: 5.1% vs. 4.2%; emulation: 3.2% vs. 2.3%). ASA scores and all-cause mortality were higher in the emulated cohort than in the target trial, with no meaningful differences between approaches. Two-year mortality was 29.5% after DLA and 29.9% after PLA in the APOLLO trial, and 35.4% and 35.6%, respectively, in the emulation cohort. With longer follow-up, absolute differences in mortality between DLA and PLA increased slightly in favor of DLA, but no statistically meaningful differences were observed.
Conclusions
Neither the target trial nor the emulation revealed long-term disadvantages of DLA in terms of revision or all-cause mortality. These findings support the use of DLA in hemiarthroplasty for hip fracture.

P199

PREDICTORS FOR FALLING WITHIN SIX MONTHS AFTER SURGERY IN PATIENTS WITH HEMIARTHROPLASTY AFTER AN ACUTE FEMORAL NECK FRACTURE

A. J. Rasker[1,2], L. Berghorst[1], N. W. Willigenburg[1], M. Tol[1], R. W. Poolman[1,2], H. C. Willems[3]

[1]OLVG Hospital, Amsterdam, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Amsterdam UMC, location University of Amsterdam, Amsterdam, Netherlands

Background
For patients who underwent hip hemiarthroplasty, usually due to a femoral neck fracture from a fall, subsequent falls can have life-threatening consequences. This study identified predictors for falling in patients from a clinical trial comparing the direct lateral and posterolateral approach.
Methods
Patients were included if they participated in the APOLLO trial. This secondary analysis divided patients into 'fallers' during 6 months follow-up, 'non-fallers,' and 'unknown.' Two logistic regression analyses were conducted: one using variables collected pre-surgery and one using variables available at discharge. The outcome variable 'fallen within 6 months after hemiarthroplasty' was dichotomous.
Results
Among the patients with known fall status, 219 (48%) fell one or more times and 240 (52%) were non-fallers. Fall status was unknown for 384 (46%) of the 843 APOLLO trial participants. Falling was associated with five pre-surgery variables: impaired mobility, ADL difficulties, neurological and pulmonary comorbidities, and dementia. At discharge, falling was associated with impaired mobility, ADL difficulties, and in-hospital complications. The pre-surgery model had an R^2 of 0.217 and an Area Under the Curve (AUC) of 0.730 (95% CI 0.7-0.8), while the discharge model had an R^2 of 0.216 and an AUC of 0.709 (95% CI 0.7-0.8). Both models showed moderate predictive ability for falling.
Conclusions
This study highlights the substantial incidence of falls after hemiarthroplasty for femoral neck fractures and identifies predictors for falling within six months. In-hospital complications emerged as a novel discharge-time predictor and represent a potentially modifiable target for fall prevention. The multidisciplinary team should prioritize fall prevention, and future research should validate prediction models and assess whether fall prevention strategies can effectively reduce falls.

IS THE PHYSICAL PERFORMANCE OF PATIENTS INFLUENCED BY THE SURGICAL APPROACH OF HEMIARTHROPLASTY AFTER A FEMORAL NECK FRACTURE?

A. J. Rasker[1,2], N. W. Willigenburg[1], T. Gosens[3,4], M. J. Heetveld[5], M. G. M. Schotanus[6,7], J. Goslings[1], R. W. Poolman[1,2], H. C. Willems[8], M. Tol[1]

[1]OLVG Hospital, Amsterdam, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]ETZ, Tilburg, Netherlands; [4]Tilburg University, Tilburg, Netherlands; [5]Spaarne Gasthuis, Haarlem, Netherlands; [6]Zuyderland Medical Center, Heerlen, Sittartd-Geleen, Netherlands; [7]School of Care and Public Health Research Institute, Maastricht, Netherlands; [8]Amsterdam UMC, location University of Amsterdam, Amsterdam, Netherlands

Background

After a hip fracture, patients are at increased risk of recurrent falls and related injuries. Postoperative physical performance is an important determinant of this risk. This study evaluated whether surgical approach influences postoperative physical performance after cemented hemiarthroplasty for femoral neck fractures.
Methods

The study population was a subsample of a prospective nationwide multicenter randomized controlled trial comparing the direct lateral approach (DLA) and the posterolateral approach (PLA) after hemiarthroplasty. Physical performance was assessed 3–4 months postoperatively using the Short Physical Performance Battery (SPPB; range 0–12, higher scores indicate better performance). Secondary outcomes included fear of falling measured with the Falls Efficacy Scale–International (FES-I; range 16–64) and fall-related emergency room visits. Trial registration: NCT04438226.
Results

Seventy patients were included (35 DLA, 35 PLA). Mean SPPB score was 6.6 (SD 2.9) after DLA and 7.6 (SD 3.0) after PLA, corresponding to a mean difference of 1.03 points on the 12-point SPPB scale (95% CI −0.37 to 2.48). No statistically significant difference was observed in total SPPB score. Gait speed was faster after PLA compared with DLA (median 4.06 vs. 4.53 seconds, p=0.035). Fear of falling at 3 months was higher after DLA than after PLA (mean FES-I score 35.9 vs. 26.9, p<0.05). No between-group difference was observed in fall-related emergency room visits during follow-up.
Conclusion

Although no statistically significant difference was observed in overall physical performance, patients treated with PLA showed faster gait speed and lower fear of falling. The observed difference of approximately one point on the SPPB may be clinically relevant for early functional recovery after hip fracture.

P201

PHOSPHATURIC MESENCHYMAL TUMOR LOCALIZATION USING GA-68-DOTATATE PET/CT

C. Hoong[1], A. Jancuska[1], M. Drake[1], S. Broski[1], J. Sfeir[1]

[1]Mayo Clinic, Rochester, United States

INTRODUCTION
Oncogenic osteomalacia, also known as tumor-induced osteomalacia (TIO), is an uncommon paraneoplastic syndrome characterized by hypophosphatemia resulting from phosphaturic mesenchymal tumors (PMT) that secrete elevated levels of fibroblast growth factor 23 (FGF23). Conventional imaging techniques have demonstrated limited efficacy in localizing FGF23-secreting tumors. This report examines the diagnostic utility of Gallium 68-DOTATATE PET/CT (Ga-68-DOTATATE) in the localization of PMT.
METHODS
A prospective recruitment and retrospective chart review was performed

involving 34 patients with suspected TIO who underwent Ga-68-DOTATATE imaging between 2017 and 2025. Imaging findings were correlated with histopathology and/or clinical follow-up to establish the final diagnosis.
RESULTS
The most frequently reported presentations were insufficiency fractures (56%) and muscle and bone pain (50%). The median phosphorus level at presentation was 1.7 mg/dL (IQR 1.4–2.1 mg/dL). All participants exhibited normal serum calcium (IQR 8.9–9.6 mg/dL), with a median parathyroid hormone (PTH) level of 62 pg/mL (IQR 58–137 pg/mL). Median intact FGF23 concentration was 325.5 pg/mL (IQR 102.75–803 pg/mL). The median interval from symptom onset to TIO diagnosis was 2.5 years.
Patients underwent an average of two prior imaging modalities before Ga-68-DOTATATE, including whole-body sestamibi scans, octreotide scans, MRI, and FDG-PET CT. Ga-68-DOTATATE successfully identified a PMT in 19 cases, with a mean SUVmax of 16.8 (±10.9). The sensitivity, specificity, and accuracy of Ga-68-DOTATATE were 86.4%, 83.3%, and 85.3%, respectively. Multivariable analysis indicated that the presence of DOTATATE-avid fractures was significantly associated with a localizing scan (OR 9.45, 95% CI 1.33–98.4, p=0.003).
CONCLUSION
Ga-68-DOTATATE demonstrates high accuracy for PMT localization and offers superior sensitivity when compared to FDG PET/CT. It may be considered as a first-line modality for localizing lesions in patients with TIO. Timely diagnosis facilitates the prevention of chronic hypophosphatemia consequences and enables curative intervention. Although DOTATATE-avid fractures can result in false positives, they may also correlate with a greater likelihood of obtaining a localizing scan.

P202

DECREASED KIDNEY FUNCTION IS ASSOCIATED WITH LOWER L1 DENSITY ON OPPORTUNISTIC COMPUTED TOMOGRAPHY: COMPARISON OF DIFFERENT CLINICALLY AVAILABLE TOOLS

A. Jančuška[1], R. Králik[1], J. Payer[1], M. Kužma[1]

[1]5th Department of Internal Medicine, Faculty of Medicine, Comenius University in Bratislava, University Hospital Bratislava, Ružinov, Bratislava, Slovakia

Introduction
Chronic kidney disease–mineral and bone disorder (CKD-MBD) patients have different outcomes compared to common osteoporosis patients, and reliable diagnostic tools for determining prognosis and guiding therapy are not clearly established. Measurement of bone density from opportunistic computed tomography (CT) is a promising novel diagnostic tool.
Objective
Comparison of different clinically available bone parameters: areal bone mineral density (aBMD), trabecular bone score (TBS), 3D-densitometry (3D-DXA) and density of L1 vertebral body from opportunistic CT across CKD subjects defined by estimated glomerular filtration rate (eGFR).
Material and Methods
A cross-sectional study of all subjects that underwent a CT scan including the L1 vertebra, DXA and eGFR measurements (within 6 months interval) between years 2020-2025. The associations between eGFR and bone parameters: CT density of L1 vertebra, BMD at lumbar spine, neck and total femur, trabecular bone score (TBS) and 3D DXA, where trabecular and cortical volumetric BMD, surface BMD and cortical thickness were assessed. Patients were analysed within specific CKD stages and division of eGFR quartiles was done.
Results
From a total number of abdominal and thoracic CTs (n=29473), of which 280 subjects also underwent DXA, a total number of 134 patients who had all DXA parameters available in both the femur and the lumbar spine, eGFR measurement and a fully accessible L1 vertebra body for on the CT, were analysed. From those, 98 were women (73,1%) and 36 men (26,9%), with median age 66 years. Among all bone parameters, L1 CT density showed a significant difference, between Q1 (mean 145,6 HU) and Q4 (median 92,2 HU, p=0,004). Associations between CT L1 density (Spearman ρ=0,308, p=0,0009), BMI (Spearman ρ=-0,26, p=0,0048), age (Spearman ρ=-0,509, p<0,0001) and eGFR were observed. No difference in discrimination between CKD stages or quartiles when adjusted for age and BMI was observed.
Conclusion
This study shows significant association between eGFR and L1 body CT density which is stronger than DXA parameters. Although the association was significantly influenced by age and BMI, what is clearly a limitation, as well as small sample size, opportunistic CT shows a rich and underutilised source of diagnostic data and warrants further investigation.

P203

POST-DISCHARGE OUTPATIENT BALANCE TRAINING PROVIDES COMPARABLE FUNCTIONAL RECOVERY TO EARLY INPATIENT TRAINING AFTER FRAGILITY HIP FRACTURE SURGERY

K. Jirawatthanasakda[1], S. Palee[2], P. Singkheaw[3], S. Inkate[3], C. Ratchatasot[1], W. Chonlapatnapatsiri[1], A. Jarusriwanna[4]

[1]Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [2]Department of Rehabilitation Medicine, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [3]Department of Family Medicine, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [4]Department of Orthopaedics, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand

Objectives: Postoperative rehabilitation after fragility hip fractures is essential for recovery, and beyond early mobilization, intensive balance training may further improve functional outcomes. However, evidence comparing the optimal timing and setting of intensive balance training remains limited. This study aimed to compare functional outcomes in patients undergoing fragility hip fracture surgery who received early intensive inpatient balance training versus outpatient balance training after hospital discharge.
Material and Methods: This retrospective cohort study included patients aged ≥60 years who underwent surgery for fragility hip fractures, including intertrochanteric and femoral neck fractures. Patients were classified according to rehabilitation pathway: an inpatient group initiating intensive balance training during hospitalization and an outpatient group receiving a comparable program after discharge. Functional recovery was assessed using the Barthel Index at baseline (postoperative) and at 1, 3, and 6 months. Longitudinal outcomes were analyzed using multilevel Gaussian models accounting for repeated measures, with adjustment for age, sex, body mass index, Charlson Comorbidity Index, baseline functional status, and surgical variables. Predictive margins

and adjusted mean differences were estimated. Secondary outcomes included the EuroQol visual analogue scale (EQ-VAS) and postoperative ambulatory status.
Results: Of 85 eligible patients, 3 were excluded, leaving 82 for analysis: 39 in the inpatient group (47.6%) and 43 in the outpatient group (52.4%). Barthel Index scores improved over time in both groups, and predictive margins demonstrated progressive recovery across follow-up. In crude analysis, inpatient rehabilitation was associated with an 11.2-point higher Barthel Index than outpatient rehabilitation (95% CI 2.3 to 20.1). After adjustment, the mean difference decreased to 4.5 points (95% CI −3.5 to 12.6) and was not statistically significant (p>0.05). EQ-VAS and ambulatory status were also not significantly different between groups.
Conclusion: Intensive outpatient balance training after hospital discharge achieved functional recovery comparable to early intensive inpatient balance training. These findings suggest that outpatient balance training may be a resource-efficient alternative while maintaining patient outcomes and potentially reducing hospital utilization.

P204

PREHOSPITAL DELAY IS ASSOCIATED WITH INCREASED 1-YEAR MORTALITY AFTER FRAGILITY HIP FRACTURE SURGERY

P. Chanthanapodi[1], J. Patumanond[2], S. Lawanaskol[2], P. Atthakomol[3], N. Kitcharanant[3], A. Jarusriwanna[4]

[1]Sawan Pracharak Hospital, Nakhon Sawan, Thailand; [2]Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [3]Department of Orthopaedics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand; [4]Department of Orthopaedics, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand

Objectives: Timely management of fragility hip fractures is essential, as treatment delays are associated with adverse outcomes. Although time to surgery after hospital admission has been widely studied, the effect of the prehospital phase, defined as the interval from injury to hospital arrival, remains less well established. This study aimed to evaluate the association between prehospital timing and postoperative outcomes in older adults with fragility hip fractures.
Material and Methods: This confirmatory prognostic factor study used a retrospective cohort design. Patients aged ≥60 years with fragility hip fractures (intertrochanteric or femoral neck fractures) who underwent surgical intervention were included. Patients were categorized into a delayed-arrival group (>24 hours) and a control group (≤24 hours). Outcomes included postoperative complications, length of hospital stay, and mortality at 30 days and 1 year. Statistical analyses included exact tests, t-tests, and adjusted risk regression models to account for potential confounders.
Results: A total of 393 patients were included, of whom 61 (15.5%) experienced prehospital delays >24 hours and 332 (84.5%) arrived at the hospital within 24 hours. Postoperative complications occurred in 44.1% of the delayed group and 50.7% of the control group (adjusted risk ratio 0.87, 95% CI 0.64 to 1.17, p=0.059). Length of hospital stay was not significantly different between groups (mean difference -0.73 days, 95% CI -1.63 to 0.17, p=0.112). Similarly, 30-day mortality was comparable between groups (1.74% vs 3.21%, p=0.437). In contrast, 1-year mortality was significantly higher in the delayed group (29.3% vs 17.4%, p=0.049).
Conclusions: Prehospital delays exceeding 24 hours were associated with a significantly increased risk of 1-year mortality in older adults with fragility hip fractures, despite no significant differences in short-term complications or 30-day mortality. These findings underscore the importance of early hospital presentation after injury to improve long-term survival outcomes.

P205

WHAT ARE THE PREDICTIVE FACTORS OF A GOOD RESPONSE TO ANTI-TNFA THERAPY IN PATIENTS WITH SPONDYLOARTHRITIS?

A. Jerbi[1], Z. Gassara[1], A. Feki[1], S. Ben Jmeaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]service de Rhumatologie CHU Hedi Chaker, Sfax, Tunisia

Introduction:
Spondyloarthritis (SpA) encompasses a group of chronic inflammatory rheumatic diseases that primarily affect the axial skeleton, but also involve the entheses and peripheral joints. The aim of this study was to identify the sociodemographic, clinical, and paraclinical factors associated with a good response to anti-TNFα therapy in patients with SpA.
Materials and Methods:
This was a retrospective, descriptive, and analytical study including patients with SpA, regardless of the clinico-radiological phenotype, who received anti-TNF therapy for more than six months. Sociodemographic, clinical, biological, and radiological data were collected. The clinico-biological therapeutic response was assessed using the ASDAS-ESR score at baseline, 6 months, and 12 months. A p-value < 0.05 was considered statistically significant.
Results:
Fifty-five patients were included, with a mean age of 48.3 ± 10.8 years [28–69] and a male predominance (M/F = 1.39). The mean age at symptom onset was 32 ± 10 years [19–56], at diagnosis 36 ± 10 years [19–60], and at initiation of biologic therapy 44 ± 10 years [21–67]. The median disease duration before starting biologic therapy was 17 years [2–49]. Four patients (7.2%) reported a family history of SpA.

Regarding disease phenotype, 41 patients (74.5%) had primary axial and radiographic ankylosing spondylitis, 7 (12.7%) had psoriatic arthritis, and 7 (12.7%) had SpA associated with inflammatory bowel disease (5 cases of Crohn's disease and 2 of ulcerative colitis). Coxitis was identified in 38.2% of cases (n = 21) and uveitis in 14.5% (n = 8). HLA-B27 was positive in 65.5% of patients (n = 36).

As for biologic treatment, 26 patients (47.3%) received infliximab, 11 (20%) adalimumab, 10 (18.2%) certolizumab, 6 (10.9%) etanercept, and 2 (3.6%) golimumab. The mean ASDAS-ESR values before initiation of biologic therapy, at 6 months, and at 12 months were 3.2 ± 0.7, 2.4 ± 0.6, and 2.3 ± 0.8, respectively.
No significant correlation was found between the decrease in ASDAS-ESR scores at 6 and 12 months and age, sex, educational level, smoking status, disease duration, SpA phenotype, HLA-B27 or antinuclear antibody positivity. However, a high body mass index (BMI) was correlated with significantly higher ASDAS-ESR scores at 6 and 12 months (p = 0.015 and 0.02, respectively) compared to patients with normal weight, while higher baseline CRP and ESR levels predicted a better response to anti-TNFα therapy at 6 and 12 months (p = 0.003 and 0.004).
Conclusion:
High baseline CRP and ESR levels appear to be potential predictive markers of a good response to anti-TNFα therapy, whereas a high BMI was associated with reduced therapeutic efficacy.

P206

INDOMETHACIN-INDUCED GRANULOMATOUS HEPATITIS: A RARE BUT REAL CASE

A. Jerbi[1], Z. Gassara[1], A. Feki[1], S. Ben Jmeaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]service de Rhumatologie CHU Hedi Chaker, Sfax, Tunisia

Introduction

Granulomatous hepatitis is a rare histopathological entity with various etiologies, characterized by the presence of epithelioid and giant-cell inflammatory granulomas within the liver tissue. Although drug-induced causes are uncommon, they should be considered after excluding other etiologies. We report here a rare case of granulomatous hepatitis secondary to indomethacin use in a patient followed for ankylosing spondylitis (AS).

Case Description

Mrs. F, 65 years old, diabetic, has been followed for AS with bilateral coxitis since 2010, treated with non-steroidal anti-inflammatory drugs (NSAIDs), specifically indomethacin at a dose of 100–150 mg/day. Due to persistent disease activity (ASDAS-CRP = 3.4; BASDAI = 6.2; Lequesne index (hips) = 11), initiation of biological therapy was considered.

Pre-therapeutic workup revealed significant biological inflammation (ESR = 120 mm/h, CRP = 100 mg/L, serum protein electrophoresis showing polyclonal hypergammaglobulinemia) and moderate cholestasis (GGT and ALP approximately twice the normal value without cytolysis). Infectious workup (tuberculosis screening, viral hepatitis serologies, Wright test, syphilis and toxoplasmosis serologies) was negative.

Thoraco-abdomino-pelvic (TAP) CT scan showed homogeneous hepatosplenomegaly without portal hypertension. Antinuclear antibodies (ANA) were positive (titer: 1/160), while anti-smooth muscle (anti-SMA), anti-SLA, and anti-LKM1 antibodies were negative. Liver biopsy revealed a portal and periportal lymphocytic infiltrate with non-caseating epithelioid granulomas, without giant cells. Histological examination confirmed the absence of fibrosis, cirrhosis, or malignant tumor cells.

Given this histological pattern of granulomatous hepatitis, primary biliary cholangitis (PBC) was considered, but antimitochondrial antibodies, anti-gp210, and anti-sp100 antibodies were negative. Sarcoidosis was also suspected, but phosphocalcic balance was normal, the TAP scan showed no lymphadenopathy or pulmonary infiltrates, and angiotensin-converting enzyme levels were normal.

Drug-induced etiology was suspected due to chronic high-dose indomethacin use as self-medication. Indomethacin was discontinued, resulting in a progressive normalization of GGT and ALP levels, with complete normalization after 4 months. Pharmacovigilance investigation identified indomethacin as responsible for the hepatic injury. The patient was subsequently started on secukinumab 150 mg/month, achieving satisfactory control of her rheumatologic disease (ASDAS-CRP = 2.2) and stable liver function tests.

Conclusion

Granulomatous hepatitis is associated with a heterogeneous group of conditions, primarily including primary biliary cholangitis, tuberculosis, sarcoidosis, and hepatitis B and C. Drug-induced cases, particularly related to NSAID use, are rare and often facilitated by self-medication exceeding recommended doses and duration, highlighting the crucial importance of therapeutic education.

P207

PREVALENCE OF ANTINUCLEAR ANTIBODIES AND CORRELATION WITH CLINICAL ACTIVITY IN RHEUMATOID ARTHRITIS

A. Jerbi[1], Z. Gassara[1], M. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : Rheumatoid arthritis (RA) is a systemic autoimmune disease primarily affecting the joints. Although specific autoantibodies such as rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) are well characterized, antinuclear antibodies (ANAs)—traditionally associated with connective tissue diseases—are frequently detected in isolated RA. their exact prevalence and clinical and prognostic value in this disease remain poorly defined. The aims of this study were to determine the prevalence and characteristics of ANAs in RA and to evaluate their association with disease activity.

Patients and Methods : We conducted a retrospective, descriptive, and analytical study including RA patients according to the 2010 ACR–EULAR criteria, after excluding any associated connective tissue diseases. Demographic, clinical, and biological data (RF, ACPA, and ANAs by indirect immunofluorescence on HEp-2 cells) were collected. Disease activity was assessed using DAS28 score. A value of $p<0.05$ was considered statistically significant.

Results : A total of 140 patients were included, with a mean age of 51 ± 14 years and a sex-ratio F/M of 3. The median duration of the disease was 11 years[1-35]. RF was positive in 80% of patients (n=112), with a mean level of 354±120 IU/mL and ACPA in 60% (n=84), with a mean level of 74.8±25 IU/mL. RA was erosive with radiographic carpal involvement in 98.5% (n=138). All patients were receiving methotrexate at a mean dose of 14.8±3.4 mg/week. NSAIDs and corticosteroids were used in 98% and 84%, respectively. The mean DAS28-CRP was 4.1±0.9 and the DAS28-VS was 4.9±1.1. ANAs were positive in 62.1% (n=87), with titers ranging from 1:160 (15.7%) to 1:1280 (9.2%). Speckled fluorescence was most frequent (88.5%). All ANA+ patients were anti-dsDNA negative. Among 40 ANA+ patients tested for extractable nuclear antigens, 15% were positive, mainly anti-SSA (38%), anti-Ro52 (38%) and anti-SSB (19%). ANA+ patients showed a non-significant trend toward higher DAS28 (OR=1,94 ; p=0,09).

Conclusion : Our study demonstrated that ANAs positivity is common in RA without associated connective tissue diseases, reflecting a broader autoimmune profile. However, their presence was not significantly associated with higher disease activity, indicating that ANAs do not appear to be a reliable prognostic marker in RA.

P208

PREVALENCE OF HYPERCALCEMIA AND HYPOCALCEMIA IN HIGH-RISK GROUPS IN THE RUSSIAN FEDERATION

M. I. Fadeeva[1], A. M. Gorbacheva[1], A. K. Eremkina[1], N. G. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia, Moscow, Russia

Objectives: Assess prevalence of hyper- and hypocalcemia in high-risk of osteoporosis and low-energy fractures groups.
Material and methods: We conducted a blood calcium screening analysis using data obtained from primary healthcare facilities across six regions of the Russian Federation between November 2024 and June 2025. The study targeted individuals aged 50 years and older, women included in the study were in menopause. Patients enrolled the study during routine preventive check-ups and health screenings. Measurements included total calcium and albumin levels. Laboratory tests were performed at the participating healthcare facilities.
Results: Among 11,830 screened individuals the overall prevalence of calcium metabolism disorders was 29.1%. Hypercalcemia was detected in 3.3% of participants, while hypocalcemia was present in 25.8%. Hypercalcemia was more frequent in women (3.5%) compared to men (2.7%), whereas hypocalcemia was higher in men (28.0% vs. 25.0% in women). The prevalence of both hyper- and hypocalcemia exceeded the average in older age groups: among individuals aged 70–79.9 years, elevated albumin-corrected calcium was found in 3.9% and decreased levels in 28.3%; in those over 80, elevated albumin-corrected calcium was found in 6.6% and decreased levels in 26.8%. Gender-specific analysis showed the highest hypercalcemia rates in individuals over 80 years (women 7.2%, men 4.9%), while hypocalcemia peaked in the 70–79.9-year age group (women 27.4%, men 31.2%).
Conclusions:
Calcium metabolism disorders are clinically significant and highly prevalent: both hyper- and hypocalcemia are often secondary to serious underlying conditions and can lead to life-threatening complications. However, epidemiology of hyper- and hypocalcemia in the Russian Federation is poorly understood. As this research showed calcium imbalance is widespread among individuals over 50 and postmenopausal women in the Russian Federation, with prevalence varying significantly by age and sex. In the Russian Federation, serum calcium is not routinely measured in clinical practice because it is not included in standard biochemical panels. These findings highlight the need for implementing targeted screening programs in high-risk populations to enable early detection and intervention.

P209

THE COMPREHENSIVE INVESTIGATION OF THE DIFFERENTIAL EXPRESSION PROFILE OF CORONARY ARTERY DISEASE AND OSTEOPOROSIS

A. Kakavand Hamidi[1], F. Razi[1], M. Mohammad Amoli[1]

[1]Tehran University of Medical Sciences, Endocrinology and Metabolism Research Institute, Tehran, Iran

Objective
The objective of this study is to identify the still unclear specific differentially expressed genes (DEGs) linking Coronary artery disease (CAD) and osteoporosis, including the involved pathways.
Material and Methods
Fourteen datasets were selected from the Gene Expression Omnibus (GEO), with 7 datasets for each CAD or osteoporosis group. Datasets in each group were analyzed to identify Differentially Expressed Genes (DEGs) using the GEOquery and limma packages in R. Also, Batch effects were removed, and datasets were merged in each group using the sva package. Adj.P.Val (FDR) cut-off of less than 0.05 and |log2 foldchange| ≥ 0.5 were used for recognizing the up- and down-regulated genes within each group of study. Cross-group DEGs overlap was evaluated using Rank-Rank Hypergeometric Overlap (RRHO) Analysis in R, and the common DEGs were under an overrepresentation enrichment analysis to connect the DEGs with pathways. Protein-protein network analysis and hub gene identification using STRING and Cytoscape were also conducted.
Results
Final results showed that 56 statistically significant common DEGs were reached between the two groups. The results of Enrichr-KG enrichment highlighted the regulation of mitotic cell cycle phase transition (GO:1901990) as the most significant term (P-value<0.05) across the gene set. Panther GO enrichment analysis also showed biological process (BP), including negative regulation of cardiac muscle cell myoblast differentiation (GO:2000691) as one of the ten top significantly enriched BP. Network analysis identified two hub genes according to degree centrality, closeness centrality, and maximal clique centrality (MCC), namely, BUB1B and CCNB1.
Conclusions
The implication of BUB1B or RUB1 in a variety of biological processes, such as aging and pathologies like heart disease, is re-identified in our study, and as one of the genes linking heart disease and osteoporosis through its activity involved in spindle checkpoint function and proper chromosome segregation during cell proliferation. As CCNB1 is also involved in cell mitosis regulation in accordance with BUB1B, it can be suggested as a new gene linking CAD and osteoporosis via the same mechanism.

P210

HANDGRIP STRENGTH MAY OVERESTIMATE SARCOPENIA IN PATIENTS WITH HAND OSTEOARTHRITIS: A PILOT STUDY

A. Kalbiyeva Abdullayeva[1], M. Ozturk[1], R. Terlemez[1]

[1]Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, PM&R Department, Istanbul, Türkiye

Objective
To evaluate the relationship between handgrip strength, lower extremity muscle mass, and functional performance, and to explore the potential limitations of handgrip-based sarcopenia screening in patients with hand osteoarthritis.
Material and Methods
This pilot cross-sectional study included 10 patients diagnosed with hand osteoarthritis according to the EULAR classification criteria (1). Handgrip strength of the dominant hand was assessed using a dynamometer and lower extremity functional performance was evaluated using the Chair Stand Test (CST). In accordance with the iSarcoPRM diagnostic algorithm, impairment in either handgrip strength or CST performance was considered suggestive of probable sarcopenia and prompted further

evaluation. In patients requiring further evaluation, lower extremity muscle mass was assessed using the Sonographic Thigh Adjustment Ratio (STAR) based on quadriceps muscle thickness adjusted for body mass index (BMI), with values <1.0 for females indicating sarcopenia (2).

Results

Low handgrip strength was identified in 9 patients; however, all demonstrated normal CST performance. According to the STAR, sarcopenia was not confirmed in 7 of these patients. Despite reduced handgrip strength, quadriceps muscle thickness adjusted for BMI, as assessed by the STAR, remained within normal limits in the majority of cases.

Conclusion

Handgrip strength may overestimate sarcopenia in patients with hand osteoarthritis. Reduced handgrip strength in this population does not necessarily reflect impaired lower extremity muscle mass or functional performance. Therefore, reliance on handgrip strength alone may be misleading. Incorporating lower extremity assessments within the iSarcoPRM diagnostic algorithm may improve the accuracy of sarcopenia screening in patients with hand osteoarthritis.

DEVELOPMENT AND VALIDATION OF THE PEDIATRIC OSTEOPOROSIS KNOWLEDGE ASSESSMENT FOR PHYSICIANS (POKAP)

A. Keles[1], E. Giray[1], O. G. Illeez[1], P. Akpinar[1], F. Unlu Ozkan[1], I. Aktas[1], S. Tuzun[2], E. Karadag Saygi[3], S. Aktas[4]

[1]University of Health Sciences, Fatih Sultan Mehmet Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Istanbul, Türkiye; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Physical Medicine and Rehabilitation, Istanbul, Türkiye; [3]Marmara University, Department of Physical Medicine and Rehabilitation, Istanbul, Türkiye; [4]University of Health Sciences, Hamidiye Faculty of Medicine, Department of Biostatistics and Medical Informatics, Istanbul, Türkiye

Objective

To develop and psychometrically validate a physician-targeted instrument designed to assess knowledge of pediatric osteoporosis.

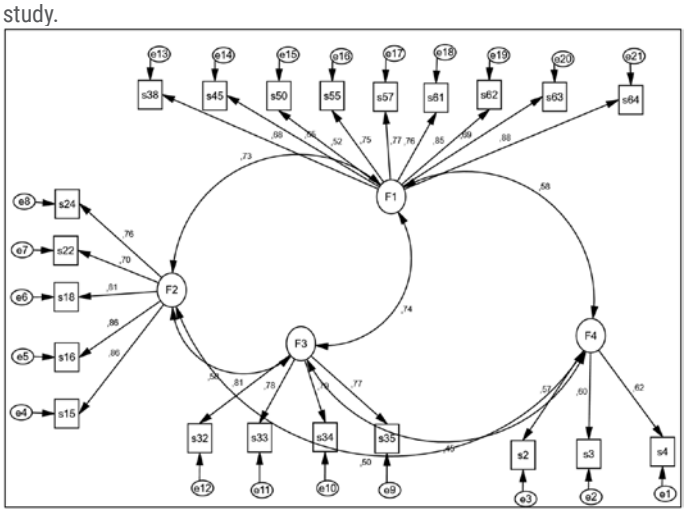
Materials and Methods

This cross-sectional methodological study was conducted in Turkey between September and November 2024. The Pediatric Osteoporosis Knowledge Assessment for Physicians (POKAP) was developed based on evidence-based guidelines and expert consensus. An initial pool of 64 items was generated and evaluated for content validity by an expert panel, followed by item reduction and psychometric analyses. The questionnaire was administered online to 321 physicians from specialties involved in pediatric osteoporosis care. These included Physical Medicine and Rehabilitation, Orthopedics, General Pediatrics, and pediatric subspecialties such as endocrinology, metabolism, neurology, nephrology, and gastroenterology. Construct validity was examined using exploratory and confirmatory factor analyses, and internal consistency was assessed using Cronbach's alpha. Model fit was evaluated using the chi-square/degrees-of-freedom ratio (CMIN/df), goodness-of-fit index (GFI), adjusted GFI (AGFI), root mean square residual (RMR), root mean square error of approximation (RMSEA), and information criteria (AIC and BIC).

Results

Content validity analysis reduced the initial 64-item pool to 34 items, yielding a scale-level content validity index of 0.796. Exploratory factor analysis demonstrated excellent sampling adequacy (KMO = 0.925; Bartlett's test $p < 0.001$) and supported a four-factor structure explaining 63.43% of the total variance, with factor loadings ranging from 0.497 to 0.837. Confirmatory factor analysis confirmed good model fit (CMIN/df = 1.837, GFI = 0.901, AGFI = 0.874, RMSEA = 0.051). The final 22-item POKAP showed excellent internal consistency (Cronbach's α = 0.914), with subscale alpha values ranging from 0.643 to 0.894.

Conclu



POKAP is a valid and reliable instrument for assessing pediatric osteoporosis knowledge among physicians. Its multidimensional structure allows both overall and domain-specific evaluation of knowledge and may be useful for educational needs assessments, training programs, and future research aimed at improving pediatric bone health care.

DESIGNING INCLUSIVE MOBILE GOVERNMENT SERVICES IN THE MIDDLE EAST: A USER EXPERIENCE–CENTERED FRAMEWORK

A. Khamaj[1]

[1]Jazan University, Jazan, Saudi Arabia

Mobile government (m-government) services constitute a central pillar of digital transformation strategies across the Middle East. Governments in the region have invested extensively in mobile platforms to improve public service efficiency, accessibility, and citizen engagement. Despite these efforts, adoption and sustained use of m-government services remain uneven, largely due to user experience (UX) challenges. This paper presents a comprehensive investigation of UX issues affecting mobile government services in the Middle Eastern context. Drawing on an extensive review of academic literature, regional digital government reports, and empirical UX studies, the paper identifies key usability, accessibility, linguistic, cultural, and trust-related barriers. Based on these findings, a contextualized UX framework is proposed to guide the design of inclusive, usable, and culturally responsive m-government services. The study contributes to both theory and practice by extending UX discourse into non-Western public sector contexts and offering actionable guidance for policymakers and designers.

INFLUENCE OF TREATMENT PATIENTS WITH RHEUMATOID ARTHRITIS ON COMPLICATIONS IN TOTAL JOINT ARTHROPLASTY

E. Naryshkin[1], A. Khramov[1], M. Makarov[1], S. Maglevaniy[1], T. C. Phan[1], A. Dubinin[1], V. Nesterenko[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Abstract

Introduction: Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications. This is due to the presence of prolonged therapy with glucocorticoids, disease-modifying and genetically engineered biological drugs, osteoporosis, as well as the activity of the underlying disease

Objective: To conduct a comparative analysis of the effect of RA treatment on local complications, such as periprosthetic infection, periprosthetic fractures, wound complications, ligamentous disorders in total joint arthroplasties (TJA) in patients with RA.

Materials and methods: 1113 TJA (649 and 464 total knee and hip replacements) in patients with RA, which were performed in the period from 2004 to 2024, were analyzed.

Results: In patients with therapy of methotrexate at an average dose of 12.5 mg per week, the incidence of local complications was 7.87%. In patients receiving Leflunomide, complications were detected in 9.29% of cases. In group of patients with Sulfasalazine intake, local complications were detected in 7.73% of cases. The complication rate of 7.01% was determined in group of patients who received Glucocorticoids at an average dose of 7.5 mg (recalculation in Prednisone). 1.87% of complications were observed in patients with intake of genetically engineered biological drugs. The highest incidence of local complications was found in patients with RA who had no therapy (27.27%).

Conclusion: The risk of local complications was 3 or more times higher in group of patients with RA without any treatment. So, TJA in patients with RA without treatment are often accompanied by a high risk of intra- and postoperative complications.

P214

COMPARATIVE ANALYSIS OF PERIPROSTHETIC FRACTURES IN TOTAL HIP ARTHROPLASTY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

E. Naryshkin[1], A. Khramov[1], M. Makarov[1], T. C. Phan[1], A. Rozov[1], S. Maglevaniy[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications due to the presence of an inflammatory process, prolonged intake of glucocorticoids (GC), disease-modifying and genetically engineered biological drugs, reduced physical activity, functional disorders and severe osteoporosis. All this contributes to an increased risk of intraoperative complications, including periprosthetic fractures.
Objective: to conduct a comparative analysis of periprosthetic fractures, which included intraoperative fractures of the large and small trochanter, as well as the acetabulum, during total hip arthroplasty (THA) in patients with RA and osteoarthritis (OA).
Material and methods: 1173 hip replacement operations were performed in patients with RA and OA in the period from 2004 to 2024 (OA – 709, RA – 484).
Results: A total of 41 (3.49%) periprosthetic fractures were diagnosed during THA. Of these:
- 23 (4.96%) fractures occurred in patients with RA;
- 18 (2.54%) in patients with OA.
In most cases, osteosynthesis with intraosseous sutures, circular sutures with wire or plate was performed for the treatment of periprosthetic fractures (61.8%), and Wagner's long revision leg was also used. Osteosynthesis was performed more often in patients with OA (66.7%), less often in patients with RA (43.5%).
Statistical analysis of the data revealed a significantly higher number of complications in the group of RA patients ($p=0.0288$). Significant differences were also obtained in the analysis of each type of complications ($p<0.05$).
Conclusion: obtained results confirmed that the risk of periprosthetic fractures was 2 times higher in RA patients than in patients with OA. Therefore, these patients require a special approach, which includes in the competent medical perioperative treatment of osteoporosis and careful handling of bone and surrounding soft tissues during the operation.

P215

THE PREVALENCE OF RHEUMATOID ARTHRITIS IN ALBANIAN FEMALE PATIENTS WITH LOW BONE MINERAL DENSITY

A. Kollcaku[1], J. Kollcaku[2], A. Shiroka[1], N. Dushaj[1], V. Duraj[1]

[1]Mother Teresa University Hospital Center, Tirana, Albania; [2]Policlinic no.3, Tirana, Albania

Objective: This study aimed to assess the correlation between the prevalence of rheumatoid arthritis and changes in bone mineral density in Albanian females.
Method: In this study, a sample of 2198 women, who presented to the rheumatology outpatient clinic in Tirana, was involved. All of them completed a specific questionnaire for risk factors of osteoporosis, and bone mineral density was measured for each subject by Achilles ultrasound technique, which is specifically used for screening studies.
Results: The prevalence of osteopenia and/or osteoporosis was 36.5% (N=803), while the prevalence of rheumatoid arthritis was 19.9% (N=437). Overall, 298 (13.6%) of females who participated in this study were ≤ 50 years old, compared to 1900 (86.4%) of females who were >50 years old. A model of binary logistic regression was used to evaluate the relation between low bone mineral density and rheumatoid arthritis. Hosmer-Lemeshow test was applied to evaluate the validity of the above model. Statistical analysis was performed by Statistical Package for Social Sciences (SPSS), version 17.0. In the gross model (not adjusted), low bone mineral density was positively associated with rheumatoid arthritis (OR=1.49, 95% CI=1.21-1.85). Prevalence of rheumatoid arthritis was higher in females with low bone mineral density (24%), compared to females with normal bone mineral density (17.5%) (P <0.001).
Conclusions: Rheumatoid Arthritis is an autoimmune disease, which correlates with changes in bone mineral density. A positive relation between RA disease and low bone mineral density was found in Albanian women enrolled in this study.
Keywords: osteoporosis, rheumatoid arthritis
Conflict of interest: none declared

P216

ADJUVANT CHEMOTHERAPY WITH TAXANES CAUSES NO OVARIAN FAILURE NOR OSTEOPENIA IN RATS

A. Kurth[1], A. Müller[2], C. Scheepers[3], P. Hadji[4]

[1]Orthopaedic Institute Dr. Baron&Colleagues and JW Goethe University, Frankfurt, Frankfurt, Germany; [2]Gynecology Practice, Munich, Germany; [3]Orthopaedic Practice, Stuttgart, Germany; [4]Hormon and Osteoporosis Center Frankfurt and Philipps University Marburg, Frankfurt, Germany

Background: The majority of women with breast cancer survive long due to improvements in diagnosis and treatments. Osteoporosis has been identified as a late complication of tumor therapy in breast cancer. The suggested cause of osteopenia/osteoporosis is linked to a negative effect of chemotherapy on the ovarian function, which leads to estrogen deficiency. The purpose of this study was to investigate the effect of Docetaxel chemotherapy (DOC) on ovarian function and bone mass.
Material &Methods: 50 female SD rats were ovariectomized (OVX) or had a sham-ovx (SHAM) at the age of six month. According to the literature, a significant osteopenia develops after 12 weeks after ovx. After 12 weeks group 1 was treated with 6 cycles of DOC in a 3-week interval (SHAM/DOC). The other groups received a placebo treatment (OVX/plac), (SHAM/plac). Bone Mineral Density (mg/cm^2) of the lumbar vertebrae was assessed after 12 weeks after ovx and 12 weeks post chemotherapy by using Hologic QDR 4500 (small-animal mode). At the end of the trial the ovarian function was investigated by taking a vaginal smear test and the serum estrogen level. A histological evaluation of the ovaries was done to determine changes after chemotherapy.
Results: OVX caused a significant decrease in BMD, serum estrogen level and vaginal atrophy. There was no sign of developing an ovarian failure or vaginal atrophy after chemotherapy. The ovarian function was sufficient to ensure hormonal effects in the vagina. The estrogen level was significant higher in the treatment-group (SHAM/DOC) than in the OVX-control-group. Densitometry showed no significant decrease of BMD during the treatment with Docetaxel in the SHAM/ DOC-group.
Conclusion: The present study underlines that a DOC chemotherapy has no negative effect on the ovarian function or on bone mass in hormone competent animals. Further investigations are needed to clarify the relation between chemotherapy and cancer treatment induced bone loss (CTIBL).

P217

COMPARISON OF THE GERMAN DVO FRACTURE RISK THRESHOLDS AND REMS-FRAGILITY SCORE IN THE ASSESSMENT OF THE INDIVIDUAL FRACTURE RISK

A. Kurth[1], J. Baron[2]

[1]Orthopaedic Institute Dr. Baron&Colleagues and JW Goethe University, Frankfurt, Frankfurt, Germany; [2]Orthopaedic Instute Dr. Baron&Colleagues, Frankfurt, Germany

Background: The determination of individual fracture risk and skeletal fragility is becoming increasingly relevant for a timely osteoporosis intervention and treatment. In recent years, different prediction models have been established to determine a probability associated to the risk of MOF or hip fractures including femoral BMD. Among these, the German DVO risk algorithm (developed by the Guideline Group of the German Umbrella Organization of Scientific Osteology Societies) is a step-by-step approach that classifies patients in groups of 3-years fracture risk incidence. The investigation aimed to compare the DVO fracture risk with the REMS-Fragility Score (FS), a dimensionless parameter (1-100) that provides information insight bone quality and skeletal fragility.
Material and Methods: In an observational study we recorded the data of patients who underwent DXA and REMS scans at an Orthopaedic Institute. The collection included DXA- and REMS- measurements at femur / lumbar spine, general patient information, medical and fracture history. Comparison between DVO and REMS-FS was analyzed using a Kruskal-Wallis test and Wilcoxon test.
Results: A total of *n* = 256 patients (128 per anatomical site) were analyzed. FS differed significantly across the DVO 2023 threshold groups (<3%, 3-5%, 5-10%, >10%) at both sites. Median FS increased stepwise with higher DVO thresholds from 14.58 (Q1–Q3: 12.68–21.12) in the < 3% group to 22.92 (19.53–29.94) 3-5% group, 33.38 (25.76–42.57) 5-10% group, and 55.50 (34.73–66.08) in the >10% group at femoral site. Lumbar spine, median FS increased from 24.08 (Q1–Q3: 21.60–28.07) in the < 3% group to 27.26 (23.87–33.38) 3-5% group, 29.98 (24.75–41.66) 5-10% group, and 40.65 (28.54–56.57) in the >10% group. Post-hoc comparisons showed significant differences (p< 0,05) between all group

pairs.
Summary: The results show a good level of agreement between DVO risk algorithm 2023 and REMS-FS, thus further reinforcing the hypothesis that quantitative information of bone fragility plays a crucial role in skeletal fragility and fracture risk. These results also confirm the efficacy of FS in identifying high risk subjects. REMS ultrasound technology appears to be a valuable tool allowing a timely indication for intervention and preventive strategies.

P218

ASSESSMENT OF THE COGNITIVE AND PHYSICAL PROFILE OF PATIENTS ADMITTED TO LONG-TERM CARE AS A VARIABLES OF FALLS RISK

A. L. Coutinho[1], R. Aparecido dos Santos[1], M. Dalke[1], M. Guarda Bastos[1], J. G. Claudino[1], M. Cercal Eduardo[1], O. De Matos[1]

[1]Federal University of Technology - Parana, Curitiba, Brazil

Objective: To evaluate the cognitive and motor impairment of patients institutionalized in long-term care homes as predictive variables of fall risk for this population.
Methods: Twelve patients were evaluated, six male and six female, with a mean age of 81.3 ± 8.7 years and classified as dependency grade I and II in three long-term care facilities for the elderly people, with a stay period of 2 to 36 months. Data on cognitive characteristics were collected through the questionnaire Mini-Mental State Examination (MMSE), while the Tinetti Performance-Oriented Mobility Assessment (POMA) and Short Physical Performance Battery (SPPB) protocols were used to assess balance.
Results: In this first phase, the SPPB protocol was used, but it proved inapplicable to a more vulnerable population. The protocol results showed 05 participants with low scores, 05 were unable to perform, and 02 with moderate scores, indicating the tool's ineffectiveness. Given these limitations, the POMA was subsequently applied to better capture functional mobility and fall risk. According to the POMA, 66.7% of the participants (n=8) were classified as having a high risk of falls (score <19), 16.7% (n=2) presented a moderate risk (score between 19 and 24), and 16.7% (n=2) demonstrated a low risk (score >24). Most older adults (75%) scored <20 on the MMSE, indicating cognitive impairment associated with low education level.
Conclusion: We consider that the degree of dementia with other cognitive changes together with visual difficulties, in general, compromise the understanding and performance of tests. Regardless of the difficulty in applying the tests, the results confirm the real risk of falls for this sample and demonstrate the importance of therapeutic interventions and ergonomic adaptations to minimize the risks of falls and the limitations imposed by them. This reinforcing the need for more sensitive and adaptable assessment tools in frail older populations.

P219

INFLUENCE OF OSTEOARTHRITIS IN PATIENTS WITH LOW BONE MINERAL DENSITY AS A PREDICTOR OF THE RISK OF FALLS IN FRAIL ELDERLY INDIVIDUALS

A. L. Coutinho[1], R. Aparecido dos Santos[1], M. Dalke[1], M. Guarda Bastos[1], J. G. Claudino[1], M. Cercal Eduardo[1], O. De Matos[1]

[1]Federal University of Technology - Parana, Curitiba, Brazil

Objective: The cross-sectional study was based on a first phase of a prospective study to assess the risk of falls and fractures and aims to analyse the influence of osteoarthritis as a predictor of risk of falls in older people with low bone mineral density.
Methods: 151 male and female participants with low bone mineral density were divided in control group (N=49;67.8±4.9yrs) and study group with Osteoarthritis (N=102; 71.1±5.5yrs). Dual energy x-ray absorptiometry (DXA) was used to evaluate Total lean mass (TLM) and bone areas. Handgrip strength (HGS), Short physical performance battery (SPPB), Chair stand test (CST) reach test (RT) and single leg stance (SLS) were also assessed.
Results: Descriptive analysis showed similar values between groups and no statistical differences were found between body composition, only in the SLS performance test. Despite similar results, in all balance tests the group with associated osteoarthritis obtained a lower performance compared to the control group. In the correlation between variables, while the control group did not show correlations between the balance test variables, the study group showed important correlations between all tests, highlighting the reach test and single leg stance. Regarding total lean mass (TLM), which directly influences balance and is related to aging and falls, the study group presented the greatest losses, which may be linked to the higher average age of this group.
Conclusion: Although the research addressed patients with low bone mineral density, it was evident from the large number of patients with osteoarthritis (102 of the total 151 patients evaluated) and their lower performance in balance tests, that the risk of falls can be aggravated by joint impairment, which compromises the entire postural structure and consequently increases not only the risk of falls but also of fractures due to low bone mineral density.

P220

INFLUENCE OF POOR SLEEP QUALITY ON FRAILTY AND INCREASED RISK OF FALLS IN COMMUNITY-DWELLING ELDERLY PEOPLE

A. L. Coutinho[1], R. Aparecido dos Santos[1], M. Dalke[1], M. Guarda Bastos[1], J. G. Claudino[1], M. Cercal Eduardo[1], O. De Matos[1]

[1]Federal University of Technology - Parana, Curitiba, Brazil

Objective: This cross-sectional study was based on a first phase of a prospective study to assess the risk of falls and fractures. It aims to analyse the influence of poor sleep quality on the frailty of elderly outpatients.

Methods: It was investigated 96 male and female participants (69.7±5.9

yrs.), who were divided according to the Pittsburgh sleep quality questionnaire as normal sleep group (NSG, n=50) and poor sleep group (PSG, n=46). Dual energy x-ray absorptiometry (DXA) was used to evaluate total body mass (TBM), total lean mass (TLM) and bone areas. Handgrip strength (HGS), Short physical performance battery (SPPB) and Chair stand test (CST) were also assessed.

Results: The descriptive analysis showed similar values between the groups and no statistical differences were found. For the PSG, the TBM had a 28.3% influence on the Appendicular skeletal mass (ASM/H²) and 8.9% on CST; the TLM had a greater influence than the NSG for the bone density sites, with 28% and 24.2% for Femoral bone mineral density (FBMD) and Lumbar bone mineral density (LBMD), respectively; the ASM/H² also had a greater influence on HGS with 37%.

Conclusion: The results of the comparison between groups of frail elderly individuals with non-restorative sleep and normal sleep, demonstrated that poor sleep appears to negatively affect physical performance variables, as well as lean mass and bone mineral density. Therefore, these multifactorial conditions in older individuals with poor sleep may increase frailty and risk of falls, consequently, fractures in older adults.

P221

ESTABLISHING THE ASSOCIATION BETWEEN THE METHYLATION STATUS OF BMP2 GENE PROMOTER AND THE PATHOGENICITY OF OSTEOPOROSIS

Amal M. Alenad[1,2] , Nahla S. Almushaigih[1], Malak N. Khattak[2], Abdullah M. Alnaami[2], Mohammed G. Ansari[2], Nasser M. Al-Daghri[2], Majed S. Alokail[3]

[1]Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia; [2]Chair for Biomarkers of Chronic Diseases, Department of Biochemistry, College of Science, King Saud University, Riyadh , Saudi Arabia; [3]Protein Research Chair, Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia,, Riyadh , Saudi Arabia

Objectives
Osteoporosis (OP) is the most common metabolic bone disorder, characterized by decreased bone mass and increased fracture risk, particularly in postmenopausal women. Bone remodeling is regulated by osteocytes, osteoblasts, and osteoclasts, whose activities are influenced by genetic and epigenetic factors. DNA methylation, an epigenetic mechanism involving cytosine methylation at CpG islands in gene promoter regions, has been implicated in several human diseases, including OP. Bone morphogenetic protein 2 (BMP2) is a key bone-forming factor that promotes osteoblast differentiation and bone matrix protein expression. This study aimed to determine the methylation status of the BMP2 promoter in women with OP, compare it with healthy controls, and assess the relationship between BMP2 promoter methylation and serum BMP2 levels.
Material and Methods
A total of 51 postmenopausal Saudi female blood samples were analyzed, including 30 patients diagnosed with osteoporosis and 21 age-matched healthy controls. Genomic DNA was extracted and subjected to bisulfite treatment, followed by methylation-sensitive polymerase chain reaction (MS-PCR) to assess methylation patterns at three different regions of the BMP2 promoter. Serum BMP2 concentrations were measured using enzyme-linked immunosorbent assay (ELISA). Statistical analyses were performed to compare methylation status and serum BMP2 levels between groups and to evaluate their association.
Results
The BMP2 promoter was found to be hypomethylated at two distinct regions in patients with osteoporosis compared to healthy controls. This hypomethylation was accompanied by a statistically significant increase in serum BMP2 levels in the OP group. The observed changes suggest an inverse relationship between BMP2 promoter methylation and BMP2 protein expression in osteoporosis.
Conclusion
These findings confirm the essential role of BMP2 in bone remodeling and repair in osteoporosis and demonstrate that its expression correlates with disease severity. Altered methylation of the BMP2 promoter may serve as a potential epigenetic biomarker for early diagnosis of osteoporosis. Furthermore, therapeutic strategies aimed at enhancing BMP2 expression may have long-term protective effects if applied during the osteopenia stage, potentially preventing progression to osteoporosis and reducing fracture risk.
Keywords: Osteoporosis, DNA methylation, Epigenetics, BMP2

AI-ASSISTED OPPORTUNISTIC DETECTION OF VERTEBRAL COMPRESSION FRACTURES IN CT SCANS

Z. Huang[1,2], R. Bleakney[3,4], A. Kamona[3,4], F. Alavi[2], E. V. Navarro[2], Y. Zhang[2], T. Chung[3,4], H.-J. Jang[3,4], A. M. Cheung[1,2,4]

[1]Department of Medicine, University of Toronto, Toronto, Canada; [2]Department of Medicine, University Health Network and Sinai Health System, Toronto, Canada; [3]Department of Medical Imaging, University of Toronto, Toronto, Canada; [4]Joint Department of Medical Imaging, University Health Network and Sinai Health System, Toronto, Canada

BACKGROUND: Vertebral compression fractures (VCFs), a hallmark of osteoporosis, are often asymptomatic. In this study, we evaluated the diagnostic utility of an artificial intelligence (AI) software for the opportunistic detection of VCFs in computed tomography (CT) scans.
METHODS: This dual-center retrospective study was conducted at the University Health Network, Toronto, Canada. Consecutive thoracic, abdominal and spine CT scans, from January 1–10, 2023 and June 1–10, 2024, were analyzed using Nanox.AI software HealthOST V1.1 1.0.2, if the following criteria were met: age 50 years and above, sagittal scans with at least 4 vertebrae between T1-L4, and availability of a radiology report. All eligible scans were also reviewed by two expert musculoskeletal radiologists. The Genant semiquantitative technique was used, with moderate and severe VCFs corresponding to height reductions of 25%-40%, and greater than 40%, respectively. A scan was flagged as positive if at least one moderate or severe VCF was identified. The results from software and the original reports were compared to those of the expert radiologists (gold standard). If both software and experts flagged it as positive, regardless of the vertebral level(s), the sample was considered true positive for overall diagnostic performance.
RESULTS: Of the 638 consecutive CT scans, 504 satisfied the inclusion criteria and were successfully analyzed. AI software identified 113 scans as positive, and 391 scans as negative for moderate or severe VCFs. Radiologists excluded 11 scans, and validated 493 scans (17 spine, 164

chest, 188 abdomen/pelvis and 124 chest/abdomen/pelvis). The mean age was 69.9 years (SD 11.2), with 47.9% females. The prevalence was 18% by our expert radiologists. The overall sensitivities and specificities of the software were 90% (95%CI: 82%-95%) and 93% (95%CI: 90%-95%) [PPV of 74% (95%CI: 67%-81%) and NPV of 98% (95%CI: 96%-99%)], while those of the original reports were 49% (95%CI 38%-60%) and 99% (95%CI: 97%-100%), respectively. The sensitivities of the AI software at vertebral levels are shown below.
CONCLUSIONS: AI software can enhance the sensitivity of opportunistic detection of moderate and severe VCFs in thoracic, abdominal and spine CT scans, potentially helping radiologists improve reporting accuracy.

P223

ANALYTICAL IMPACT OF METHOD-DEPENDENT VARIABILITY IN BONE ALKALINE PHOSPHATASE IMMUNOASSAYS

A. Mackowiak[1], P. Lukas[2], A. Bouquegneau[3], P. Delanaye[3], E. Cavalier[1,2]

[1]Clinical Chemistry, Center for Interdisciplinary Research on Medicines (CIRM), University of Liège., Liège, Belgium; [2]Department of Clinical Chemistry, University Hospital of Liège, Liège, Belgium; [3]Department of Nephrology, Dialysis and Transplantation, University of Liège, Liège, Belgium

Objective: This study compared the analytical performance and clinical agreement of four bone-specific alkaline phosphatase (bALP) immunoassays across distinct patient subgroups, as the availability of multiple commercial assays may lead to discrepancies in patient results.
Material and methods: Remnant serum samples from 140 subjects (20 non-CKD controls, 80 CKD patients stratified by GFR, 20 haemodialysed patients, and 20 kidney-transplanted patients) were analysed using IDS BAP® EIA, IDS-iSYS Ostase®, Access Ostase® and Liaison XL Ostase®. Results are expressed in µg/L. Samples were also analysed using Hydrasis ISO-PAL 15 electrophoresis, to quantify bone- and liver-specific ALP fractions. Associations were assessed using Spearman's correlation and agreement was evaluated using Bland–Altman analysis. Absolute and logarithmic differences were used to assess constant and proportional bias, respectively. Differences across clinical subgroups were tested using Kruskal–Wallis's test.
Results: Significant correlations were observed for all assay pairs (Spearman's ρ = 0.816–0.984). However, Bland–Altman analyses revealed systematic differences between methods. The widest limits of agreement and largest biases were observed in comparisons involving the Liaison XL assay. Healthy controls showed limited dispersion and low bias, whereas CKD and dialysis patients exhibited increased dispersion, particularly for assay pairs involving Liaison XL. Both constant and proportional biases differed significantly across patient subgroups for selected assay pairs, indicating a population-dependent effect on assay agreement ($p < 0.05$). Proportional biases ranged from 3.96% to 90.69%, depending on the assay pair and patient population. All immunoassays correlated with bALP fraction (Spearman's ρ = 0.590–0.693). However, visual inspection of comparison graphs showed that samples deviating from the expected correlation were associated with higher liver-specific ALP fractions.
Conclusion: Despite correlations between bALP immunoassays, significant biases were observed, indicating limited interchangeability between methods. These discrepancies were amplified in CKD and dialysed populations, underscoring the need for careful clinical interpretation, particularly for patient follow-up, and reinforcing the importance of assay harmonisation and standardisation.

P224

SHOULD A SURGERY BE PERFORMED FOR CERVICO OSTEOARTHRITIC MYELOPATHIES DECOMPENSATED BY TRAUMA TO THE CERVICAL SPINE: ABOUT 37 CASES

A. Mahtout[1]

[1]Blida regional university military hospital, Blida, Algeria

The incidence of the spinal cord trauma (SCT) in Algeria is 20 people/1000 inhabitants. SCT can lead to spinal cord injury with out bone involvement, particularly when a narrow cervical canal (NCC) preexists. 75% of people over 65 have a narrow cervical canal, which is the most common risk factor for spinal cord injury. Furthermore, the cervical cord is more vulnerable because it is less well vascularized, particularly in the elderly population.
We report the experience of the neurosurgery department in the care of 37 patients with cervico osteoarthritic myelopathies whose ages are between 56-78 years old and who are victims of various accidents manifested by incomplete tetraplegia evaluated by the score by JOA. Our course of action was: hospitalization of patients; implementation of a therapeutic regimen based on corticoids 2 mg/kg/d associated with adjuvant treatment; the wearing of a cervical collar and not a minerva given the absence of spinal instability; and nursing, Reassessment of the JOA score on D3 post-trauma then patient discharge. Patients systematically reviewed in spine consultation at 1 month with a reassessment of the JOA.
The neurological and functional benefit of decompressive and stabilization surgery remains controversial. In our study, early surgery did not improve neurological and functional recovery and was not associated with fewer medical complications or shorter hospital stay. Moreover, there is no evidence in the literature to encourage routine early surgery in patients with SCT on NCC with out vertebral fracture. In addition, potential preoperative complications must be taken into account, particularly in the elderly population. In the acute phase, the most frequent indications for surgery are the presence of signs of clinical and/or radiological instability. The criteria traditionally used in favor of remote surgery are worsening or stagnation of a neurological state after a phase of improvement.

P225

PLACE OF CURRENT IMPLANTS IN THE MANAGEMENT OF CERVICO OSTEOARTHRITIC MYELOPATHY (COM) ABOUT 150 CASES

A. Mahtout[1]

[1]Blida regional university military hospital, Blida, Algeria

Objective: Cervic osteoarthritic myelopathy is a cervical spinal cord suffering associating a narrowing of the dimensions of the cervical canal of osteoarthritis origin, the natural evolution of the pathology is towards progressive aggravation until tetraplegia. At present there is no medical treatment, so it is an almost exclusively surgical treatment that both decompresses the cervical spinal cord.
Case report: We report a series of 150 cases collected in the neurosurgery department, carrying CAM at the operative stage and having benefited from decompression with the addition of prosthetic material, namely cervical prostheses. The whole difficulty of the management of CAM is to pose an indication for surgery at the right time, the addition of implants in this surgery has al lowed on the one hand to restore spinal biomechanics but also to restore a function of lost neck mobility.
Conclusion: We are convinced that although the cost of acquisition is relatively high, the addition of cervical prostheses allows a restoration of function and a social and professional reintegration of patients

P226

OS ODENTOIDEUM ABOUT 03 CASES

A. Mahtout[1]

[1]Blida regional university military hospital, Blida, Algeria

Objective: Bone odentoidum or mobile odontoid process is one of the malformations of the cervico-occipital hinge. It is about a defect of union of the center of ossification of the odontoid on the body of the axis. The malformation exposes you to atlo-axoid instability and the risk of bulbo-medullary compression.
Methods: We report the observation of 03 active men whose age varied between 18-247 years with a notion of craniocervical trauma and who presented progressively in 2 years persistent cervical pain and stiffness with heaviness of the four limbs with discreet sphincter disorders.
Results: The clinical examination objectified spastic tetraparesis with associated sensory disturbances Lateral flexion and extension radiographs can provide useful information about C1-C2 in stability. Computed tomography (CT or simple) is useful to define bony relationships at the base of the skull, C1 and C2. The de gree of C1-C2 instability identified on cervical radiographs is not correlated with the presence of myelopathy. A sagittal diameter of the spinal canal at the C1-C2 level of.13 mm correlates with the myelopathy detected on clinical examination. MRI can show spinal cord compression and signal changes in the cord that cor relate with the presence of myelopathy. To behave given the clinical examination, the patients show signs of deficit associated with imaging objectifying a compression of the bulb, a surgical indication is posed, the intervention consisted of an occipital cra niectomy opening of the occipital foramen and the posterior arc of C1 followed by C3 occiput osteosynthesis using polyaxial rods and screws.
Conclusion: The mobile odontoid process or os odontoideum is a rare anomaly of the cervico-occipital hinge for which we will recall the clinical, radiological, etiological and prognostic aspects for an adequate management. Clinical examination revealed spastic tet raparesis with associated sensory disturbances. Cervical CT and MRI confirmed the odontoid-axoid dislocation, the CT on the one hand revealing a corticalized ovoid ossicle in place of the odontoid and the MRI on the other hand the myelomalacia. The therapeutic result was conclusive after surgical approach by posterior approach. The os odontoideum designates a small bone in a position cranial to the axis and independent of the odontoid. The em bryonic, vascular or even traumatic origin are evoked to explain the pathogenesis. It can be discovered incidentally in asymptomatic patients or cause sudden death without the diagnosis being recognized. If symptomatic, the age of discovery is variable and the clinical signs are upper neck pain, neck stiffness, torticollis, spinal cord or cervical radicular compression syndrome without any notion of recent spinal cord injury. Standard radiographs, bet ter cervico-occipital CT, show a rounded or ovoid ossicle, separated from the base of the odontoid and corticalized, unlike recent fractures of the odontoid. MRI shows the repercussions on the bulbo-medullary junction. The approach of choice is the posterior approach to decompress the nervous structures and stabilize the spine. Functional rehabilitation is essential. In asymptomatic subjects, prophylactic surgery is discussed after dynamic X-rays.

P227

CERVICAL SPINAL INJURY SECONDARY TO A SPORTS ACCIDENT ABOUT 29 CASES

A. Mahtout[1]

[1]Blida regional university military hospital, Blida, Algeria

Objective : Trauma to the cervical spine can be differentiated from a therapeutic point of view, in two situations: The unstable spine (fracture + ligament rupture) where the potential neurological risk, medullary or radicular, guides in a completely hierarchical and validated way the conduct to be held on the ground and then at a distance. The microtraumatic spine where, as we know, the frequency of 'common' spinal pain, and the functional, socio-professional and athletic repercussions, which vary greatly from one patient to another for the same lesion, involve more diagnostic and therapeutic pathways. individualized and, for the majority, primarily or even solely conservative.
Methods: We report a series of 29 patients admitted as part of the emergency at the level of the neurosurgery department/central hospital of the army and treated surgically in emergency fol lowing various sports accidents. all the difficulty of management is based on the right indication:- Should a great sportsman be operated on or not?- If so, what is the benefit?- And above all can he resume his sporting activity of competition?
Results: Of the 29 athletes who had spinal cervical lesions with out medullary, 21 were indicated for surgery: - 07 patients operated by an anterior approach with dissectomy followed by placement of a cervical cage and anterior osteosynthesis on one level.- 04 patients via the posterior route due to articular collisions, having benefited from fixation via the posterior route.08 patients when to them were of orthopedic indication with installation of a cervical collar with a rigorous clinical radio control.
Conclusion: The surgical indication is always posed in front of spinal instability, this must be discussed at length and with the consent of the patient in athletes. orthopedic treatment is indi cated when the elements of spinal stability are not compromised, otherwise surgery is the only therapeutic recours. The management of high-level athletes requires in-depth compression of the lesion mechanisms, careful reading of

radiological images and multidisciplinary management. not only surgical but functional and rheumatological rehabilitation.

P228

COGNITIVE STATUS MODULATES THE PROTECTIVE EFFECT OF COHABITING CAREGIVERS ON FALL-RELATED FRACTURES IN OLDER ADULTS

A. Medioli[1], Z. Kupa[1], J. Serafini[1], A. Asseborn[1], C. Cucchetti[1], K. Barbarino[1], N. Loubadi[1], C. Giuseppe[1]

[1]Hospital, Clinica Sant'Antonino, Piacenza, Italy

Objective(s)
To assess the association between cohabiting caregiver presence and the incidence of falls and fractures in older adults, and to determine whether comorbidity burden and cognitive status modify this relationship.

Material and Methods
An observational study was conducted including 313 older adults. Falls and fractures were recorded during follow-up. Caregiver status (cohabiting vs non-cohabiting) was assessed during the geriatric multidimensional assessment. Comorbidity burden was evaluated using the Charlson Comorbidity Index (CCI), and cognitive function using the Mini-Mental State Examination (MMSE). Patients were stratified by CCI (0–1 vs 2–6) and MMSE (>27 vs <27). Group comparisons were performed using the chi-square test.

Results
Overall, 160 patients (51.1%) experienced at least one fall and 126 (40.3%) sustained a fracture.Cohabiting caregiver presence was associated with a lower, but non-significant, incidence of falls compared with patients without a caregiver (47.9% vs 53.9%; p = 0.29), while fracture incidence was comparable between groups (39.0% vs 41.3%; p = 0.71).Stratification by comorbidity burden did not reveal statistically significant differences in fall-related fractures to caregiver presence in either low-risk (CCI 0–1: 33.3% vs 55.6%; p = 0.50) or high-risk patients (CCI 2–6: 47.6% vs 53.8%; p = 0.27), although a consistent trend toward fewer falls was observed among high-risk patients with a caregiver.

In contrast, cognitive status strongly modified the association between caregiver presence and falls related fractures. Among patients with preserved cognitive function (MMSE >27), the incidence of falls was markedly lower in those with a cohabiting caregiver compared with those without (12.5% vs 60.0%; p ≈ 0.02). No protective effect of caregiver presence was observed in patients with cognitive impairment (MMSE <27:40.0% vs 42.6%; p = 0.65).

Conclusion(s)
Cohabiting caregiver presence was not associated with a global reduction in related fractures, However, cognitive status emerged as a key determinant of caregiver effectiveness, with a significant protective effect observed only in cognitively preserved patients. These findings suggest that caregiver-based fall prevention strategies should be tailored according to cognitive status and that additional targeted interventions are required for cognitively impaired individuals.

P229

SARCOPENIA – NATURAL PART OF AGING?

A. Miceva-Trajkova[1], G. Andonov[1], M. Miceva[2]

[1]JZU Opsta bolnica Strumica, Strumica, North Macedonia; [2]PZU Dr. Micev, Strumica, North Macedonia

A.Miceva –Trajkova 1, G.Andonov 2, M. Miceva 3
1,2 General Hospital-Strumica, North Macedonia 3 PZU Dr. Micev-Strumica, North Macedonia
Sarcopenia – natural part of aging ?
Sarcopenia – progressive loss of muscle mass and function, that occurs as a natural part of aging. It affects about five to thirteen people, ages 60 to 70, up to 50% of people who are 80 or older. It is characterized by a decline in skeletal muscle mass, strength and physical performance in older adults associated with reduced quality of life, increased risk of requiring long term care, a significant economic burden, on both patients and their families.
It is not a surprise that loss of muscle mass has many downsides. It is closely linked with a greater incidence of falls and makes you more likely to brake a bone. Also, it can put you at risk for post-operative complications, longer hospital stays, linked with metabolic disorders, cognitive impairment and mortality. Both men and women start losing muscle mass as they get older. It's a gradual decline of about 3-5% each decade, starting at age 30.

Causes
• decreased protein synthesis
• hormonal changes
• nervous system changes
• lack of exercise
• being overweigh or obese
• chronic illness
• nutrient deficiencies.

Early signs of sarcopenia
• muscle weakness
• increased fatigue
• decreased physical activity
• thinner limbs
• slower walking speed

Advanced sarcopenia symptoms
• difficulty with daily activities
• poor balance of falling
• need cane or walker
• loss of independence
• more visible muscle wasting
• poor posture

Sarcopenia prevention
• increased protein intake
• include vitamin D in diet
• eat nutritious foods

• engage in strength training

• regular aerobic exercise

Whether you're 50 or 90, it is important to stay on top of your health and well being. Everyone experiences some amount of muscle loss as they age, but with sarcopenia, it happens much faster. It maybe time to begin treatment for sarcopenia if there are any of the above mentioned signs. There are ways to treat and even reverse the effects of the condition. If you've experienced muscle weakness or any other symptom of sarcopenia, call your healthcare institution to diagnose the condition and develop a personal treatment plan.

P230
FIBROMYALGIA

A. Micev-Trajkova[1], G.Andonov[2], M. Miceva[3], G. Trajkov[4], E.Vankoska[5]

[1,2] General Hospital-Strumica, North Macedonia, [3] PZU Dr. Micev-Strumica, North Macedonia, [4] DKC Karposh-Skopje, North Macedonia, [5] Nextsense-Skopje, North Macedonia

Fibromyalgia – chronic widespread pain
Fibromyalgia involves widespread body pain and it is a long term condition. The pain happens along with fatigue. It can involve issues with sleep, memory and mood. It affects the way the brain and spinal cord process painful and non-painful signals, so sensitivity to pain increases. Fibromyalgia has no medical sign. Symptoms often start after a triggering event that include injuries, surgery, infections or emotional stress. Women are more affected than men.
Patients have:

• Headaches

• pain due to temporomandibular joint disorders

• anxiety

• depression

• irritable bowel syndrome.

Patients may also have endometriosis, interstitial cystitis. The causes vary from person to person. It is thought that a combination of genetic and environmental factors are involved, but genetics alone is not enough. Patients have changes in the way the central nervous system processes pain messages. Patients with fibromyalgia have a chemical imbalance with low levels of serotonin, noradrenaline and dopamine in the brain. These hormones are important in processing pain messages from different parts of the body and in regulating mood, appetite, sleep, behavior and stress responses.

Fibromyalgia tends to run in families and there is usually a trigger for it – stressful or traumatic event. The most common symptoms are pain and morning stiffness all over the body, sensitivity of the skin and muscles to touch and pressure. Fatigue, anxiety, sleep problems, tension headaches. Fibromyalgia is difficult to treat, there is no cure. Treatment, medication, lifestyle changes and complementary therapies are aimed at reliving symptoms, improving quality of life and daily functioning. Physical activities – aerobic exercise, walking, cycling, swimming, stretching exercises are recommended. People are less tired, in a better mood, function better and their quality of life improves.
Fibromyalgia is estimated to affect 1.8% of the population. Weight management is helpful for reducing fibromyalgia impact. Several forms of electrical neuromodulation improve functioning. Fibromyalgia causes a substantial economic and societal burden, due to disability and reduced work hours.

P231
MEDIUM TERM REAL WORLD OUTCOMES AND SAFETY OF INTRA ARTICULAR POLYACRYLAMIDE HYDROGEL INJECTION FOR KNEE OSTEOARTHRITIS

A. Miller[1], Z. Azeez[1], N. Mansour[1], E. Blain[2], J. Potter[1]

[1]Grange University Hospital, Newport, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom

Objective
Knee osteoarthritis (OA) is a prevalent cause of pain and functional limitation, with synovial inflammation playing a central role in symptom generation and disease progression. Durable nonsurgical treatment options remain limited. This study aimed to evaluate mediumterm clinical outcomes, patient satisfaction, and safety following intraarticular injection of a nondegradable polyacrylamide hydrogel for symptomatic knee OA in realworld clinical practice.
Material and Methods
A prospective observational study was conducted in a tertiary orthopaedic setting. All patients received a single 6 mL intraarticular injection of a polyacrylamide hydrogel according to standardised procedural guidance. Outcome measures were collected at baseline and at 12 and 52 weeks postinjection. Primary outcomes included visual analogue scale (VAS) pain score and WOMAC pain and total scores. Treatment response was assessed using OARSI responder criteria. Patients were enrolled into structured remote followup and completed an anonymous satisfaction questionnaire. Adverse events and subsequent interventions were recorded.
Results
A total of 316 patients were treated, with 116 patients providing complete 52week outcome data (age range 41–89 years; Kellgren–Lawrence grade 2–4). Statistically significant improvements were observed at 12 and 52 weeks compared with baseline for VAS pain (67 vs 43 vs 46; $p < 0.0001$), WOMAC pain (59 vs 36 vs 41; $p < 0.0001$), and WOMAC total score (60 vs 39 vs 40; $p < 0.0001$). Eightyfour percent of patients met OARSI responder criteria at one year. Ninetyfive patients completed an unselected satisfaction survey, with 68% indicating they would recommend the treatment and 62% reporting overall satisfaction. Adverse events were uncommon (<1%). Three patients experienced postinjection inflammatory reactions, including one requiring arthroscopic washout; all microbiological investigations were negative.
Conclusion
Intraarticular polyacrylamide hydrogel injection was associated with significant and sustained improvements in pain and function at one year, with a low complication rate in routine clinical practice. These findings support its use as a jointpreserving nonsurgical treatment option for selected patients with symptomatic knee osteoarthritis.

P232

PREVALENCE OF OSTEOPOROSIS IN POST LIVER TRANSPLANT PATIENTS

K. Rupwane[1], A. Alok[1], S. Saigal[1], A. Mithal[1]

[1]MAX SUPER SPECIALITY HOSPITAL SAKET NEW DELHI, NEW DELHI, India

Objective
This study aimed to determine the prevalence of osteoporosis in post-liver transplant patients and to evaluate the relationship between bone mineral density (BMD) with various variables.

Material and Methods
This cross-sectional observational study was conducted at Max Super Speciality Hospital, New Delhi. Adults (≥18 years) who had completed at least six months after liver transplantation were included. Bone mineral density was assessed by dual-energy X-ray absorptiometry. Biochemical evaluation included renal and liver function tests, serum calcium, phosphate, 25 OH Vit D, intact parathyroid hormone, bone turnover markers (P1NP, β-CTX), serum testosterone in males, estradiol in females, glycosylated hemoglobin, and thyroid function tests. Duration of exposure to corticosteroids, tacrolimus, and mycophenolate was recorded. Correlation analysis was performed using Pearson's coefficient.

Results
A total of 95 patients were included in the final analysis. Osteoporosis was observed in 32.6% of patients, while 32.6% had osteopenia, indicating that nearly two-thirds of the cohort had low bone mass. BMD demonstrated a significant inverse correlation with duration since transplantation at the lumbar spine, neck of femur (NOF), and total hip. Duration of corticosteroid therapy showed significant negative correlations with BMD at the spine ($r = -0.214$, $p = 0.0369$), NOF ($r = -0.351$, $p = 0.0005$), and total hip ($r = -0.322$, $p = 0.0014$). Similarly, tacrolimus exposure was inversely correlated with BMD at the spine ($r = -0.243$, $p = 0.0177$), NOF ($r = -0.343$, $p = 0.0007$), and total hip ($r = -0.334$, $p = 0.001$). Mycophenolate exposure demonstrated weaker associations, with non-significant correlation at the spine but significant inverse correlations at the NOF ($r = -0.232$, $p = 0.0239$) and total hip ($r = -0.215$, $p = 0.0362$). Radiographic vertebral fractures were detected in 11.6% of patients.

Conclusion
Osteoporosis and osteopenia are highly prevalent after liver transplantation. Prolonged immunosuppression, pre-existing liver pathology, longer post-transplant duration, hepatic osteodystrophy and hypogonadism are important determinants of bone loss. Routine assessment of bone health and gonadal status, with early preventive strategies, is essential to reduce fracture risk in this population.

P233

POLYACRYLAMIDE HYDROGEL AS AN INJECTABLE SYNOVIAL IMPLANT: EVIDENCE AND OPPORTUNITY IN KNEE OSTEOARTHRITIS MANAGEMENT

A. Mobasheri[1,2,3,4]

[1]Research Unit of Health Sciences and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland, Oulu, Finland; [2]Department of Regenerative Medicine, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, Vilnius, Lithuania; [3]Department of Joint Surgery, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [4]World Health Organization Collaborating Center for Epidemiology of Musculoskeletal Conditions and Ageing, Liège, Belgium

Objectives 2.5% injectable polyacrylamide hydrogel (2.5% iPAAG) acts as a synovial implant that integrates into the joint lining, restoring elasticity and reducing mechanical stress. This abstract summarizes evidence supporting 2.5% iPAAG as a long-term treatment for knee osteoarthritis, including mechanism of action, histological integration, safety, and clinical outcomes from randomized and observational studies.

Methods Evidence includes histopathology showing synovial integration, biomechanical modelling, long-term observational data, and prospective trials:
ROSA: RCT comparing 2.5% iPAAG (N=119) vs HA (N=120) over 1 year, with a 5-year iPAAG extension (58 completers).

LUNA: Prospective cohort (N=199) with 12-month data.

All WOMAC normalized to a 100-point scale.

Results Animal histology demonstrates stable synovial integration of 2.5% iPAAG with minimal inflammation up to 24 months, with connective fibres anchoring the hydrogel. Modelling shows reduced synovial stress, supported by an equine OA model where 2.5% iPAAG restored synovial elasticity to healthy levels.
In ROSA, 2.5% iPAAG showed non-inferiority to HA at Week 26 for WOMAC pain (LS mean change −18.5 vs −14.8; difference 3.7 [95% CI −0.8; 8.1]), with a similar trend at Week 52. Long-term 2.5% iPAAG extension data showed sustained benefit at 5 years (pain −16.2; stiffness −12.7; function −11.4; all $p<0.0001$). No serious device-related AEs occurred.

In LUNA, 12-month LS mean improvements were 17.0 (pain), 18.5 (stiffness), and 18.8 (function), all $p<0.0001$ vs baseline, with no serious device-related events.

Both studies confirm durable symptom relief and a favourable safety profile, findings that are further supported by long-term observational data and registry experience showing that 2.5% iPAAG remains safe for up to 10 years post-injection, including in patients who subsequently undergo knee replacement.

Conclusions 2.5% iPAAG functions as an implant within the synovial membrane and demonstrates clinically meaningful benefits in the knee joint. Evidence from open-label studies indicate that its therapeutic effect can be sustained for up to five years. Furthermore, long-term follow-up data support the safety of 2.5% iPAAG, with observations extending up to ten years after injection, including in patients who later required knee replacement.

P234

ASSESSMENT AND REAUDIT OF FRAX RISK ASSESSMENT FOR PATIENTS WITH RHEUMATOID ARTHRITIS SEEN IN RCHT OUTPATIENT GENERAL RHEUMATOLOGY CLINICS

H. L. Liaqat[1], A. N. Nasserfarahmand[1], A. P. Pothecary[1], D. H. Hutchinson[1]

[1]Royal Cornwall Hospital, Truro, United Kingdom

This report presents the full audit and reaudit cycle evaluating adherence to NICE and NOGG standards for fracture risk assessment (FRAX) in patients with rheumatoid arthritis (RA) attending RCHT general Rheumatology clinics. Baseline audit (2024) of 105 patients demonstrated very low FRAX documentation (3/105, 2.9%), low DEXA documentation (11/105, 10.5%), and limited evidence of osteoporosis treatment (13 patients). Following introduction of a standardised FRAXbased assessment pathway, the prospective reaudit (2025) of 109 patients demonstrated 100% FRAX completion (109/109), increased DEXA requesting (70/109, 64.2%), and osteoporosis treatment present/initiated in 82 patients. This confirms a closedloop improvement with full compliance achieved for FRAX documentation.

Background

Rheumatoid arthritis is a recognised independent risk factor for osteoporosis and fragility fractures. National guidance (NICE/NOGG) recommends routine fracture risk assessment using FRAX in adults aged 50 years and over, with bone mineral density (DEXA) scanning or treatment where indicated. The 2024 baseline audit at RCHT Rheumatology Department identified missed opportunities for proactive risk assessment and prevention, prompting pathway redesign to embed FRAX into routine care.

Aim

To evaluate compliance with NICE/NOGG fracture risk assessment standards in RA patients and assess the impact of a standardised FRAXbased pathway.

Objectives

1. Determine the proportion of RA patients with documented FRAX risk assessment.
2. Evaluate DEXA scanning where indicated by FRAX or clinical risk factors.
3. Assess osteoporosis treatment initiation where indicated.
4. Complete a reaudit to confirm improvement and close the audit loop.

Method

Baseline Audit (2024): Retrospective review of at least 100 consecutive ≥ 50-year-old RA patients seen in general rheumatology clinics from May to September 2024 based on the data obtained from RADAR platform and summarized in the Excel spreadsheet. Data items: age, FRAX documentation, DEXA documentation, osteoporosis treatment. Reaudit (2025): Prospective review after implementing the FRAX pathway. Data items: FRAX major and hip risks, NOGG risk category, DEXA referral and outcomes, pharmacological treatment, and followup plan.

Results

Baseline (2024): 105 patients; FRAX documented in 3/105 (2.9%); DEXA documented in 11/105 (10.5%); DEXA without FRAX in 8; patients on/with osteoporosis treatment noted: 13. Age median 72.0 years (range 50–91); ≥65 years: 74 (~70.5%).

Reaudit (2025): 109 patients; FRAX documented in 109/109 (100.0%); DEXA requested in 70/109 (64.2%); osteoporosis treatment present/initiated in 82 patients.

Baseline vs Reaudit comparison:

Measure Baseline (n/N, %) Reaudit (n/N, %) Absolute Δ (pp)

FRAX documented 3/105 (2.9%) 109/109 (100.0%) 97.1

DEXA

requested/documented 11/105 (10.5%) 70/109 (64.2%) 53.7

Patients on/started

osteoporosis treatment 13/105 (12.4%) 82/109 (75.2%) 62.8

Conclusions

The introduction of a structured FRAX pathway achieved full compliance with national standards for FRAX documentation and substantially improved downstream investigation and management. The findings close the audit loop and support continued use of the pathway with periodic reaudit to ensure sustainability.

Recommendations

· Maintain mandatory FRAX assessment for all adults with RA (≥50 years) at each clinic review.

· Apply NOGG thresholds to guide DEXA requests and treatment decisions; document DEXA outcomes with Tscores and FRAXwithBMD where available.

· Ensure timely initiation (or optimisation) of osteoporosis therapy for high/very high risk patients or where DEXA is unsuitable.

· Provide continuing education and brief prompts in clinic systems to preserve 100% FRAX compliance.

P235

THE EFFECTS OF DELAY IN TIME TO SURGERY OF HIP FRACTURES PATIENTS IN A DISTRICT HOSPITAL IN UNITED KINGDOM

A. Naraen[1], P. Srinivasan[1], M. Tarique[1], C. Grindley[1]

[1]Deapartment of Trauma and Orthopaedics, Mersey and West Lancashire Teaching Hospitals NHS Trust, Prescot, United Kingdom

Aims

In this study we set about to investigate whether extra theatre time helps in the reduction of time to surgery which inturn improves patient outcome after fracture of neck of femur.

Introduction

Whiston Hospital, part of the Mersey and West Lancashire Teaching Hospitals NHS Trusts, treats about 50 to 55 Hip fracture patients per month during the winter season. Some of the patients come with co-morbidities while others develop new problems or suffer exacerbation of the pre-admission medical issues during their stay in the hospital. After creating an extra session of trauma theatre we wanted to see if these could be better controlled.

Methodology

The Ward Manager and Ortho-geriatric registrar reviewed the medical records of the list of patients who were admitted in December 2023-January 2024 and then those admitted in December 2024 -January 2025 to identify any changes in the incidence of new complications developing in these patients after the Trauma theatre operating time was extended into the evening, under the same operating surgeon to reduce time to surgery.

Results

Prior to the extended evening trauma list there were 104 hip fracture patients were admitted in the winter months 0f December 2023/Jamuary 2024. 28.8% patients underwent surgery after 36 hours of admission. Of those whose whose surgery was delayed beyond 36 hours, 63.75% developed post op complications.

In the group that was seen after the extended evening list was created, during the winter months of December 2024/January 2025, 94 hip fracture patients were admitted. Time to surgery was more than 36 hours in 27.8% patients. Of those whose time to surgery was more than 36 hours, 38.05% developed complications.
Complications ranged from lower limb cellulitis, constipation to hospital acquired pneumonia, acute kidney amongst others.
Some patients were having to starve longer periods due to extended theatre time. patients on evening list could get cancelled due to comorbidities.
Conclusion
We did not observe any significant reduction in time to surgery with introduction of evening theatre list. The post-operation complications were noted to have significantly reduced. Hip fracture patients require early time to surgery to improve the risk of post operation complications leading to better outcomes. This will require well organised hip fracture management team working through the time of admission till the date of discharge. of hip fracture patients

P236

NEUROVISCERAL DYSFUNCTION AND CHRONIC PAIN IN RHEUMATOID ARTHRITIS: IMPLICATIONS FOR BONE LOSS AND OSTEOPOROSIS RISK

A. Nistor[1], E. Russu[1], E. Deseatnicova[1], L. Groppa[1]

[1]Nicolae Testemițanu State University of Medicine and Pharmacy, Chisinau, Moldova

Objectives:
To evaluate the neurovisceral impact of chronic pain in patients with rheumatoid arthritis (RA) and to explore the relationship between pain severity, disease activity, autonomic dysfunction and bone mineral density (BMD), as markers of secondary osteoporosis risk.
Material and Methods:
A cross-sectional observational study was conducted in 34 patients with rheumatoid arthritis, diagnosed according to ACR/EULAR 2010 criteria. The study group included 26 women (76.5%) and 8 men (23.5%), with a mean age of 52.6 ± 9.8 years and mean disease duration of 7.4 ± 4.1 years.
Pain intensity was assessed using the Visual Analog Scale (VAS), disease activity by DAS28-CRP, and autonomic dysfunction by the COMPASS-31 questionnaire. Neurovisceral manifestations were evaluated clinically, including functional gastrointestinal symptoms, autonomic cardiovascular disturbances, fatigue and sleep disorders.
Bone status was assessed by dual-energy X-ray absorptiometry (DXA) at the lumbar spine (L1-L4) and femoral neck. Osteopenia and osteoporosis were defined according to WHO criteria. Correlation analyses were performed between pain intensity, inflammatory activity, autonomic dysfunction scores and BMD values.
Results:
Moderate-to-severe chronic pain (VAS ≥50 mm) was present in 21 patients (61.8%). Patients with severe pain exhibited significantly higher COMPASS-31 scores compared with those with mild pain (38.4 ± 9.6 vs 21.7 ± 8.3, p<0.01), indicating pronounced autonomic dysfunction.
DXA evaluation revealed reduced BMD in 19 patients (55.9%), including osteopenia in 13 (38.2%) and osteoporosis in 6 (17.6%). Patients with low BMD demonstrated higher disease activity (DAS28-CRP 4.6 ± 0.8 vs 3.7 ± 0.6, p=0.01), higher pain intensity (VAS 62.1 ± 14.3 vs 45.8 ± 12.6, p=0.02) and higher COMPASS-31 scores (41.2 ± 8.9 vs 26.4 ± 9.1, p<0.01).
COMPASS-31 scores correlated positively with VAS (r=0.57, p=0.002) and DAS28-CRP (r=0.42, p=0.01), and negatively with lumbar spine BMD (r=-0.39, p=0.02), suggesting an association between autonomic dysfunction, inflammatory burden and bone loss.
Conclusions:
Chronic pain in rheumatoid arthritis is associated with significant neurovisceral and autonomic dysfunction, higher inflammatory activity and reduced bone mineral density. The interplay between persistent pain, autonomic imbalance and systemic inflammation may represent an important pathway contributing to secondary osteoporosis in RA. Incorporating neurovegetative assessment and DXA evaluation into routine management of RA patients with chronic pain may improve early identification of individuals at increased risk for bone loss and skeletal fragility.

P237

DOUBLE TROUBLE: TWO INCOMPLETE ATYPICAL FEMORAL FRACTURES IN A SINGLE FEMUR

A. O'Hanlon[1], K. Mcsherry[1], F. Brennan[1], P. Nolan[2], M. Alamin[2], D. Fitzpatrick[1], R. Lannon[1], A. Hughes[2], K. Mccarroll[1]

[1]Mercers Institute for Successful Aging, St James Hospital, Dublin, Ireland; [2]Department of Orthopaedics, St James Hospital, Dublin, Ireland

Objective:
Atypical femoral fractures (AFF) are well described in patients on bishosphonate therapy with an incidence of up to 1 in 1000 after longterm treatment. In over 30% of cases, they are bilateral with incomplete AFFs frequently identified contalateral to complete AFF. [1] However, multiple incomplete AFFs in the same femur are very rare.
Method:
We report on a patient who presented with a complete AFF and found to have two incomplete AFFs in the contralateral femur.
Results:
A 78-year-old Caucasian woman presented to the emergency department after falling on her left hip. Radiographs revealed a complete subtrochanteric AFF of the left femur and two incomplete AFFs in the contralateral right femur. She had a diagnosis of osteoporosis treated with alendronate for eight years and reported one month of prodromal right hip pain. Apart from smoking and menopause, she had no other risk factors for osteoporosis. Her left AFF was surgically treated with a long, locked cephalomedullary nail and bisphosphonate therapy was discontinued. In the absence of complete fracture lines, prophylactic fixation of the right femur was discussed but declined in favour of conservative management.
Conclusion:
This case describes the rare finding of two incomplete AFFs in one femur in association with a contralateral complete AFF. This is a reminder of the need for judicious use of bisphosphonates beyond 5 years. Stopping bisphosphonates may lower the risk of AFF by about 70% while teriparatide may reduce the time to healing of sugically treated AFFs. However, it's role in incomplete AFFs is less clear. Prophylactic surgery for incomplete AFF's is considered when there is pain or a fracture line. Furthermore, the natural history of incomplete AFFs is not determined with some healing spontaneously. Given that our patient has two incomplete AFFs, she may be at greater risk for fracture propagation and requires close clinical and radiographic monitoring.

Below: Complete AFF (left femur) and two incomplete AFFs (right femur)

P238

BODY COMPOSITION IN BARIATRIC SURGERY CANDIDATES

A. P. Barbosa[1], B. Gonçalves[2], M. Lopes[1], M. Severino[1], J. V. Rocha[1], J. Vieira[3], J. Camolas[3], E. Nobre[1], R. Lalanda[4], F. Nogueira[4], O. Gomes[4], A. Paulino[5]

[1]Endocrinology Department. ULS Santa Maria. Faculty of Medicine Lisbon University., Lisboa, Portugal; [2]Faculty of Medicine Lisbon University, Lisboa, Portugal; [3]Endocrinology Department. ULS Santa Maria, Lisboa, Portugal; [4]Surgery Department. ULS Santa Maria., Lisboa, Portugal; [5]Imagiology Department. ULS Santa Maria, Lisboa, Portugal

Introduction: Obesity is a multifactorial chronic conditon impacting the body composition (lean, fat and bone masses) and the cardiometabolic health. Bariatric surgery can have negative effects on bone health and increases the risk of fragility fratures. Its complex physiopathology includes hormonal, mechanical and nutritional factors.

Aims:

This study aimed to determine the body composition in candidates to obesity surgery.

Methods: The study included individuals with BMI ≥ 35 kg/m² candidates to obesity surgery, followed in both Endocrinology and Surgery Departments. Anthropometric data were evaluated and a DXA scan (*Hologic Horizon A*^{R}) was done to assess the body composition including BMD and lean and fat masses. The statiscal analysis was done with software SPSS®, version 29.

Results: 20 individuals, 16(80%) females, mean age 51.3±9.1 years and mean BMI 41.7±1.4 Kg/m^2. The total fat and lean masses (Kg) were 49.9±10.4 and 63.8±11.3, respectively. The fat and lean masses índices (Kg/m^2) were 17.9±4.2 and 22.8±2.9 respectively, while the apendicular lean mass index was 9.6±1.2. The android-to-gynoid (A/G) ratio was 1.13±0.1 and the mean area of visceral adipose tissue was 237.7±85.3 cm^2 (males 332 cm², females 214 cm²). Mean total BMD L1-L4 (g/cm^2) was 1.004±0.2 (mean Z-score -0.30±1.7 SD) for females and 1.050±0.1 (mean Z-score 0.0±0.8 SD) for males. Mean total BMD femoral neck (g/cm^2) was 0.84±0.1 (mean Z-score 0.1±1.3 SD) for females and 0.94±0.1 (mean Z-score 0.8±0.8 SD) for males. Regarding BMD classification, there were no cases of osteopenia/osteoporosis in men, while 4 women had osteopenia and 1 had osteoporosis.

Discussion and Conclusions:

The A/G ratio and the area of visceral adipose tissue of this population showed values higher than cardiometabolic risk thresholds. That was mainly true for the male population which showed a higher both A/G ratio and visceral adipose tissue area. There were no cases of sarcopenia and appendicular lean mass was above the respective diagnostic limits. However, in the female group there were 25% cases of osteopenia/osteoporosis. This study highlights the importance of studying the body composition in candidates to bariatric surgery, in order to early diagnose bone fragility, sarcopenia and cardiometabolic risk factors, thus allowing for preventive therapeutic measures.

P239

OPPORTUNISTIC DIAGNOSIS OF OSTEOPOROTIC VERTEBRAL FRACTURES THROUGH CT-SCAN

J. V. Rocha[1], A. Azeiteiro[2], M. L. Urbano[2], M. Fonseca[3], A. Gomes[3], J. Leitão[2], A. P. Barbosa[1]

[1]Endocrinology Department. ULS Santa Maria. Faculty of Medicine Lisbon University., Lisboa, Portugal; [2]Imagiology Department, ULS Santa Maria Lisboa, Lisboa, Portugal; [3]Endocrinology Department, ULS Santa Maria Lisboa, Lisboa, Portugal

Osteoporosis is a bone metabolic disease characterized by compromised bone strenght predisposing to fragility fractures.

Although vertebral fractures (VF) are among the most common ones, they remain substantially underdiagnosed and undertreated. Opportunistic diagnosis of vertebral fractures through CT-scan has been proposed as an efficient method for VF detection allowing for osteoporosis identification and early patient treatment.

Objectives: To identify patients with vertebral fractures through thoracic, abdominal and pelvic CT scans performed for other diagnostic purposes, diagnose and treat osteoporosis.

Material and Methods: prospective study conducted from October 2023 to September 2024.

CT scans were analysed and those with at least one VF were selected to enter the study.

Exclusion criteria: active oncological disease, chronic kidney disease, severe psychiatric disease or substance abuse; those already receiving osteoporosis treatment, those followed in endocrinology/rheumatology clinics and those lacking essential clinical information were included only for demographic analysis. The eligible patients underwent clinical evaluation and biochemical and DXA testing. Antiresorptive therapy was initiated when appropriate. Statistical analyses were performed using Excel®.

Results: From a total of 430 CT scans, 206 patients were identified with VF, 64 were excluded and 68 died during the data-collection period. Seventy-four patients (40 [54%] females) were eligible for osteoporosis

assessment, and 16 ultimately attended the clinical evaluation. Deceased patients were significantly older (84 vs. 75 years, p < 0.01) and more frequently had ≥2 vertebral fractures (47% vs. 28%, p = 0.02). Twelve patients (16%) had a previously known fragility fracture, 28% were active smokers, 22% were on oral anticoagulants, 32% were on antidepressants/antipsychotics and 20% were on corticosteroids. Mean PTH level was 88.1 ± 87.5 pg/mL (14-72 pg/mL), and mean serum 25-hydroxyvitamin D was 20.5 ± 15.1 ng/mL.

Conclusions: Within one year, opportunistic CT-scan evaluation identified 74 patients eligible for osteoporosis management. Notably, 68 patients died before their eligibility could be determined, underscoring both the vulnerability of this population and the need for earlier detection. Our findings reinforce that osteoporosis remains underrecognized and undertreated. Opportunistic VF detection on routine CT scans represents a valuable and efficient strategy to identify high-risk individuals who might otherwise remain undiagnosed.

P240

SLEEP QUALITY IN COMMUNITY RHEUMATOLOGY PATIENTS: RESULTS OF A MULTICENTER OBSERVATIONAL STUDY

X. G. Grapton[1], P. L. Lemesle[2], L. P. Poulain[3], A. L. Leboime[4], A. P. Pflimlin[4]

[1]Hôpital Suisse de Paris, ISSY LES MOULINEAUX, France; [2]Hopital Rives de Seine, Courbevoie, France; [3]Private Practice, Bezons, France; [4]Hopital Ambroise Paré, Boulogne Billancourt, France

Objectives

To evaluate sleep quality (SQ) in community-based rheumatology patients according to rheumatic conditions, comorbidities, treatments, and lifestyle habits, and to compare results with those of the general population (GP).

Methods

A cross-sectional observational study was conducted by fifteen rheumatologists in the Paris region and included 180 consecutive patients. Sleep duration, sleep quality, sleep disturbances, contributing factors, lifestyle habits, and the impact of physical activity were analyzed.

Results

The cohort consisted of 75% women (80% postmenopausal), with a mean age of 66.4 years and a mean BMI of 26.4 kg/m². Mechanical rheumatic disorders were predominant (72.5%), while inflammatory diseases accounted for 60.5%. The most frequent conditions were osteoarthritis (37.7%), low back pain (24%), rheumatoid arthritis (15.4%), osteoporosis (9.7%), spondyloarthritis (8.6%), tendinitis (8.6%), polymyalgia rheumatica (6%), and psoriatic arthritis (5%).

Mean sleep duration was shorter than in the GP (6 h 44 min vs 6 h 58 min), with longer sleep onset latency (34 vs 25 minutes). Only 26% of patients reported good SQ compared with 35% in the GP. Sleep quality was rated as average in 46%, poor in 9%, and very poor in 19%. SQ was better in inflammatory than in mechanical disorders, except for spondyloarthritis, which was associated with severe pain-related sleep disruption.

Sleep disturbances were reported by 92.5% of patients, particularly women. Nocturia, anxiety, and pain were the main contributing factors. Physical activity improved SQ in 51.6% of patients, especially morning exercise, gym-based activity, and sessions lasting less than 3.5 hours per week. Tea, coffee, and corticosteroids were not associated with impaired sleep.

Conclusion

Sleep disturbances are highly prevalent in community rheumatology patients, particularly in mechanical disorders. Despite frequent use of hypnotics and anxiolytics, sleep complaints remain insufficiently addressed. Systematic screening and targeted management should be integrated into routine rheumatologic care.

P241

MACHINE LEARNING FOR OSTEOPOROSIS RISK PREDICTION IN THAILAND'S AGING POPULATION

A. P. Phruetthiphat[1], P. Pinijprapa[1], D. R. Homsapaya[2]

[1]Phramongkutkalo Hospital, Bangkok, Thailand; [2]Kasetsart University, Sriracha, Thailand, Chon Buri, Thailand

Introduction

Osteoporosis poses a significant public health challenge for older adults in Thailand. As of 2022, the elderly population (≥60 years) exceeded 12 million, representing over 18% of the total populace [1]. An estimated 25% of this group (approximately 3 to 4 million individuals) are affected by or at high risk of osteoporosis. The projected rise in hip fracture incidence is concerning, estimated to reach 450–780 cases per 100,000 elderly by 2025 [2]. These fractures carry severe consequences: around 20% mortality within one year and up to 40% long-term disability [3]. Critically, 80–90% of at-risk individuals remain undiagnosed and untreated, indicating a major gap in current prevention strategies.

Purpose

This study's primary purpose, developed in collaboration with orthopedic and radiologist specialists, was to develop and validate a machine learning model capable of accurately predicting osteoporosis risk using routine clinical data from elderly patients. A secondary aim was to quantify the relative importance of key bone health indicators, specifically Trabecular Bone Score (TBS), alongside Bone Mineral Density (BMD) and Body Mass Index (BMI), to enhance early detection and improve decision-making for proactive fracture prevention in Thailand's aging society.

Methods

This analysis utilized clinical health data from 5,000 individuals to identify osteoporosis risk factors. Key variables included demographic information (age, sex), clinical data (BMI, and ICD9 codes), Trabecular Bone Score (TBS), and Bone Mineral Density (BMD). The modeling pipeline was implemented in Python using the scikit-learn framework. Feature selection was performed using Sequential Forward Floating Selection (SFFS), followed by supervised model training on the processed data, which included applying SMOTE (Synthetic Over-sampling Technique) to balance the dataset and improve detection of underrepresented cases. To ensure clinical relevance and interpretability, SHAP (SHapley Additive exPlanations) values were applied to quantify feature contribution. Exploratory analysis involved visualizing the distributions of Age, TBS, and BMD to identify patterns and potential risk thresholds, consistent with standard clinical assessment goals (e.g., determining the proportion of individuals with T-scores ≤−2.5 for osteoporosis).

Results

The analysis revealed established clinical patterns: a negative correlation was observed between age and BMD, and between age and TBS, confirming that bone density and microarchitecture tend to decline with aging. A significant positive correlation (r=0.79) was found between TBS and BMD, highlighting their complementary roles. The evaluation of multiple machine learning algorithms (logistic regression, SVM, random forests, XGBoost) identified XGBoost as the top performer, achieving an AUC of 0.98. Feature importance analysis using SHAP confirmed that

TBS ranked as a top predictor, alongside BMD and BMI, reinforcing its value as a key indicator of bone quality and fracture risk. The model also noted a relationship between dyslipidemia (elevated lipid levels) and increased osteoporosis likelihood.
Conclusion
The interdisciplinary integration of clinical expertise and data science successfully yielded a high-performing machine learning model (XGBoost, AUC = 0.98) for osteoporosis risk prediction. The findings underscore that relying solely on BMD is insufficient; incorporating TBS significantly enhances predictive accuracy and interpretability. The final model provides a valuable, proactive tool for identifying high-risk individuals early, thus supporting clinical decision-making and offering the potential to reduce the national burden of osteoporotic fractures in Thailand's rapidly growing elderly population.

P242

PREDICTORS FOR POOR OUTCOME AFTER HIP REPLACEMENT FOR ELDERLY FEMORAL NECK FRACTURE

A. P. Phruetthiphat[1], C. Patamamongkonchai[1], P. Siriamornthep[1], Y. Plumarom[1]

[1]Phramongkutkalo Hospital, Bangkok, Thailand

Introduction

Hip fractures among the elderly represent a significant public health issue, characterized by elevated mortality, morbidity, and healthcare expenditures. While bipolar hemiarthroplasty (BHA) is the standard treatment for displaced femoral neck fractures, long-term functional outcomes remain inconsistent. Research has predominantly focused on surgical techniques and mechanical failures, with limited exploration of non-surgical factors such as patient comorbidities and cognitive status.

Effective recovery hinges on precise surgical intervention and immediate postoperative mobilization to minimize complications. We hypothesize that optimal functional outcomes rely on a combination of surgical efficiency and baseline patient characteristics, including pre-injury ambulatory status and cognitive health. Identifying independent predictors is critical for risk stratification and the formulation of targeted care protocols.

This study aims to identify predictive factors associated with poor functional outcomes in elderly patients undergoing BHA for isolated femoral neck fractures. Additionally, we seek to develop and validate the Integrated Scoring System in Elderly Patients with Isolated Femoral Neck Fractures (ISSIFN) as a clinical tool for predicting functional recovery.
Materials and Methods

Settings and Subjects: This retrospective study was conducted between January 2015 and December 2021. It included elderly patients with low-energy femoral neck fractures who underwent BHA, with a minimum follow-up of two years. Exclusion criteria encompassed pathological fractures, high-energy trauma, bilateral fractures, and insufficient medical records, resulting in a final cohort of 399 patients.

Measurements: Demographic and clinical data were collected from electronic medical records, including age, gender, comorbidities, and surgical parameters. The Charlson Comorbidity Index (CCI) and the American Society of Anesthesiologists (ASA) classification assessed preoperative physical condition. Cognitive impairment was evaluated using the Mini-Mental State Examination (MMSE), with scores under 25 indicating cognitive impairment.
Surgical Procedure and Postoperative Management: All patients underwent BHA via the piriformis-sparing approach, preserving key muscles while ensuring joint stability. Postoperative pain management protocols were standardized, allowing for weight-bearing as tolerated when patients reported mild pain.

Outcome Measurements: Patients were followed at multiple intervals, with functional outcomes assessed using the Harris Hip Score (HHS). Scores were classified into good (80–89) and non-good (<80) outcomes, with deaths within two years categorized as non-good outcomes.

Statistical Analysis: Data analysis was performed using STATA version 14.0. Descriptive statistics summarized demographic data, while multivariate logistic regression identified predictors of functional outcomes.

Development and Validation of the Integrated Scoring System

The ISSIFN was developed from the cohort, utilizing logistic regression to determine associations between predictors and outcomes. The score was calculated based on regression coefficients, and receiver operating characteristic (ROC) curve analysis established a cut-off score for optimal predictive power.
Results

Participant Flow and Baseline Characteristics

From an initial cohort of 605 patients treated with bipolar hemiarthroplasty (BHA), 399 were included in the final analysis after excluding individuals with pathological fractures, prior revisions, or insufficient follow-up data. The population was predominantly female (77.44%), with a mean age of 80.14 ± 7.9 years. Physical status assessment indicated that 50.75% were classified as ASA 3, reflecting severe systemic disease, and the mean Charlson Comorbidity Index (CCI) was 4.29 ± 1.21. Cognitive impairment, defined as a Mini-Mental State Examination (MMSE) score <25, was present in 12.03% of participants.

Surgical and Clinical Parameters

All patients underwent BHA via a piriformis-sparing approach. The mean hip bone mineral density (BMD) T-score was -2.37 ± 1.22, while the average serum vitamin D level was 26.18 ± 12.89 ng/ml. Notably, 85.21% of patients experienced a time-to-operation exceeding three days, and 13.53% had a time-to-rehabilitation greater than three days. At the two-year follow-up, functional outcomes were assessed using the Harris Hip Score (HHS), revealing "poor" outcomes (HHS <80 or mortality) in 47 patients.

Development of the ISSIFN Scoring System

Univariable analysis demonstrated that age ≥80, ASA 3, cognitive impairment, and pre-fracture dependency were significantly associated with poor outcomes ($p < 0.05$). Multivariable logistic regression identified five independent predictors for the ISSIFN: Cognitive Impairment (6 points; aOR: 421.25), Time to Operation > 3 days (4 points; aOR: 45.60), Time to Rehabilitation > 3 days (3 points; aOR: 15.99), Pre-fracture Dependency (2 points; aOR: 7.24), BMD < -2.5 (2 points; aOR: 5.76).

Validation and Model Performance

The ISSIFN demonstrated excellent discriminatory power with an Area Under the ROC Curve (AUC) of 0.9331. The optimal cut-off score, determined by the Youden Index, was 8.5. At this threshold, the ISSIFN predicted poor functional outcomes with a sensitivity of 89% and specificity of 85%.

Discussion

The ISSIFN score offers a robust, objective framework for predicting long-term functional outcomes in elderly hip fracture patients. The data indicate that while biological factors, such as bone mineral density, are important, cognitive status and timelines for care are the most significant predictors of success.

The substantial adjusted odds ratio for cognitive impairment (aOR: 421.25) indicates that patients with MMSE scores <25 are at extreme risk for poor outcomes, likely due to their inability to adhere to essential postoperative protocols. Additionally, the 45-fold increase in the odds of poor outcomes associated with surgical delays beyond three days (aOR: 45.60) highlights a critical bottleneck in care.

Despite the benefits of the piriformis-sparing approach, these advantages are diminished if rehabilitation is delayed beyond three days. By utilizing the ISSIFN cut-off of 8.5, clinicians can quickly identify high-risk patients upon admission, enabling the implementation of intensified orthogeriatric care and expedited rehabilitation pathways to reduce the likelihood of poor functional outcomes.

Conclusion

The ISSIFN is a highly sensitive and specific tool for predicting functional outcomes following bipolar hemiarthroplasty. Prioritizing cognitive assessment and minimizing surgical and rehabilitative delays are crucial strategies for enhancing the quality of life in this vulnerable population.

P243

EVALUATION OF OSTEOSARCOPENIA OF THE ELDERLY FROM THE REPUBLIC OF MOLDOVA

A. Popescu[1], G. Soric[1], A. Popa[2], A. Botezatu[1], N. Bodrug[1], A. Negara[3]

[1]Aging and Age Study Laboratory, Discipline of Geriatrics and Occupational Medicine, Department of Internal Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova; [2]Aging and Age Study Laboratory, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova; [3]Discipline of Geriatrics and Occupational Medicine, Department of Internal Medicine, "Nicolae Testemitanu" State University of Medicine and Pharmacy, Chisinau, Moldova

Background. The aging process involves a series of age-related musculoskeletal physiological changes, which represent an important indicator of health status, with a significant impact on the autonomy.
The purpose of the study was to evaluate the prevalence of osteosarcopenia and its association with age related changes in the elderly.
Material and Methods. The descriptive epidemiologic study included 613 elderly (73.16±0.24 years), who were examined according to clinical evaluation, laboratory and complex geriatric assessment(CGA). Based on the Canadian Classification of the elderly, 3 comparable groups were formed: young elderly(65-74 years) – 417(49.59%), mature elderly - 162(26.43%) and old elderly – 34(5.54%). Osteosarcopenia was diagnosed according to EWGSOP2 2018 criteria for sarcopenia and WHO criteria for osteoporosis.
Results. The weight of osteosarcopenia constituted 35.73% of patients from the general group, the highest was determined in the old elderly – 64.71% vs mature elderly – 48.15% vs young elderly – 28.54%($p<0.05$). A greater number of old, compared to mature and young elderly, met the criteria for osteosarcopenia: SARC-F – 6.79±0.44 pt. vs 5.34±0.21 pt. vs 3.77±0.12 pt., p=0.001; dynamometry – 16.82±1.4 kg vs 19.68±0.1 kg vs 24.76±0.56 kg, p=0.003; MMT – 40.35±3.44 kg vs 44.73±1.21 kg vs 55.42±1.09 kg, p=0.001; physical performance SPPB – 3.94±0.60 pt. vs 6.79±0.26 pt. vs 8.21±0.15 pt., p=0.0001; T-score -2.72±0.19 DS vs -2.63±0.08 DS vs -2.11±0.25 DS, p=0.002. The prevalence of osteoporosis by study groups was higher for the old elderly group 67.65%, then mature 5.88% and young 46.52%. The osteosarcopenia syndrome correlated with the severity of the frailty syndrome (r=0.50; p=0.05), with decreased autonomy (ADL, r=-0.59; p=0.05; IADL, r=-0, 63; p=0.05), presence of depression - DGS, r=0.42; p=0.05 and with MMSE cognitive disorders, r=-0.42; p=0.05. The value of 25-OH-Vitamin D per study group was: old elderly – min. value. 4.6 ng/ml, max. value 35.47 ng/ml; mature elderly - min. value 4.98 ng/ml, max. value 60.59 ng/ml; young elderly - value min. 20.17 ng/ml, max. value 86 ng/ml.
Conclusion. The osteosarcopenia syndrome was more frequently determined for old elderly patients with a major impact on both autonomy - cognitive and emotional status.
Key-words: osteosarcopenia, osteoporosis, elderly.

P244

MULTIFOCAL ATHEROSCLEROTIC VASCULAR DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Potapova[1], I. Kirillova[1], A. Semashko[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Introduction. Rheumatoid arthritis is a disease with high cardiovascular risk.
Objective. To assess the frequency of multifocal atherosclerosis (MFA) and its relationship with clinical manifestations in patients with rheumatoid arthritis (RA).
Materials and methods. The study included 100 patients with a confirmed diagnosis of RA. The mean age of the patients was 48.5±10.3 years; the majority were women (83%). The median disease duration was 120.0 [62.0; 204.0] months. Seropositivity for RF was detected in 73% of patients, and for ACCP in 78%. According to the DAS28-CRP index, 20% of patients had moderate disease activity, and 80% had high activity. The advanced stage of RA was diagnosed in 75% of patients, and the late stage in 23%. The mean values of activity indices were: SDAI - 33.3±10.8, CDAI - 31.3±10.2. The median ESR was 38.0 [24.0; 58.0] mm/h, and CRP - 12.3 [6.1; 27.4] mg/l. Joint erosions at the time of inclusion in the study were present in 79% of patients. According to radiographic examination, most patients had stage 2 (54%) or stage 3 (26%) disease. Systemic manifestations of RA were noted in 41% of the examined patients. Traditional CVD risk factors were identified in 62.0% of RA patients: overweight (BMI > 25 kg/m²) - in 44.0%, family history of cardiovascular pathology - in 31.0%, sedentary lifestyle - in 43.0%, arterial hypertension - in 41.0%. At the time of the study, 8.0% of patients were smokers. Atherosclerotic lesions of the common carotid (CCA) and femoral (FA) arteries were assessed using ultrasound Dopplerography, determined

by the presence of an atherosclerotic plaque (AP). The coronary artery calcium (CAC) was evaluated using a 32-row computed tomography scanner according to the standard Agatston method.
Results. Among the examined patients, APs were detected in 26 (45.6%) individuals. In terms of localization, APs were found in the CCA in 33.0% and in the FA in 34.0%. An elevated CAC according to MSCT was established in 17.0% of patients. Ultimately, the diagnosis of multifocal atherosclerosis (MFA) was verified in 25 (25.0%) of the studied individuals. We divided the patients into two groups: with MFA and without MFA. When comparing the groups, it was found that patients with MFA were significantly older ($p<0.001$) and had a higher BMI ($p<0.05$), however, no statistically significant differences were found in RA duration ($p=0.66$). Furthermore, in the MFA group, there were significantly more patients with swollen ($p<0.05$) and painful joints ($p<0.01$). In patients with MFA, the CCA IMT was greater: 0.60 mm [0.57; 0.69] versus 0.57 mm [0.50; 0.64] in patients without MFA ($p<0.05$). The FA IMT was also significantly greater in patients with MFA. For the FA, the IMT was 0.63 mm [0.55; 0.80] versus 0.56 mm [0.47; 0.68] in the group without MFA ($p<0.05$). The FA IMT demonstrated a direct correlation with disease activity indices: DAS28-CRP, SDAI, and CDAI ($r=0.4$).
Conclusion. It was established that multifocal atherosclerosis is detected in 25% of patients with RA. Its presence correlates with higher arthritis activity. This justifies the need for active screening for atherosclerosis, especially in the femoral arteries, in RA patients with high disease activity, regardless of the disease duration.

P245

THE EFFECT OF ALBANIAN URBAN LYRIC MUSIC ON PATIENTS WITH SARCOPENIA

A. Pulaj[1], E. Mihali[1], E. Rapushi[2], V. Salko[2], A. Zoto[2]

[1]European University of Tirana (EUT), Tirana, Albania; [2]UHC Mother Theresa, Department of Internal Medicine, Tirana, Albania

Objective: Evaluating the effect of urban lyric music on patients with sarcopenia
The muscle function and mass loss with age is a natural phenomenon. In the seventh and eighth decades of life, muscle strength decreases by 20-40% and the rate of reduction gradually increases with age. In patients with sarcopenia, the serum cortisol level is dysregulated, which further increases the stress level in them.
Material and methods: In total, 163 patients diagnosed with sarcopenia were included in the study: 92 women (56.4%) and 71 men (43.5%). Sarcopenia was defined as a relative skeletal mass index (SMI) of ≤ 5.77kg/m2. The mean age of the study group was 67±3.4 years. All patients were assessed for serum cortisol levels at 8 a.m. (5-23 mcg/dL) and 4 p.m. (3-13 mcg/dL) and SMI at baseline and on the 90th day of the study. All patients were referred to listen to 45-60 minutes per day of urban lyric music in the early morning and afternoon hours, by Albanian singers such as Tefta Tashko Koço, Marije Kraja, Jorgjie Truja and works by composer Lola Gjoka, for 90 days. Individuals suffering from diseases that affect muscle mass or receiving treatment that influence serum cortisol levels, were excluded from this study.
Results: At the beginning of the study, the SMI level of the patients was 3.5.93±0.66kg/m2. The serum cortisol level at the beginning of the study showed oscillations, with increased values at 8 a.m., 43±6.7 mcg/dl and at 4 p.m., 23±4.3mcg/dl. On the 90th day of the study, a period in which patients were treated with listening to Albanian urban lyric music twice a day for 45-60 minutes, the SMI value was 4.1±0.9kg/m2 and the serum cortisol level was at 8 a.m., 25±1.6mcg/dl and at 4 p.m., 16±0.9mcg/dl. A correlation was found between serum cortisol levels and muscle mass in the study group ($p<00.5$, $r=1$). The data confirms an improvement in serum cortisol levels in patients after 90 days of treatment with listening to Albanian urban lyric music.
Conclusion: The study shows that Albanian urban lyric music affects blood cortisol levels and directly influences the muscle mass levels. This music affects the reduction of stress levels and the improvement of serum cortisol levels, reducing the rate of muscle catabolism.

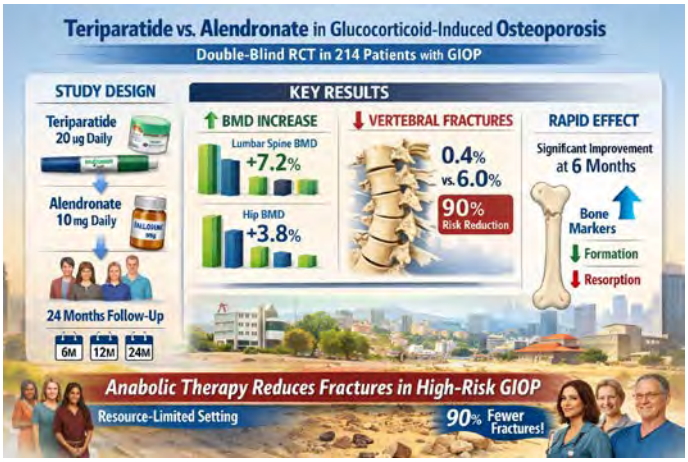
HOW GOOD I FEEL WITH A CORTISONE PILL !

M. Campaniolo[1], A. Pulcina[2], L. Gifuni[1], B. Presciuttini[2]

[1]Università Vita-Salute San Raffaele, Milano, Italy; [2]ASST Mantova, Mantova, Italy

Glucocorticoids-induced osteoporosis (GIOP) affects 0.7-1.5% of adults in the world. An estimated 30% of long-term glucocorticoids (GC) users develop secondary osteoporosis. GIOP patients most often experience spine fractures, whom risk is 2.5-3 fold higher than general population. Hip fracture is the second most common fracture. Since the first 3 months of GC treatment are critical for bone loss, adequate prevention of GIOP should be immediately implemented through lifestyle modification and calcium and vitamin D supplementation. In addition, anti-resorptive therapy should also be promptly considered.
A 74-years-old woman came to our attention for an initial evaluation due to 3 vertebral fractures, all of which occurred in recent years without traumatic events. She had never been treated with anti-osteoporosis drugs. We studied the main risk factors for osteoporosis, such as early menopause, family history, smoking, alcohol consumption, and diseases or therapies known to cause secondary forms of osteoporosis. Her entire medical history was negative for the identification of a clear predisposing factor. Bone densitometry showed osteoporosis (T-score in lumbar tract -2.7 SD, at femoral neck -2.5 SD), unchanged since menopause. So our patient had 3 major fragility fractures without any predisposing factors. How strange! Finally, we asked her again if she had ever been subjected to chronic treatment with GC and got the answer: she confessed that for several years she had been taking oral prednisone 50 mg (2-3 times a week) for analgesic purposes without medical advice. She had clearly undervalued the harmful effects in light of the significant perceived benefits on pain.
In conclusion, we recommend always taking a complete medical history and carefully assessing the main fracture risk factors, paying particular attention to the use of as-needed glucocorticoids, whose side effects on bone are underestimated by most patients and whose use is often not reported to physicians.



P247

TERIPARATIDE VERSUS ALENDRONATE IN GLUCOCORTICOID-INDUCED OSTEOPOROSIS: A DOUBLE-BLIND RANDOMIZED CONTROLLED TRIAL WITH FRACTURE OUTCOMES FROM A RESOURCE-LIMITED SETTING

A. Qadir[1], M. Muzzammil[1]

[1] Sindh government services hospital karachi, Karachi, Pakistan

Background:
Glucocorticoid-induced osteoporosis (GIOP) is a major cause of secondary osteoporosis and fragility fractures, particularly in low- and middle-income countries where long-term steroid use is common. Evidence directly comparing anabolic and antiresorptive therapies in patients at high fracture risk remains limited. This study compared the efficacy, fracture outcomes, and mechanistic effects of teriparatide versus alendronate in established GIOP.
Methods:
In this double-blind randomized controlled trial, 214 adults (22–65 years) receiving long-term glucocorticoid therapy (≥5 mg/day prednisone equivalent for ≥3 months) with osteoporosis were randomized to daily subcutaneous teriparatide (20 µg, n=107) or oral alendronate (10 mg, n=107), with calcium and vitamin D supplementation. Primary outcome was percentage change in lumbar spine bone mineral density (BMD). Secondary outcomes included total hip BMD, vertebral fracture incidence, early treatment response, bone turnover markers, and safety over 24 months.
Results:
Significant between-group differences in lumbar spine BMD were evident as early as 6 months ($P < 0.001$). At 24 months, lumbar spine BMD increased by 7.2 ± 0.7% with teriparatide versus 3.4 ± 0.7% with alendronate ($P < 0.001$). Total hip BMD gains were also greater in the teriparatide group (3.8 ± 0.6% vs. 2.4 ± 0.6%; $P = 0.005$). New vertebral fractures occurred significantly less frequently with teriparatide compared with alendronate (0.4% vs. 6.0%; $P = 0.004$), representing an approximate 90% relative risk reduction. Teriparatide produced marked increases in bone formation markers, consistent with its anabolic mechanism, while alendronate primarily suppressed bone resorption. The greatest skeletal benefits were observed in patients with prior vertebral fractures and very low baseline BMD. Both treatments were generally well tolerated, with no significant differences in serious adverse events.
Conclusion:
In patients with glucocorticoid-induced osteoporosis at high fracture risk, teriparatide provided earlier and significantly greater improvements in spinal and hip BMD and substantially reduced vertebral fracture incidence compared with alendronate. These findings support an anabolic-first treatment strategy for severe GIOP, particularly in high-risk patients, and are highly relevant for resource-constrained healthcare systems where fracture-related disability carries major socioeconomic consequences.
Keywords: Glucocorticoid-induced osteoporosis, Teriparatide, Alendronate, Vertebral fractures, Bone mineral density

P248

OSTEOSARCOPENIA: A HIGH-RISK PHENOTYPE FOR FRACTURES, HOSPITALIZATIONS, AND MORTALITY IN OLDER ADULTS

A. Qadir[1], M. Muzzammil[1]

[1]sindh government services hospital karachi, Karachi, Pakistan

Background:
Osteosarcopenia, the coexistence of osteoporosis and sarcopenia, is increasingly recognized as a high-risk phenotype in older adults. While both conditions individually increase fracture and mortality risk, their combined impact remains underexplored. Early identification may guide interventions to reduce adverse outcomes.

Methods:
We conducted a prospective cohort study of **1,200 community-dwelling adults aged ≥65 years** (mean age 72.4 ± 5.6; 58% female). Osteoporosis was defined by **DXA T-score ≤ −2.5** and sarcopenia by **EWGSOP2 criteria** (low muscle mass + low strength). Participants were categorized as: neither, osteoporosis only, sarcopenia only, or osteosarcopenia. Outcomes included **incident fractures, hospitalizations, functional decline, and all-cause mortality** over 3 years. **Cox proportional hazards models** adjusted for age, sex, BMI, comorbidities, and medications.

Results:
Osteosarcopenia prevalence was **12%**, osteoporosis only 28%, sarcopenia only 14%, and neither 46%. Fracture incidence was **28% in osteosarcopenia** vs 15% (osteoporosis only), 12% (sarcopenia only), and 5% (neither). Adjusted hazard ratios (osteosarcopenia vs neither) were: **fractures 5.2 (3.4–7.8), hospitalizations 2.8 (1.9–4.1), mortality 3.6 (2.2–5.9); $p < 0.001$** for all. Functional decline was faster in osteosarcopenia (gait speed −0.15 m/s/year, SF-36 physical score 12 points, $p < 0.01$). Kaplan–Meier analysis showed the steepest decrease in fracture-free and overall survival for osteosarcopenia.

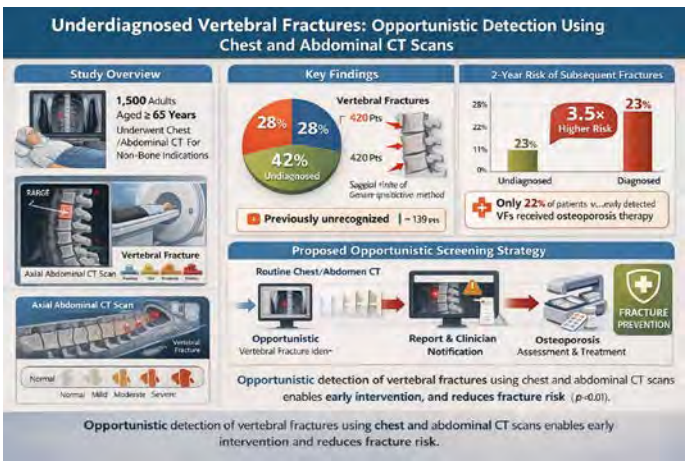
Conclusion:
Osteosarcopenia is a high-risk phenotype associated with fractures, hospitalizations, functional decline, and mortality. Integrated assessment and interventions targeting **both bone and muscle health** are essential. Recognition of osteosarcopenia as a distinct clinical entity may improve risk stratification and guide preventive strategies.

P249

UNDERDIAGNOSED VERTEBRAL FRACTURES: OPPORTUNISTIC DETECTION USING CHEST AND ABDOMINAL CT SCANS

A. Qadir[1], M. Muzzammil[1]

[1]sindh government services hospital karachi, Karachi, Pakistan



Background:
Vertebral fractures (VFs) are the most common osteoporotic fractures but are frequently **underdiagnosed**, delaying treatment and increasing risk of subsequent fractures. Routine chest or abdominal CT scans performed for other indications may allow **opportunistic detection** of VFs, improving early diagnosis and intervention.

Methods:
We retrospectively analyzed **1,500 adults aged ≥65 years** who underwent chest or abdominal CT. VFs were assessed using the **Genant semi-quantitative method**. Clinical records were reviewed to determine prior recognition and osteoporosis treatment. Outcomes included **prevalence of undiagnosed VFs, subsequent fracture risk, and treatment initiation**. Logistic regression adjusted for age, sex, BMI, and comorbidities.

Results:

- VFs were present in **28% (n=420)**; **67% (n=281)** were previously unrecognized.
- Undiagnosed VFs were associated with a **3.5-fold higher risk of subsequent fractures** (HR 3.5, 95% CI 2.1–5.8, p < 0.001).
- Only **22% of patients** with newly identified VFs received osteoporosis therapy.
- Older age, male sex, and higher BMI independently predicted underdiagnosis (p < 0.05).

Conclusion:
Vertebral fractures are frequently missed but can be opportunistically detected on routine CT scans. Early identification enables **timely intervention**, reducing fracture risk and morbidity. Integrating vertebral fracture assessment into routine CT reporting, potentially with **automated or radiologist-driven tools**, represents a feasible strategy to improve osteoporosis care.

P250

THE IMPACT OF CONCOMITANT OSTEOARTHRITIS ON THE SEVERITY OF RHEUMATOID ARTHRITIS AND THE TREATMENT RESPONSE

A. R. Babaeva[1], E. V. Kalinina[2], V. P. Goloskova[1], K. S. Solodenkova[3], Y. V. Zakharov[1]

[1]Volgograd State Medical University, Volgograd, Russia; [2]Volgograd state Medical University, Volgograd, Russia; [3]Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Moscow, Russia

Introduction. The combination of rheumatoid arthritis (RA) with osteoarthritis (OA) is a common practical problem. In patients with RA onset at a young and middle age, OA is considered a secondary process caused by joint biomechanics disorders due to RA. The severity of RA depends on the disease activity, which is evaluated by indices that include mainly subjective indicators. The commonest index, DAS28-CRP/ESR, contains only one objective laboratory indicator: CRP or ESR. Additionally the severity of joint syndrome in patients with RA may be caused by secondary OA.
The aim of the present study was to assess the OA influence on the intensity of the joint syndrome and the response to the standard RA therapy.
Materials and methods. The study included 260 patients with a verified diagnosis of RA, 221 women (85%), 39 men (15%) aged from 28 to 83 years (mean age 58.2 ± 3.7 years), with established and late stage of the disease, 2-4 radiological stage. The vast majority of patients were seropositive for RF (82.3%) and ACCP (92.3%). All patients received standard therapy with traditional immunosuppressants, and 64 patients (24.6%) received biological or target drugs. 165 (63.5%) patients received systemic glucocorticoids (GC) in a persistent regimen, and 214 (82.3%) patients regularly took non-steroidal anti-inflammatory drugs. The activity of RA was assessed by the DAS28-CRP or DAS28-ESR indices, and the response to treatment was assessed by the dynamics of this index. The diagnosis of concomitant OA was performed based on the clinical features of the joint involvement and imaging data (X-ray, CT, MRI, sonography).
Results. In the observed group, 232 (89.2%) patients corresponded to the level of moderate and high RA activity, while 86 people (33%) did not show signs of active synovitis of small joints and joints of the upper extremities, and in 93 (35.8%) ESR and CRP did not exceed normal values. An unsatisfactory or insufficient response to treatment according to the dynamics of the DAS28-CRP/ESR index was noted in 127 patients, which is 48.9%. X-ray signs of OA were observed in 119 (45.8%) patients, with the frequency of OA reaching 57.5% (73 patients) in the non-responders subgroup, while OA was diagnosed less frequently in the responders – in 33.1% of cases (44 patients). When comparing demographic and clinical indicators in subgroups with concomitant OA (OA+) and without concomitant OA (OA-), significant differences were found in terms of average age, frequency of metabolic and cardiovascular diseases, frequency of use, and dose of GC. In the OA+subgroup, there was a significant excess of joint pain intensity according to VAS (7.92±0.96 and 5.04±0.87, respectively, t=2.2 p<0.05), general health assessment (86.3±6.15 and 53.18±7.91, respectively, t=3.3, p<0.05), as well as a significant decrease in the mean number of swollen joints (1.18±0.36

vs 3.23±0.85, t=2.32 p<0.05) and mean ESR (19.34±3.18 vs 28.46±2.12, t=2.2 p<0.05, t=2.24, p<0.05).
Conclusions. OA, detected in 45.8% of RA patients, is associated with older age, the presence of comorbid pathology, long-term use of GC, and worse response to standard anti-rheumatic therapy. Patients with a combination of RA and OA, in the absence of objective signs of active synovitis, have higher joint pain intensity and worse overall health indicators, with lower number of swollen joints and ESR. These results demonstrate a significant contribution of secondary OA to the intensity of joint involvement as well as to the standard treatment failure.

P251

EFFECTS OF TWO-YEAR DENOSUMAB TREATMENT ON HIP BONE ARCHITECTURE IN POSTMENOPAUSAL OSTEOPOROSIS ASSESSED BY DXA-BASED 3D MODELING

A. R. Hong[1], J. Y. Park[1], J. H. Yoon[1], H. K. Kim[1], H. C. Kang[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonnam National University Medical School, Gwangju, South Korea

Objective: Denosumab is a fully humanized monoclonal antibody targeting the receptor activator of nuclear factor κB ligand and has demonstrated robust efficacy in significantly increasing bone mineral density (BMD) and reducing fracture risk. However, data on the effects of denosumab on volumetric BMD (vBMD) remain limited. Given the increasing use of denosumab as both a first-line and sequential therapy, this study aimed to investigate its real-world effects on three-dimensional dual-energy X-ray absorptiometry (3D-DXA)–derived parameters, with particular attention to the influence of prior antiresorptive therapy.
Methods: This retrospective study included 101 postmenopausal women with osteoporosis who were treated with denosumab for two years and underwent DXA assessments both before and after treatment. In addition to areal BMD (aBMD), hip structural parameters were evaluated using 3D-Shaper software, including cortical and trabecular vBMD, integral vBMD (trabecular plus cortical), cortical surface BMD (sBMD), and cortical thickness.
Results: Among the study population, 51.5% (52/101) had a prior history of antiresorptive therapy. Patients with prior antiresorptive treatment were older than treatment-naïve patients (68.1 ± 7.8 vs. 63.9 ± 8.8 years, $P = 0.013$), while body mass index (BMI) was comparable between groups (22.1 ± 2.8 vs. 21.9 ± 2.6 kg/m², $P = 0.808$). After two years of denosumab treatment, significant increases in aBMD were observed at the lumbar spine (5.5 ± 4.5%), femoral neck (2.7 ± 6.6%), and total hip (3.2 ± 5.6%) (all $P < 0.001$). Three-dimensional DXA analysis demonstrated significant increases in integral vBMD (3.4 ± 6.1%, $P < 0.001$), trabecular vBMD (3.2 ± 13.3%, $P = 0.016$), and cortical vBMD (3.8 ± 6.9%, $P < 0.001$). Cortical sBMD and cortical thickness also increased significantly (4.7 ± 7.9%, $P < 0.001$; and 1.3 ± 4.6%, P = 0.008, respectively). After adjustment for age and BMI, no significant differences were observed in changes in aBMD or 3D-DXA parameters according to prior antiresorptive treatment history.
Conclusions: Two years of denosumab treatment resulted in significant improvements in both aBMD and 3D-DXA–derived parameters, including volumetric BMD, regardless of prior antiresorptive therapy history.

P252

REAL-LIFE INDICATIONS AND EFFECTIVENESS OF DENOSUMAB IN A HIGH-COMPLEXITY PUBLIC TERTIARY CENTER: A RETROSPECTIVE STUDY

M. K. G. Dias[1], T. C. Matos[1], L. P. C. Seguro[1], D. S. Domiciano[2], G. B. Polho[3], A. S. Franco[2]

[1]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Brazil; [2]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil; [3]Hospital Sírio-Libanês, São Paulo, Brazil

Objectives: To evaluate the real-life indications and therapeutic outcomes of denosumab in a specialized rheumatology-based osteoporosis clinic of a high-complexity tertiary public center, focusing on a population with significant comorbidities.
Material and Methods: Patients receiving denosumab for osteoporosis (OP) were identified at a tertiary referral hospital through a retrospective review of electronic medical records from January 2013 to December 2024. We analyzed demographics, indications for treatment, densitometric evolution, and bone turnover markers. For comparative analysis, patients were categorized based on prior osteoporosis treatment: prior use of zoledronic acid versus no prior use. Continuous variables are expressed as median [IQR] and categorical variables as (frequency, percentage). Differences between groups were assessed using Wilcoxon and Chi-square or Fisher's exact tests. All analyses were performed using R software.
Results: The study included 211 patients (median age 72.0 [63 - 82] years; 84.8% female). Prior exposure to oral bisphosphonates was reported in (181, 85.8%) patients, while (135, 64%) had used intravenous bisphosphonates (mainly zoledronic acid, n=114). Significant comorbidities included immune-mediated rheumatic diseases (39.8%), advanced kidney disease (32.7%), type 2 diabetes (14.7%) and smoking (8.5%). The most frequent indications were renal dysfunction (43.6%) and failure of intravenous bisphosphonate therapy (34.6%). Denosumab treatment resulted in a significant reduction in C-terminal telopeptide levels (delta −56%, p<0.001) and increased bone mineral density at the femoral neck (+5%, p=0.018), total hip (+3%, p=0.058) and lumbar spine (+3%, p=0.012). When comparing patients with prior zoledronic acid use to those without, a statistically significant difference was observed at the total hip (+1.7% [−4.5 - 8.8] vs. +8.9% [0.0 - 18.4]; p=0.037). At the lumbar spine and femoral neck, no significant differences were found between the groups (+2.6% [−2.2 - 8.1] vs. +7.0% [0.7 - 17.0]; p=0.124 and +7.2% [−3.9 - 16.4] vs. +4.7% [−0.5 - 24.4]; p=0.407, respectively). Regarding bone turnover, both groups showed comparable reductions in CTX levels (−57.7% [−72.7 - −17.9] vs. −51.1% [−64.2 - −11.9]; p=0.680).
Conclusions: In this real-world high-complexity setting, denosumab was predominantly indicated for patients with renal dysfunction and those failing intravenous bisphosphonates. The treatment effectively suppressed bone turnover and improved bone mineral density, demonstrating a blunted yet positive response in patients with prior zoledronic acid exposure. These findings support denosumab as a valuable therapeutic option for managing severe osteoporosis in multimorbid populations.

P253

MAPPING FRAGILITY FRACTURES IN STATE OF SÃO PAULO: DEMOGRAPHICS, OUTCOMES, AND REGIONAL VARIATION FROM REGULATION RECORDS

A. S. Franco[1], H. F. Kroes[2], C. F. Gomes[1], O. L. R. Fiorotto[1], K. Choma[1], V. L. N. Bonoldi[1], D. S. Domiciano[1], B. A. Miyamoto[1], G. B. Polho[3], F. K. Ogata[4], A. L. F. Lawand[4]

[1]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Brazil; [2]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil; [3]Hospital Sírio-Libanês, São Paulo, Brazil; [4]Central de Regulação de Ofertas de Serviços de Saúde, Secretaria Estadual de Saúde de São Paulo., São Paulo, Brazil

Objectives: Fragility fractures (FF) are increasingly straining health systems as populations age, yet Brazil still lacks recent, standardized population-based information to guide prevention strategies and service allocation. This study sought to map the epidemiologic profile of fragility fractures in São Paulo State by integrating patient-level demographic/clinical characteristics with location-based measures of occurrence/referral and broader socioeconomic/environmental contextual indicators.
Material and Methods: Retrospective study using the São Paulo State Hospital Regulation System (SIRESP) urgency/emergency orthopedic records from 2019 to 2023. Records from individuals <30 years, with incompatible diagnoses/high-energy trauma, or inconsistent data were excluded. Records were then subjected to manual review. The Spearman test was for temporal trend, ANOVA for latitude-band differences, and multivariable logistic regression for mortality predictors.
Results: Among 89,669 fragility fractures, patients were 73 ± 15 years on average and 67% were women. The main sites were proximal femur (52%), distal radius (22%), proximal humerus (16%), vertebral (2%), and multiple fractures (0.6%). In-regulation mortality was 0.2% (207 deaths), mostly after proximal femur fractures (95%). In femur fractures, mortality increased with age (OR 1.06/year, CI 1.05-1.08), male sex (OR 1.92, CI 1.44-2.55), and longer resolution time (OR 1.07/day, CI 1.05-1.08). From 2019 to 2023, annual volume rose 50.5% (12,967→19,517), with the steepest increases in distal radius (+83.2%) and vertebral (+72.0%) fractures. Fracture rates differed by latitude (212.7/100,000 at −25 to −23.7° vs 220.1/100,000 at −21.2 to −19.9°; p≤0.001), showing higher fracture rates but lower mortality at lower latitudes (p=0.01); Human Development Index (HDI) also varied by latitude but showed no clear association with fracture or mortality rates.
Conclusion: Fragility fractures increased substantially in São Paulo State and predominantly affected older women. Mortality predictors suggest that faster access to definitive care may improve outcomes. Latitude-related differences indicate regional heterogeneity, supporting localized prevention strategies and care-pathway optimization.

P254

CLINICAL FEATURES AND ASSESSMENT OF EPICARDIAL ADIPOSE TISSUE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND CHRONIC HEART FAILURE

A. Semashko[1], A. Potapova[1], I. Kirillova[1], T. Popkova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to evaluate the clinical features and thickness of epicardial adipose tissue (EAT) in patients with rheumatoid arthritis (RA) and chronic heart failure (CHF).
Materials and methods: the study included 100 patients with a reliable diagnosis of RA with high disease activity and insufficient therapy effectiveness. All patients underwent echocardiography with an assessment of the thickness of the EAT along the anterior wall of the right ventricle. CHF was assessed according to the recommendations of the European Society of Cardiology.
Results: All RA patients were divided into groups – without CHF (n=39), with the pre-stage of CHF (n=35) and with the presence of CHF (n=26). The thickness of the EAT was 5.8 [2.4; 10.1] mm. In the group without CHF – 5.5 [2.4; 8.4] mm, in the group with pre-stage of CHF – 5.6 [2.4; 9.0] mm, in the group with CHF – 6.4 [2.5; 10.1] mm. When evaluated by groups, significant differences in the thickness of the EAT were noted (p=0.08). There was a direct correlation of EAT with the age of patients in the entire group (r=0.3, p <0.05), as well as in the group of patients with CHF (r=0.4, p <0.05). The thickness of the EAT in the general group was directly correlated with the presence of risk factors for cardiovascular diseases (CVD) (r=0.3, p <0.05), as well as with the presence of hypertension (r=0.4, p <0.05) and systolic blood pressure (SBP) (r=0.2, p <0.05), the presence of complaints of shortness of breath (r=0.3, p <0.05) and edema on objective examination (r=0.3, p <0.05). This correlation was even more strongly demonstrated in the group of patients with CHF with the presence of CVD risk factors (r=0.5, p <0.05) and hypertension (r=0.7, p <0.05) and the presence of edema (r=0.4, p <0.05), while no correlating with the level of SBP and shortness of breath was found.
Conclusion: in patients with high-activity rheumatoid arthritis, correlations were found with the thickness of the EAT with clinical parameters and with the presence of one or more risk factors for CVD. In the group with CHF, there is an additional correlation of EAT with the presence of edema. Patients with CHF pre-stage had no correlation with EAT.

P255

EFFECTIVENESS OF REMS TECHNOLOGY FOR SHORT-TERM MONITORING OF ROMOSOZUMAB EFFECT AT THE FEMORAL SITE IN POSTMENOPAUSAL WOMEN

A. Semeraro[1], A. Chialà[1], A. Carafa[1], R. Fanizzi[2], E. Di Tano[1], M. Palmisano[1], C. Santoro[1], F. Dibenedetto[1], N. Napoli[2]

[1]U.O.S. Reumatologia "P.O. Valle D'Itria", Martina Franca, ASL – Taranto., Martina Franca, Italy; [2]U.O.C. Medicina Generale "P.O. Valle D'Itria", Martina Franca, ASL –, Martina Franca, Italy

Objective(s): Romosozumab (RMZ) is a humanized monoclonal IgG2 antibody that selectively inhibits sclerostin, exerting a unique dual mechanism of action by stimulating bone formation and reducing bone resorption. This retrospective observational study aimed, for the first time, to evaluate the effectiveness of Radiofrequency Echographic Multi Spectrometry (REMS) for short-term monitoring of RMZ treatment in a cohort of post-menopausal women.

Materials and Methods: Post-menopausal women eligible for RMZ therapy were enrolled and monitored before (baseline) and at six-months (T1) follow-up. All the patients underwent REMS scans at the femoral site at both time-points to assess bone mineral density (BMD), T-score and Fragility Score (FS) values. Changes over time were analyzed using paired *t*-tests. Analyses were stratified by key variables (e.g., age group, BMI, prior osteoporosis therapy, number of vertebral fractures) to assess potential heterogeneity of treatment effects.

Results: A total of $n = 27$ patients (mean age: 71.7 ± 7.3 years) completed the six-months follow-up and were included in the analysis. At T1 a statistically significant increase in BMD was observed compared with baseline, with a 3.0% increase at the total hip (0.725 ± 0.103 g/cm² *vs*. 0.704 ± 0.108 g/cm²; $p = 0.004$) and a 2.7% increase at the femoral neck (0.573 ± 0.085 g/cm² *vs*. 0.558 ± 0.091 g/cm²; $p = 0.006$).

Conclusion(s): This retrospective observational study demonstrates, for the first time, the effectiveness of REMS technology in monitoring the short-term effects of RMZ in post-menopausal women, confirming the findings reported in the literature using standard densitometric technologies such as dual energy X-ray absorptiometry (DXA). Overall, thanks to its radiation-free nature, high-precision, high-portability and low-costs, REMS appears to be a valuable tool for assessing the real-world short-term clinical effectiveness of RMZ therapy.

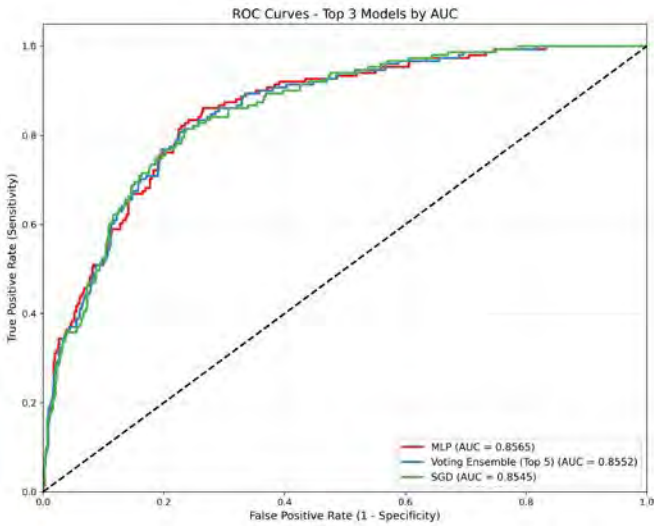
Objective: To develop and validate a high-sensitivity machine learning screening tool for sarcopenia using routine clinical variables, optimized to minimize false negatives.

Material and Methods: We analyzed data from 4,110 older adults in the Bushehr elderly health program, defining sarcopenia using EWGSOP2 criteria. Recursive feature elimination using regularized logistic regression and XGBoost identified top predictors. Twelve base classifiers and three ensembles were trained on the training set (80%) using SMOTEENN resampling. Decision thresholds were dynamically tuned via internal cross-validation to maximize the F2-score, with validation on a 20% independent test set. Model performance was evaluated using AUC, sensitivity, specificity, and F2-score.

Results: The cohort (median age 66.0 years, 54.2% female) showed 18.4% sarcopenia prevalence. The multilayer perceptron (MLP) was the optimal screening model, achieving the highest discriminatory power (AUC 0.86, sensitivity 0.89, specificity 0.66, F2 0.70) and a negative predictive value of 0.97, validating its utility for rapid triage (Table and Figure). Voting ensemble yielded comparable performance (AUC 0.86, sensitivity 0.86), while the stacking ensemble maximized specificity (0.72) at the cost of sensitivity (0.80). MLP superiority suggests non-linear interactions between predictors (Table).



Conclusion: This sensitivity-optimized MLP classifier utilizing routine metrics effectively screens for sarcopenia. By prioritizing false-negative reduction, the framework facilitates risk stratification and timely intervention. An online risk calculator was developed based on these models.

OPTIMIZING OSTEOSARCOPENIA SCREENING: DIRECT VERSUS COMBINED MACHINE LEARNING APPROACHES IN COMMUNITY-DWELLING OLDER ADULTS

S. Forghani[1], A. Shahsavand[1], A. Dadras[2], S. Nayebirad[3], A. Razi[4], K. Khalagi[1,5], N. Fahimfar[1,6], G. Shafiee[7], M. Sanjari[1], I. Nabipour[8], B. Larijani[9], H. Kavoosi[10]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Department of Computer Engineering, Sharif University of Technology, Tehran, Iran, Tehran, Iran; [3]Tehran Heart Center, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [5]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [6]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [7]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [8]The Persian Gulf Marine Biotechnology Research Center, the Persian Gulf Biomedical Sciences Research Institute, Bushehr University of Medical Sciences, Bushehr, Iran, Tehran, Iran; [9]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [10]Rheumatology Research Center, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: To evaluate machine learning models for osteosarcopenia screening by comparing direct classification against a combined framework of low bone mass and sarcopenia models.

Material and methods: We analyzed baseline data of 4,110 older adults from the Bushehr elderly health program, defining osteosarcopenia as coexistent sarcopenia (EWGSOP2) and low bone mass (DXA T-score < -1.0). The study compared direct joint classification versus a combined approach using a stacking meta-learner to aggregate calibrated classifiers. Following an 80/20 stratified split, we employed hybrid feature selection (recursive feature elimination with cross-validation) and SMOTEENN resampling to address class imbalance. Classification thresholds were F2-optimized via 5-fold cross-validation with isotonic calibration. We used AUC, sensitivity, specificity, and F2-score to measure model performance.

Results: Among participants (median age 66.0; 54.2% female), the prevalence of osteosarcopenia was 17.1%. Feature selection prioritized anthropometrics, comorbidities, and functional metrics as key predictors (Table). The direct extra trees model achieved acceptable screening metrics (AUC 0.84, sensitivity 0.87, specificity 0.66, F2 0.67). The Combined framework (XGBoost/balanced stacking) enhanced sensitivity (0.89) while maintaining comparable predictive performance (AUC 0.84, specificity 0.65, F2 0.67). Alternatively, an extra trees/multilayer perceptron configuration offered higher specificity (0.73) with slightly reduced sensitivity (0.83).

Conclusion: Accounting for the joint probability of bone and muscle health yields higher sensitivity than direct classification. This strategy allows for context-specific model selection and supports a tiered screening protocol, triaging high-risk individuals for confirmatory DXA to ensure timely intervention. These models are available as a web-based risk assessment tool.

https://osteosarcopenia-risk-calculator-u9pvs4ecg7euxryfcec3mc.streamlit.app/

Table: Performance of the top six models for osteosarcopenia screening using 18 features.

Model	F2	Sensitivity	Specificity	AUC
Extra Trees (Direct)	0.668	0.872	0.656	0.838
MLP (Direct)	0.667	0.865	0.664	0.847
Random Forest (Direct)	0.662	0.872	0.645	0.839
Extra Trees + MLP	0.674	0.830	0.725	0.841
Balanced Stacking + MLP	0.674	0.830	0.725	0.841
Random Forest + Extra Trees 0.674 0.872 0.668 0.841				
Feature importance: weight, sex, hormone replacement therapy, age, forearm circumference, chronic renal failure, parity, difficulty climbing stairs, diabetes, waist circumference, fear of falling, difficulty walking, smoking status, fracture cause, difficulty lifting, height, MNA score, thigh circumference.

ONE-YEAR THROMBOEMBOLIC RISK FOLLOWING FRACTURES IN ADULTS AGED ≥50 YEARS: RESULTS FROM A NATIONWIDE RETROSPECTIVE COHORT

A. Sokhan[1,2], M. Behanova[1,2], S. Slavic[1,2,3], J. Haschka[1], J. Zwerina[1], R. Kocijan[1,2]

[1]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of OEGK and AUVA Trauma Centre Meidling, 1st Medical Department, Vienna, Austria; [2]Sigmund Freud University Vienna, School of Medicine, Metabolic Bone Diseases Unit, Vienna, Austria; [3]Health Care Centre Mariahilf, OEGK, Vienna, Austria, Vienna, Austria

Objectives

Numerous studies based on the inpatient treatment period have demonstrated an increased risk of thromboembolic and hemorrhagic vascular events (THVEs) after fractures, especially in elderly patients. However, the epidemiology of THVEs after hospital discharge, particularly population-level estimates by fracture type, remains unknown.

Material and Methods

We conducted a nationwide retrospective register-based study using pseudonymised inpatient data obtained from Austrian social insurance authorities and the Federal Ministry of Labour, Social Affairs, Health, and Consumer Protection. We included all patients in Austria ≥50 years hospitalised with any kind of fracture (2016-2020). Thrombotic and bleeding diagnoses were grouped as THVEs. We estimated the 1-year cumulative incidence function (CIF) using competing risk methodology, with death as a competing event.

Results

We analysed a cohort of patients who sustained any type of fracture (N=102,941; mean age 75.5, SD 12.1; females 69.8%) and who had not been hospitalized due to THVEs before fracture. Within this cohort, 4857 (4.7%) patients experienced a THVE.

Using competing risks analysis with death as a competing event (11,047 deaths, 10.7%), the 1-year cumulative incidence of THVE was 2.73% (95% CI: 2.63%-2.83%). Stratification by fracture type revealed significant heterogeneity (Gray's test p<0.001): femur and lumbar/pelvis fractures had the highest risk (3.3%), while forearm fractures had the lowest (1.2%). This variation strongly correlated with patient age, as femur fracture patients were oldest (mean age 80.2 years) and forearm fracture patients youngest (67.7 years).

Cerebral infarction was the most common (1,427 events, 1-year CIF: 0.78%, 95% CI 0.72-0.83), followed by pulmonary embolism (627 events, 0.40%, 95% CI 0.36-0.44) and myocardial infarction (681 events, 0.35%, 95% CI 0.31-0.39). Increasing age was associated with higher THVEs risk (SHR = 1.039 per year, 95% CI 1.036–1.043, p < 0.001), while females had significantly lower risk compared to males (SHR = 0.799, 95% CI 0.737–0.867, p < 0.001).

Conclusion

THVEs risk after fracture is substantial but varies significantly by fracture type and patient age. These findings support fracture-specific and age-stratified approaches to long-term prophylaxis rather than uniform protocols. The competing risk of death far exceeds THVEs risk, emphasizing the importance of appropriate statistical methods.

P259

A REAL-WORLD INVESTIGATION OF ROMOSOZUMAB IN EUROPEAN CLINICAL PRACTICE: DESIGN AND RATIONALE OF THE PRIME STUDY

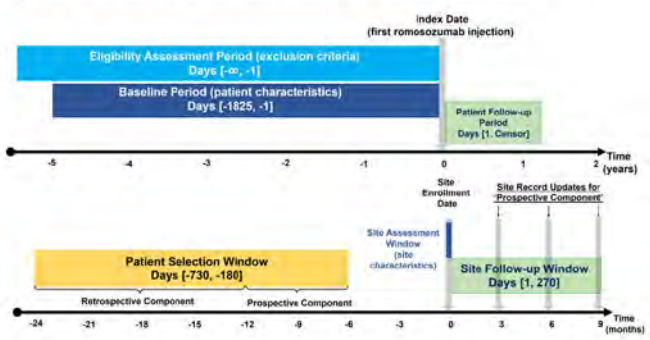
A. Moayerri[1], M. Langlois[2], P. Öhagen[3], A. Spångeus[4,5], N. Napoli[6], O. Sahota[7], E. Toniolo[8]

[1]UCB, Slough, United Kingdom; [2]UCB, Paris, France; [3]UCB, Uppsala, Sweden; [4]Linköping University Hospital, Linköping , Sweden; [5]Linköping University, Linköping, Sweden; [6]Fondazione Policlinico Universitario Campus Bio-Medic Roma, Rome, Italy; [7]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [8]UCB, Madrid, Spain

Objective: Romosozumab (Romo) is a dual-effect sclerostin inhibitor indicated for postmenopausal women with severe osteoporosis at high fracture risk. PRIME (Prospective Romosozumab Investigation in Multiple European countries) is an ambispective (retrospective and prospective), real-world evidence (RWE) study to describe patient characteristics, treatment patterns, transition to antiresorptive therapy and Romo persistence across 8 European countries. Secondary objectives are to identify persistence predictors and assess site and patient characteristics by country.

Materials/Methods: Patients will be recruited from Belgium, Germany, Greece, Italy, Spain, Sweden, Switzerland and the UK (**Figure**). Data collection at 3 levels began in April 2025:

- Patient: demographics, comorbidities, fracture/treatment history and bone health before/after Romo initiation
- Site: characteristics, prescribing practices and local protocols
- Country: guidelines and reimbursement policies



Eligible patients received their first Romo dose 24–26 months before enrolment; recruited participants are followed for 9 months. Incorporating retrospective data on participants who discontinued or completed a 12month Romo course prior to enrolment, and prospective data, enables inclusion of more patients with complete 12-month follow-up. Extending follow-up by 3 months supports assessment of antiresorptive

transitions. Exclusion criteria included recent enrolment in osteoporosis clinical trials. Persistence and adherence will be measured by proportion of days covered in a year, discontinuation rates and Romo completion. Persistence predictors will be analysed using Cox and logistic regression; subgroup and sensitivity analyses are planned.

Results: The expected study completion date is September 2026. As of November 2025, 99 sites have enrolled from all 8 countries; expected final sample size is 3,500 patients from 120 sites.

Conclusion: The design of PRIME differentiates it from other RWE studies, capturing the most recent clinical practice across Europe. By integrating multi-level data, PRIME will offer a broad, nuanced understanding of current Romo prescribing and utilisation patterns.

IDENTIFYING HIGH-RISK SUBGROUPS FOR OSTEOPOROSIS IN TYROL NURSING HOMES: PULSE-ECHO ULTRASOUND COMBINED WITH FRAX

A. Stegmayr[1], H. M. Preuer[1], M. Prokopetz[1], N. Mach[1]

[1]Health University of Applied Sciences Tyrol, Innsbruck, Austria

Objective(s)

Osteoporosis is the most common disorder of bone metabolism and often remains undetected until a fragility fracture occurs. Austria has one of the highest incidences of osteoporotic fractures worldwide. Older adults living in nursing homes (NH) are particularly vulnerable, yet access to standard bone mineral density assessment may be limited in long-term care. This study aimed to assess osteoporosis probability among nursing home residents in Tyrol (Western Austria) using an accessible diagnostic alternative.

Material and Methods

A cross-sectional study was conducted including 235 nursing home residents aged ≥50 years in Tyrol. Participants were examined in two settings: urban and rural nursing home residents. Exclusion criteria were age <50 years, prior knee surgery or prosthesis, allergy to ultrasound gel, and pregnancy. Anthropometric data were collected, and osteoporosis probability was assessed using pulse-echo ultrasound combined with FRAX. Measurements were performed by trained radiographers and validated by a physician. Statistical analyses were adjusted for age, gender, living situation (urban/rural) and body mass index (BMI).

Results

A point-of-care approach combining pulse-echo ultrasound - based assessment of bone density with FRAX enabled rapid and efficient screening of nursing home residents. Consistent with previous studies, osteoporosis probability was higher in women than in men and increased markedly with age. The highest-risk subgroup was comprised women aged over 70 years with low BMI, identifying them as the most vulnerable population. Our preliminary data also showed that 28% of men had a high osteoporosis risk and 13% had a medium risk, highlighting that male nursing home residents also exhibit a clinically relevant osteoporosis risk.

Conclusion(s)

Pulse-echo ultrasound combined with FRAX identified a substantial burden of elevated osteoporosis probability among nursing home residents, particularly in older women with low BMI. Practical screening approaches may help prioritize high-risk individuals for further evaluation and timely osteoporosis management in long-term care.

Objectives:

Recently, initial use of osteoanabolic agents is recommended in goal-

directed treatment algorithms for patients at very high fracture risk (VHFR). Although FLS and Osteoporosis Liaison Service (OLS) have been established to improve the osteoporosis management, the effectiveness of these intensive care programs which integrate osteoanabolic therapies has not been established. We designed a clinical trial to investigate the effectiveness of intensive care (FLS-CARE) aligned with the goal-directed osteoporosis treatment compared with usual care in patients at VHFR.

Methods and Analysis:

Japanese Osteoporosis Intervention Trial-08 (JOINT-08), a multi-center, site classification into two groups, on-going intervention study, involves postmenopausal Japanese women at VHFR aged 55 and older, defined by any of: bone mineral density (BMD) T-score < -3.3, two or more prevalent vertebral fractures, at least one semi-quantitative (SQ) grade 3, one or more fragility fractures with BMD T-score < -2.5, or a prevalent hip fragility fracture.

The patients in FLS-CARE group are registered at medical institutions with a Japan Osteoporosis Society-certified physician and OLS manager and receive an intensive care program integrating goal-directed osteoporosis treatment and FLS/OLS support (education on osteoporosis and treatment management). Patients in the control (PCP-CARE) group receive standard care at the discretion of their primary care physician.

The primary endpoint of this study is the incidence of morphometric vertebral fractures by SQ grade at 12 months, and the key secondary endpoint is the incidence of morphometric vertebral fractures at 24 months. The other secondary end points are adherence, persistence, incidence of non-vertebral fractures, incidence of worsening of vertebral fracture by SQ grade, changes in BMD at lumbar spine, femoral neck, and total hip at 12 months as well as descriptive analyses of adverse events.

Conclusion:

JOINT-08 is the first study to investigate the effectiveness of an intensive care program, combining goal-directed osteoporosis treatment and patient management by an OLS manager in postmenopausal osteoporosis at VHFR. The findings will be crucial for advancing treatment strategies to prevent osteoporotic fractures.

P262

BEFORE THE FALL: BALANCE PROBLEMS AND BONE DENSITY IN POSTMENOPAUSAL WOMEN

A. T. Canbulat[1], [2]

[1]Gulhane Training and Research Hospital, Ankara, Türkiye; [2]

Introduction Postmenopausal osteoporosis is commonly viewed in the context of reduced bone mineral density and the consequent risk of fractures. However, falls play a central role in the occurrence of osteoporotic fractures, and balance-related complaints such as unsteadiness and staggering often emerge before an actual fall event. In addition to biological determinants, fall risk may also be influenced by living conditions and the level of social support. In this respect, balance problems may be more pronounced among postmenopausal women who live alone.

Objective The aim of this study was to explore the relationship between bone mineral density and balance-related symptoms, including staggering and falls, in postmenopausal women, and to assess whether living alone may modify this association.

Methods This cross-sectional observational study included postmenopausal women attending a physical medicine and rehabilitation outpatient clinic who had undergone bone mineral density assessment within the preceding six months. Bone mineral density measurements of the lumbar spine and femoral neck were recorded, and the lowest T-score for each participant was used for analysis.

Information on staggering and falls during the previous one month and one year was obtained by self-report. Living arrangements (living alone or with family/caregivers) were recorded and considered an indicator of social vulnerability.

Based on balance-related clinical features, participants were categorized into three groups: asymptomatic individuals, those reporting staggering without recent falls (pre-fall instability), and those with a history of falls. Bone mineral density values were compared across groups, with additional analyses stratified by age (<65 and ≥65 years). The study was conducted as an exploratory analysis including a total of 75 participants, and statistical significance was set at $p<0.05$.

Table 1. Demographic and Clinical Characteristics According to Clinical Phenotypes

	Asymptomatic (n=25)	Pre-fall Instability (n=25)	Fall Group (n=25)	p value
Age (years)	61.8 ± 7.9	66.4 ± 6.8	70.2 ± 6.1	0.001
Height (cm)	152.6 ± 4.8	152.1 ± 4.5	151.9 ± 5.2	0.73
Weight (kg)	77.1 ± 12.6	71.8 ± 11.9	67.4 ± 10.8	0.018
Body Mass Index (kg/m²)	33.1 ± 5.2	30.4 ± 4.9	28.9 ± 4.6	0.012
Menopause duration (years)	15.9 ± 8.7	21.8 ± 9.1	25.6 ± 8.4	<0.001
Bone Mineral Density (g/cm²)	0.852 ± 0.121	0.744 ± 0.108	0.682 ± 0.094	<0.001
Lowest T-score −1.8 ± 0.6 −2.3 ± 0.5 −2.7 ± 0.4 <0.001				
Smoking – Yes	2 (8.0%)	4 (16.0%)	5 (20.0%)	0.42
Alcohol use – Yes	1 (4.0%)	1 (4.0%)	2 (8.0%)	0.78
Menopause type – Natural	22 (88.0%)	21 (84.0%)	20 (80.0%)	0.74
Living alone – Yes	2 (8.0%)	7 (28.0%)	9 (36.0%)	**0.021**

Table 2. Frequency of Staggering and Falls According to Clinical Phenotypes

	Asymptomatic n (%)	Pre-fall Instability n (%)	Fall Group n (%)	p value
Staggering in the past 1 month – Yes	3 (12.0%)	18 (72.0%)	20 (80.0%)	<0.001
Staggering in the past 1 year – Yes	6 (24.0%)	21 (84.0%)	23 (92.0%)	<0.001
Falls in the past 1 month – Yes	2 (8.0%)	0 (0.0%)	9 (36.0%)	**0.004**
Falls in the past 1 year – Yes	5 (20.0%)	4 (16.0%)	14 (56.0%)	0.006

Conclusion The findings of this study indicate that lower bone mineral density in postmenopausal women is associated with balance-related problems and an increased risk of falls. Balance disturbances occurring in the absence of a fall may represent an early stage of vulnerability preceding fall events. In addition to biological factors, social conditions such as living alone should also be considered when evaluating fall risk in this population.

P263

IDENTIFYING GAPS IN OSTEOPOROSIS MANAGEMENT: A CLINICAL AUDIT IN A MULTIDISCIPLINARY FACILITY

A. Tarasova[1]

[1]Osteoporosis and fractures prevention foundation, Moscow, Russia

Objective:
To assess the adherence to osteoporosis screening, diagnosis, and management national guidelines in a multidisciplinary clinical setting, and to identify specific gaps in physician knowledge and real-life clinical practice.

Material and Methods:
A mixed-methods internal audit in a multidisciplinary clinic was conducted. A knowledge and practice survey was distributed to 64 physicians across eight specialties. A retrospective review of 100 clinical records (general practitioners, endocrinologists, gynaecologists, rheumatologists, traumatologists) was focused on patients meeting age/risk criteria for osteoporosis. An additional review of 20 routine chest/abdominal imaging studies (CT/MRI) was performed to assess the reporting of incidental vertebral fractures. Data extraction was focused on fracture history documentation, FRAX tool utilisation, Dual-Energy X-ray Absorptiometry (DXA) referrals, diagnosis coding, and treatment initiation for fragility fractures and high-risk patients.

Results:
The survey response rate was 26.6% (17/64). While all respondents acknowledged the importance of osteoporosis, only 23% correctly identified all risk factors relevant to their specialty. Understanding of low-energy fractures was inconsistent. Clinical record analysis revealed significant practice gaps: among 14 eligible general practitioner records, only 3 (7.5%) resulted in a DXA referral, with no FRAX assessments performed. Only one endocrinologist routinely used the FRAX tool in his daily practice. None of 5 patients with diabetes mellitus had a FRAX assessment; overall, 12 of 20 endocrine patients underwent or were referred for DXA. Gynaecologists demonstrated no engagement in osteoporosis screening for postmenopausal women. Rheumatologists initiated treatment for only 2 out of 6 potentially eligible patients. Review of 20 imaging studies identified 8 cases of vertebral height loss (21-34%), yet this was reported as a potential fracture in only 2 cases. Among 11 patients with low-energy fractures identified in traumatology department, only 4 were referred to a specialist; osteoporosis was not diagnosed in any of these cases, neither the treatment was recommended. Patients' fracture history in medical records was unclear in most cases as the obstacles of trauma (low/high energy) if it was depicted.

Conclusion:
This audit reveals critical systemic gaps in osteoporosis care, including underutilisation of risk assessment tools (FRAX), low engagement in osteoporosis care by primary care and gynaecologists, poor management of fragility fractures, and under-reporting of vertebral fractures on imaging. These findings highlight an urgent need for targeted education, standardised referral pathways, and improved interdisciplinary coordination to enhance secondary fracture prevention.

P264

IMPROVED NEUTROPHILS ISOLATION TECHNIQUE FOR INVESTIGATION OF NEUTROPHIL EXTRACELLULAR TRAPS

A. Trofimenko[1], M. Mamus[1], E. Mozgovaya[1], S. Bedina[1], S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Background: Neutrophils are involved in the pathogenesis of various infections, COVID-19, as well as atherosclerosis, thrombosis and embolism, cancer and rheumatic diseases, being an important element of the normal immune response. In this regard, mechanisms of mobilization, activation, apoptosis and formation of neutrophil extracellular traps (NETs) by neutrophils are of a great concern for many years. The major technical obstacle for assessment of functional state of neutrophils is the lack of an accepee method for isolation a pure cell fraction that does not contain a significant amount of non-viable or activated neutrophils.

Methods. Blood samples were obtained from 29 healthy volunteers. Circulating neutrophils of peripheral blood were isolated from buffy coat using both stepwise iohexol density gradient with 1080 and 1090 kg/m3 densities as well as control ficoll-amidotrizoate based gradient consisted of 1077 and 1119 kg/m3 steps (Sigma-Aldrich, USA). These protocols were compared by fraction purity (using microscopy of a stained smear), cell viability (by trypan blue staining), and cell activation (by nitroblue tetrazolium test). Induction of NET formation was performed using phorbol myristate acetate (50 nmol/l). Both spontaneous and induced NETs were visualized by fluorescence microscopy using 1.25 μM SYBR green and monoclonal antibodies to myeloperoxidase labeled with R-phycoerythrin. Results are expressed as means and 95% confidence intervals (M (95%CI)). Differences were considered significant at $p<0.05$.

Results. When comparing the characteristics of the neutrophil fraction isolated by our method with the control, higher values of neutrophil fraction purity were noted. The method we developed allowed us to isolate neutrophils with a higher viability percentage (84.74 (83.99-85.49)% and 76.84 (75.32-78.36)%, respectively) and a lower percentage of activated cells (13.10 (12.92-13.28)% and 15.36 (15.00-15.72)%, respectively). The differences in the mean values of viability and the percentage of activated cells were statistically significant ($p<0.001$). In addition, in our experiments, the iohexol-based gradient was characterized by greater stability during storage, ease of sterilization, constant isoosmolarity, and the absence of ficoll adhesion to the cells. The average proportion of spontaneous NET formation for the iohexol-containing gradient was 3.8 (2.6-5.0)%, for the control gradient - 7.9 (7.0-8.8)%; for PMA-induced NET formation - 12.2 (9.0-15.4)% and 15.3 (13.6-17.0)%, respectively.

Conclusion. The method we developed provides an increased proportion of viable and inactivated neutrophils compared to the prototype and can be used for a detailed study of neutrophils in various infectious diseases. In addition, iohexol allows to obtain easily the required density of the medium, maintaining its physiological osmolarity. The insignificance of the activating effect of the modified gradient on neutrophils is due to the absence of components adhering to cells in its composition, which also determines the preservation of the tinctorial properties of cells after passing through iohexol-containing gradients. There was significant effect of the choice of the isolation protocol on the intensity of NET formation.

P266

CURRENT PRACTICE AND BARRIERS IN FRAGILITY HIP FRACTURE MANAGEMENT: INSIGHTS FROM A NATIONAL SURVEY OF THAI ORTHOPAEDIC SURGEONS

B. Jinlawal[1], P. Chotiyarnwong[1], E. Vanitcharoenkul[1], N. Adulkasem[1], A. Unnanuntana[1]

[1]Department of Orthopaedic Surgery, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objective

Despite well-established recommendations for the treatment and secondary prevention of fragility fractures, implementation remains challenging. Understanding local practice realities and barriers is therefore essential for adapting global guidelines to national health systems. This study assessed the management of fragility hip fractures in elderly patients in Thailand, focusing on the perspectives of orthopaedic surgeons.

Material and Methods

We conducted a questionnaire-based survey of orthopaedic surgeons in Thailand who are actively involved in the care of patients with fragility fractures, focusing on acute management, secondary prevention, and overall perceptions of care. The survey was adapted and translated from the "Survey of Awareness and Attitudes to the Management of Fragility Fractures" developed by the Asia Pacific Orthopaedic Association. It was piloted with 10 volunteer orthopaedic surgeons and refined for clarity, comprehensiveness, and validity. The final questionnaire was distributed online in collaboration with the Royal College of Orthopaedic Surgeons of Thailand using registered membership contacts.

Results

Of 223 responses, 199 were eligible. Most participants practiced in tertiary public hospitals (36.2%), had <5 years of experience, and managed 0–5 cases weekly. According to respondents, hip fracture fast-track protocols were available in 79.4% of hospitals, and 58.8% had fracture liaison services. Only 22.6% of respondents reported achieving surgery within 48 hours in > 90% of their patients, and 46.7% prescribed osteoporosis treatment to ≥75% of patients. University-affiliated hospitals were more likely to prescribe osteoporosis medication (OR 4.68, 95% CI 1.87–11.67), while cost concerns reduced prescribing (OR 0.40, 95% CI 0.20–0.81). Private hospitals had the highest odds of surgery within 48 hours (OR 104.43, 95% CI 7.21–1513.05). Implant unavailability was the main barrier to expedited surgery (OR 0.20, 95% CI 0.04–0.91).

Conclusions

Although hip fracture fast-track protocols and fracture liaison services are increasingly available, timely surgery and osteoporosis treatment remain suboptimal. Addressing cost barriers, improving implant logistics, and expanding diagnostic access are essential to strengthen fragility fracture care in Thailand.

P267

FACTORS INFLUENCING THE DEVELOPMENT OF CHRONIC POSTOPERATIVE PAIN AFTER LARGE JOINT REPLACEMENT IN RHEUMATOID ARTHRITIS

V. N. Khlaboshchina[1], A. V. Bobkova[1], E. Y. U. Polishchuk[1], V. A. Nesterenko[1], V. E. Byalik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the effect of a number of clinical and psychological factors on the persistence of chronic postoperative pain for one year after hip and knee replacement in patients with rheumatoid arthritis.

Material and Methods: The study consistently included patients with rheumatoid arthritis who were admitted to the rheumoorthopaedic department from May 2022 to May 2024 for routine total knee/hip replacement. All patients were examined by a rheumatologist before surgery with an assessment of the disease activity according to DAS28-CRP, and were also asked to fill out the following questionnaires: Health Assessment Questionnaire (HAQ), painDETECT, Hospital Anxiety and Depression Scale (HADS), Pain Catastrophizing Scale.

Results: A total of 350 patients were recruited, 279 women (79.7%) and 71 men (20.3 %) The average age was 57.2±14.1 years, the average duration of the disease was 14.9±10.8 years. The age of onset (Me [25‰;75‰] was 45 [29;55] years. The majority of patients had the stage II or III according to the Steinbroker's classification (44.5% and 35.9%, respectively). 20.3% showed signs of osteonecrosis. On average, signs of moderate disease activity were observed before surgery (DAS28-CRP was 3.6±1.1). 82.9% and 26.4% of patients received and conventional and biological disease-modifying antirheumatic drugs, respectively. After 12 months, 17.1% of patients continued to complain of pain in the area of the operated joint in the absence of infection or instability of the prosthesis components. The likelihood of pain retention correlated with the following factors ($p < 0.05$): female gender, depression or high anxiety according to HADS, high disease activity (DAS28-CRP≥5.1), neuropathic component of pain(painDETECT>18), a tendency to catastrophize pain (PCS>21), signs of central sensitization (CSI>40). Protective factors were methotrexate intake and low disease activity. Patients who underwent total arthroplasty for aseptic necrosis were significantly less likely to suffer from chronic postoperative pain.

Conclusion: Factors such as female gender, the presence of neuropathic pain, depression/anxiety, and a tendency to catastrophize pain can contribute to the persistence of chronic pain in patients with rheumatoid arthritis after total knee and hip arthroplasty.Methotrexate intake and low disease activity before surgery had a protective effect.

P268

ASSESSMENT OF FACTORS INFLUENCING FUNCTIONAL OUTCOME AFTER TOTAL KNEE REPLACEMENT IN RHEUMATOID ARTHRITIS

V. N. Khlaboshchina[1], A. V. Bobkova[1], E. Y. U. Polishchuk[1], V. A. Nesterenko[1], V. E. Byalik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the effect of a number of clinical factors on the functional status for one year after knee replacement inpatients with rheumatoid arthritis.
Material and Methods: The study consistently included patients with rheumatoid arthritis who were admitted for routine total knee replacement. All patients were examined by a rheumatologist before surgery with an assessment of clinical and pharmacological history and the disease activity according to DAS28-CRP. Knee joint function before and 12 months after surgery was assessed using the Knee Society Score (KSS). Patients were also asked to fill Health Assessment Questionnaire (HAQ) before surgery.
Results: A total of 221 patients were recruited (173 women (78.2%); the average age 55.8±13.9 years). Before surgery the average value of DAS28-CRP was 3.9±1.2, HAQ - 1,5±0,6. The KSS function averaged 48.3±16.4 before TKA and 86.0±7.7 12 months after TKA. The number of patients with KSS levels <70 (unsatisfactory) at the end of the cohort follow-up was only 12 (5.4%). Insufficient functional outcome was associated with moderate/high inflammatory activity at the time of surgery(p=0.023), initially pronounced functional disorders (HAQ>2, p=0.049), and the use of leflunomide (p=0.005). There was no clear relationship between the development of postoperative pain after12 months and the presence of an insufficient functional result (OR = 1.263 [95% CI 0.347-4.59] p=0.527).
Conclusion: The presence of signs of inflammatory activity, pronounced functional disorders, as well as taking leflunomide may contribute to an unsatisfactory functional outcome after total knee arthroplasty in rheumatoid arthritis. Further researchis required to clarify the data obtained.

P269

POLYMORPHISMS OF THE KCNS1, COMT, IL6R AND CTLA4 GENES AND DEVELOPMENT OF POSTOPERATIVE PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT TOTAL KNEE OR HIP REPLACEMENT

V. N. Khlaboshchina[1], I. A. Guseva[1], A. V. Bobkova[1], E. Y. U. Polishchuk[1], V. A. Nesterenko[1], V. E. Byalik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to assessing relationship of the polymorphisms of the KCNS1, COMT, IL6R and CTLA4 genes and the development of postoperative pain (POP) in rheumatoid arthritis (RA)patients who underwent total knee (TKA) or total hip (THA) arthroplasty.
Material and methods: The study group consisted of 85patients with RA knee or hip (79.7% of women, 57.2±13.1years) who underwent TKA or THA. The presence of POP was determined when pain in the area of surgical intervention ≥40 mm (100 mm visual analog scale, VAS) persisted or appeared 12 months after surgery. All patients underwent genotyping of polymorphisms of the genes KCNS1 (rs734784), COMT (rs4633), IL6R (rs8192284) and CTLA4 (rs231775) by polymerase chain reaction in real time using original sequence-specific primers and samples labeled with various fluorescent labels. Registration and interpretation of the obtained results were carried out on the DT-96 amplifier (DNA-Technology LLC, Russia).
Results: POP was observed in 30.6% of patients who underwent TKA or THA. Statistical analysis revealed no differences in the frequencies of the genotypes of the studied genes (p>0,05). The presence of a homozygous genotype of the GG polymorphism of the KCNS1 gene (rs734784) was associated with the presence of POP in accordance with the recessive genetic model (GG vs AA+AG; odds ratio (OR) – 18.67 [95% confidence interval (CI): 4.64; 75/16]; p<0.001). The presence of at least one C allele in the genotype of the COMT polymorphism (rs4633) was associated with a pronounced tendency to increase the risk of developing POP compared with the TT genotype (OR=2.83[95% CI: 0.81; 9.97]; p=0.06) in accordance with the dominant genetic model. The multiplicative model (T vs C) turned out to be statistically significant (OR=2.21 [95% CI: 1.08; 4.54]; p=0.06). In the study of CTLA4 gene polymorphism (rs231775), carriers of at least one minor G (AG+GG) allele had a lower risk of developing POP compared with AA genotype (OR=0.27[95% CI: 0.09; 0.80]; p=0.01). There was no significant correlation between the development of POP and the carrier of different genotypes and alleles of the IL6R (rs8192284) gene.
Conclusions: There is a statistically significant association the polymorphism of the KCNS1 (rs734784) and COMT (rs4633) genes and the development of chronic POP in patients who underwent TKA or THA. Carriage of the minor allele of the CTLA4 (rs231775) gene had a protective effect. Further studies of the genetic predisposition to POP are required on more clinical material.

P270

CLINICAL FEATURES OF HAND OSTEOARTHRITIS IN WOMEN WITH DIFFERENT BODY MASS INDEXES IN POSTMENOPAUSE

A. V. Tyurin[1], I. I. Galina[1]

[1]Bashkir State Medical University, Ufa, Russia

Study objective. To evaluate the characteristics of hand osteoarthritis in postmenopausal women with varying body weight and bone density.

Materials and methods. A cross-sectional study of 122 postmenopausal women was conducted. The study group included 80 patients with hand osteoarthritis (60 ± 5 years old), and the control group included 42 women without joint pathology (57 ± 4 years old). The diagnosis of hand osteoarthritis was verified according to the EULAR criteria (2023) and confirmed radiographically. Exclusion criteria included diabetes mellitus, systemic inflammatory connective tissue diseases, upper extremity injuries, acute infectious processes, heart failure, chronic kidney disease stages 4–5, as well as professions and hobbies that place increased stress on hand joints. All study participants completed a questionnaire, dynamometry, and body composition assessment using dual-energy X-ray densitometry at standard points and in "total body" mode.

Results. The median AUSCAN index was higher in women with normal body weight (16 [12; 24.5]) compared to the overweight and obese groups (15 [9.5; 26.5] and 12.5 [9; 20.75], respectively); however, the differences did not reach statistical significance. Obese patients had higher lumbar

spine T-score values than normal-weight patients (−0.32 ± 2.00 and −1.73 ± 1.64; p = 0.01). In patients with osteoarthritis and osteoporosis combined, more pronounced functional impairment, significant limitations in daily activities, and a lower total body fat percentage were observed (38.84 ± 6.35% and 43.03 ± 6.73%; p = 0.0013).

Conclusion: In postmenopausal women with hand osteoarthritis, decreased muscle strength and functional impairment are exacerbated by the combination of osteoporosis. Body mass index is positively associated with bone mineral density but is associated with decreased muscle strength, highlighting the need for a comprehensive body composition assessment.

P271

INTRIGUING STATISTICS OF OSTEOPOROSIS AMONG MENOPAUSAL WOMEN IN THE ADJARA REGION

N. Tsintsadze[1,2,3,4], A. Verdzadze[1], T. Salvaridze[2,4], N. Kakabadze[1,2], A. K. Kushwaha[1], M. Saddala[1], S. Maghlakelidze[1], R. Vadatchkoria[1,2]

[1]Batumi Shota Rustaveli State University, Batumi, Georgia; [2]Avicenna – Batumi Medical University, Batumi, Georgia; [3]JSC Seamen's Medical Centre-2010, Batumi, Georgia; [4]"SoloMed" Clinic, Batumi, Georgia

Objectives. Osteoporosis is a chronic skeletal disease characterized by reducing of bone density, which leads to increased fragility and a higher risk of skeleton's bones fractures. As the global population ages, its prevalence and related healthcare costs are expected to rise, especially among postmenopausal women.**Aim of study.**This study aimed to assess bone density in menopausal women, given its critical importance to their health. Specifically, we sought to investigate the association between menopause and bone density, analyze regional variations, and systematically compare our findings with global data.Through this approach, we aimed to deepen understanding and contribute to improved clinical care for menopausal women in the Adjara Region. **Materials and Methods.** This study was conducted at JSC Seamen's Medical Centre-2010 in Batumi, Adjara, Georgia between 2023 and 2024.A total of 151 women aged 45-55 years were stratified into two age groups based on year of birth:1968-1974 and 1975-1979. Their bones condition were evaluated using an Ultrasound Bone Densitometer (Sonost 2000).Bone mineral density (BMD) was assessed according to World Health Organization criteria based on T-scores, expressed as standard deviations (SD).**Results.**The first group made up 70.2% of the participants (n=106),whereas the second group accounted for 29.8% (n=45).In the first group (1968-1974), 13.2% (n=14) were diagnosed with osteoporosis, 63.2% (n=67) with osteopenia and 23.6% (n=25) had normal bone density. Among the second group (1975-1979), 13.3% (n=6) were diagnosed with osteoporosis,57.8% (n=26) with osteopenia, and 28.9% (n=13) had normal bone density.**Conclusion.** Among the 151 participants, born between 1968-1979, 13.24% (n=20) were found to have osteoporosis, 61.58% (n=93) had osteopenia, and only 25.16% (n=38) exhibited normal bone density. Analysis of trend across various age groups reveals a concerning pattern: individuals in the first group are significantly more likely to experience osteopenia and osteoporosis. In contrast, individuals in the second group demonstrate a remarkable ability to maintain normal bone density. The findings indicate that approximately half of menopausal women in Adjara had osteopenia, one quarter had normal bone mineral density, and one in eight had osteoporosis. In contrast to global data, where osteoporosis affects approximately one third of menopausal women, the prevalence in our cohort was notably lower.**Keywords.** Menopause, Osteoporosis, T-score.

P272

TRYPTOPHAN–KYNURENINE PATHWAY ALTERATIONS IN THE SERUM OF OLDER ADULTS WITH DYNAPENIA AND SARCOPENIA

A. Wojszel[1], J. Śliwowski[2], J. Rentflejsz[1], E. Gorodkiewicz[3], J. Godzień[4], M. Ciborowski[4], Z. B. Wojszel[5]

[1]Medical University of Bialystok, Doctoral School, Białystok, Poland; [2]Medical Univeristy of Białystok, Department of Geriatrics, Interdisciplinary Students' Scientific Group, Białystok, Poland; [3]University of Białystok, Faculty of Chemistry, Bioanalysis Laboratory, Białystok, Poland; [4]Medical University of Bialystok, Clinical Research Centre, Metabolomics and Proteomics Laboratory, Białystok, Poland; [5]Medical University of Białystok, Department of Geriatrics, Białystok, Poland

Objectives: Age-related activation of the kynurenine pathway may contribute to sarcopenia by promoting oxidative stress and mitochondrial dysfunction in skeletal muscle. Given limited evidence in older adults, this study aimed to evaluate serum tryptophan (TRP) and its metabolites—kynurenine (KYN), 3-hydroxykynurenine (3-HK), and 3-hydroxyanthranilic acid (3-HAA)—in older adults with preserved muscle mass and strength (group A), dynapenia alone (group B), and sarcopenia (group C).
Materials and Methods: Patients aged ≥60 years hospitalized in a geriatric ward were included in the study. Dynapenia was defined as low handgrip strength (<16 kg in women, <27 kg in men). Sarcopenia was diagnosed based on dynapenia with low appendicular skeletal muscle mass (ASM; <20 kg in men, <15 kg in women), assessed by bioimpedance using the Sergi's equation. Serum TRP, KYN, and 3-HK were measured using RP-HPLC-UV, and 3-HAA using RP-HPLC. Analyses included Spearman correlation, Kruskal–Wallis test, and logistic regression.
Results: The study included 133 participants (mean age 79.0 ± 7.3 years; 72.9% women): 61.9% in group A, 6.3% in group B, and 31.7% in group C. Median serum TRP and KYN concentrations increased stepwise from group A to C (TRP p=0.09; KYN p=0.07), with similar non-significant trends for 3-HK and 3-HAA (p>0.1). ASM and ASM/height² were significantly inversely correlated with serum KYN and 3-HK. Logistic regression showed a higher likelihood of sarcopenia with older age (OR=1.15; 95% CI 1.07–1.23; p<0.001) and higher serum KYN (OR=1.024; 95% CI 1.004–1.044; p=0.017), independent of TRP levels and sex.
Conclusions: In older adults, increased kynurenine pathway activation is associated with reduced muscle mass and a higher risk of sarcopenia. Kynurenine-related metabolites may represent potential biomarkers and therapeutic targets for age-related muscle loss.
Acknowledgments: The authors would like to thank dr. Łukasz Ołdak for conducting biochemical analyses.

PHOSPHOLIPASE C-Y1 REGULATES BMSC FATE BY PROMOTING OSTEOGENESIS AND INHIBITING ADIPOGENESIS THROUGH THE CACNA1C/CA2+ PATHWAY

A. Xiong[1], Y. Gu[1], F. Xu[1], X. Xia[1], D. Dai[1], R. Sun[1], Y. Ling[1], L. Qiu[1], Y. Ding[1], Y. Yu[1], X. Cai[1], R. Zhang[2], D. Bikle[3], Z. Xie[1]

[1]National Clinical Research Center for Endocrine and Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Diseases, and Department of Metabolism and Endocrinology, The Second Xiangya Hospital of Central South University, Changsha, China; [2]Department of Medical Laboratory, Hunan Normal University School of Medicine, Changsha, China; [3]Departments of Medicine and Dermatology, University of California San Francisco and San Francisco Veterans Affairs Medical Center, San Francisco, United States

Objectives: Imbalanced differentiation of bone marrow stromal cells (BMSCs), characterized by enhanced adipogenesis and suppressed osteogenesis, is a key pathological mechanism in osteoporosis. This study aimed to elucidate the role and underlying mechanism of phospholipase C-γ1 (PLC-γ1) in BMSCs differentiation to identify novel therapeutic targets for osteoporosis.

Methods: PLC-γ1 was silenced in BMSCs *in vitro* to assess its effects on differentiation. Osteogenic markers and calcium nodule formation were measured, while adipogenic differentiation was evaluated via marker expression and Oil Red O staining. BMSC-specific PLC-γ1 conditional knockout (cKO) mice (floxed PLC-γ1, PRX1-Cre^{+}) were generated with floxed PLC-γ1 mice serving as controls. Femoral bone mineral density (BMD) and microstructure were analyzed by μ-CT, and formation of bone marrow adipocytes, osteoblasts, osteoclasts, and chondrocytes was histologically examined. RNA sequencing (RNA-seq) of BMSCs identified CACNA1C as a key potential downstream candidate. The IP_3 receptor, acting downstream of PLC-γ1, was silenced to evaluate osteogenic markers and CACNA1C expression. Confocal microscopy was used to determine whether the CACNA1 agonist Bay K8644 could rescue Ca^{2+} influx in PLC-γ1 deficient BMSCs. Finally, the ability of Bay K8644 to reverse the osteogenic-adipogenic imbalance and bone defects caused by PLC-γ1 knockout was tested both *in vitro* and *in vivo*.

Results: Silencing PLC-γ1 in BMSCs reduced osteogenic markers such as ALP activity and calcium nodule formation, while increasing adipogenic markers such as lipid droplet formation. PLC-γ1 cKO mice exhibited lower bone mass, impaired bone microstructure, reduced bone formation, and increased bone marrow adiposity. RNA-seq pinpointed CACNA1C as a significantly downregulated gene following PLC-γ1 knockout. Silencing the IP_3 receptor in BMSCs abolished the pro-osteogenic effect of PLC-γ1 and downregulated CACNA1C. Bay K8644 restored Ca^{2+} influx in PLC-γ1-deficienct BMSCs. Furthermore, Bay K8644 treatment rescued the impaired osteogenesis and enhanced adipogenesis *in vitro*, and ameliorated bone loss, microstructure deterioration, and marrow adiposity in PLC-γ1 cKO mice.

Conclusions: PLC-γ1 in BMSCs promotes osteogenic differentiation, inhibits adipogenic differentiation, and maintains normal bone mass via the CACNA1C-dependent calcium signaling pathway.

P274

ANALYSIS OF 25(OH)D LEVELS IN PATIENTS WITH OBESITY AND OSTEOPOROSIS

A. Zayaeva[1], Y. Shulezhko[1], G. Koshukova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Introduction. Vitamin D deficiency is one of the most important links in the pathogenesis of osteoporosis. Obesity plays a significant role among the factors affecting the synthesis and metabolism of vitamin D. Research objectives. To study the level of 25(OH)D in patients with obesity and osteoporosis.

Materials and methods. The level of vitamin D (intermediate form - 25(OH)D) in blood serum was analyzed in 82 patients with obesity and osteoporosis (27 men, 55 women aged 48–79 years). All patients calculated BMI according to A. Quetelet: body weight/height2 (kg/m2). With BMI ≥30 kg/m2 was diagnosed obesity. The diagnosis of diabetes mellitus was considered an exclusion criterion to avoid additional factors affecting the level of 25(OH)D.

Results and discussion. According to BMI indicators, patients were divided into 4 groups: 25 – 29.9 kg/m2 – overweight (n=19), 30 – 34.9 kg/m2 – obesity 1 degree (n=22), 35 – 39.9 kg/m2 – obesity 2 degree (n=27), 40 kg/m2 and more – obesity 3 degree (n=14). Most patients in groups 1 and 2 (73.7% and 72.7%) had vitamin D deficiency (25.8±2.6 ng/ml and 23.1±2.8 ng/ml), and no significant differences were found between the groups. Among patients in groups 3 and 4, vitamin D deficiency prevailed (16.7±4.1 ng/ml and 14.9±3.8 ng/ml), and there was a significantly higher number of patients ($p<0.05$) with severe vitamin D deficiency. A negative correlation was found between the level of 25(OH) D and BMI of patients ($r= - 0.12$, $p=0.04$), which allows us to consider obese patients as a risk group for vitamin D deficiency. No relationship was found with the age of patients.

Conclusions: patients with overweight have a decrease in vitamin D3 levels, and the degree of decrease correlates with the degree of obesity, which, in turn, increases the risk of osteoporosis. These findings justify the need to increase individual preventive doses of vitamin D3 in patients with obesity. Consequently, it is necessary to identify obese patients as a separate risk group for vitamin D deficiency, determine their serum 25(OH)D levels, and recommend higher doses of cholecalciferol if deficiency or insufficiency is detected.

CORTICAL AND TRABECULAR BONE CHANGES IN MEN WITH HAEMOPHILIA: FINDINGS FROM THE HAEMOPHILIA OSTEOPOROSIS REGISTRY (THOR)

A. Zengin[1], V. Gan[1], H. Tran[2], P. R. Ebeling[1]

[1]Department of Medicine, School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia; [2]Alfred Hospital, Haemophilia Treatment Centre, Melbourne, Australia

Objective: To compare cortical and trabecular bone density and microarchitecture at the radius and tibia in men with haemophilia (PWH) versus controls, and to examine change over one year.

Material and Methods: Eighty-seven men (76 controls, 11 PWH; ≥18 years) underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) at baseline and one-year follow-up at the 4% and

30% radius and tibia. Outcomes included total volumetric bone mineral density (vBMD), cortical vBMD, trabecular vBMD, trabecular number, and cortical thickness. Mixed-effects models tested group differences and longitudinal change using a time×group interaction term, reporting β-coefficients. Models were adjusted for age, weight, and height.
Results: After adjustment, PWH demonstrated substantially lower bone density and impaired microarchitecture compared with controls at both skeletal sites. At the radius, PWH had lower total vBMD (β=−57.3 mg/cm³, p<0.001), trabecular vBMD (β=−47.8 mg/cm³, p<0.001), trabecular number (β=−0.24 mm⁻¹, p<0.001), and cortical thickness (β=−0.30 mm, p=0.026). At the tibia, similar or greater deficits were observed, including reduced total vBMD (β=−54.8 mg/cm³, p<0.001), trabecular vBMD (β=−62.5 mg/cm³, p<0.001), trabecular number (β=−0.40 mm⁻¹, p<0.001), and cortical thickness (β=−1.50 mm, p<0.001). No significant change over time was detected in either group; all time×group interaction terms were non-significant (p>0.57), indicating comparable longitudinal trajectories over one year.
Conclusion: Men with haemophilia exhibit marked deficits in bone density and microarchitectural integrity at both the radius and tibia compared with controls, with stability of parameters over one year. These findings support routine bone health screening and targeted skeletal risk-reduction strategies in PWH.

P276
MUSCLE STRENGTH AND ITS CORRELATION WITH SERUM URIC ACID

A. Zoto[1], V. Salko[1], E. Rapushi[1]

[1]UHC"Mother Theresa", Tirana, Albania

Objective:
The study aimed to associate muscle strength with serum uric acid(UA) in adults with or without gout.
Material and Method:
This study included 100 male individuals, of whom 50 were known to have gout and the other 50 were not diagnosed with gout(they might have asymptomatic hyperuricemia or a normal level of uric acid). The mean age of the individuals was 55(SD 5.3) years, ranging from 43 to 74. The average time of established diagnosis(for gout patients) was 6 years. Most patients(35 patients) were taking long-term prevention with allopurinol or febuxostat. Muscle strength was measured using a handgrip dynamometer. The combined grip strength (sum of the highest values of both hands) was evaluated. Serum uric acid was measured twice at a six-month interval.
Results:
Evaluating the individuals without gout, UA was positively associated with muscle strength, especially in patients with asymptomatic hyperuricemia. In gout patients mean serum uric acid level was 6.9 mg/dl, but in this group, no positive correlation with muscle strength was observed.
Conclusion:
Serum UA is positively associated with handgrip strength in adults without gout. The presence of gout disease neutralizes the positive impact of high uric acid levels on muscle strength.

P277
OSTEOPOROSIS IN ANKYLOSING SPONDYLITIS

A. Zoto[1], V. Salko[1], V. Duraj[1], D. Ruci[1], T. Backa[2], E. Rapushi[1], A. Kollcaku[2], F. Spaho[2]

[1]University Hospital Centre “Mother Teresa”, Tirana, Albania;
[2]University Hospital Center "Mother Teresa", Tirana, Albania

Objective: Prevalence of osteoporosis and related factors in patients with ankylosing spondylitis

Material and Methods: This is a retrospective cohort study and includes 95 patients with ankylosing spondylitis who met the ACR/EULAR diagnostic criteria. Demographic data such as age and gender, disease duration, disease activity and medication use were analyzed. Disease activity was measured using the Ankylosing Spondylitis Disease Activity Score with C-reactive protein. Bone mineral density was measured by dual-energy X-ray absorptiometry and results were expressed as T-score (osteoporosis T-score ≤ −2.5).

Results: The average age of the patients was 46 years and the average duration of the disease was 8 years. 83% patients were male and 17% female. 64% patients had high disease activity and 36% had moderate disease activity. All patients were treated with biological disease-modifying anti-rheumatic drugs and non-steroidal anti-inflammatory drugs. Osteoporosis was found in 21% of patients with ankylosing spondylitis. In patients with high disease activity osteoporosis was found in 18%. In females, osteoporosis was found in 14%, while in males in 7%. In patients who had more than 5 years of ankylosing spondylitis, osteoporosis was found in 16%. Osteoporotic fractures were recorded in 2% of patients, mainly affecting the vertebrae and coxofemoral joints.

Conclusions: This study highlights the importance of assessing and monitoring bone density in patients with ankylosing spondylitis. High disease activity and its duration are risk factors for the development of osteoporosis. Females with ankylosing spondylitis are affected by osteoporosis more than males. Early identification and monitoring of bone density in these patients may allow for preventive interventions through medications and reduce osteoporosis complications, such as fractures.

P278
OSTEOARTHRITIS AND HYPOTHYROIDISM

A. Zoto[1], V. Salko[1], D. Ruci[1], V. Duraj[1], E. Rapushi[1]

[1]University Hospital Centre “Mother Teresa”, Tirana, Albania

Objectives: To determine the frequency of osteoarthritis in patients with hypothyroidism

Material and Methods: This is an observational study involving 80 patients with hypothyroidism who complained of joint and spine pain. All patients had been diagnosed with hypothyroidism and were being treated. Age and gender, disease duration, thyroid stimulating hormone, free thyroxin t4 and radiographs of the painful joints and spine were included and analyzed. X-ray criteria for osteoarthritis include joint space narrowing, osteophytes and subchondral sclerosis.

Results: The mean age of the patients was 42 years and the mean duration of the disease was 11 years. 64% of patients were female and 36% were male. Osteoarthritis was found in 15% of patients with hypothyroidism. 11% were female and 4% were male. Elevated thyroid stimulating hormone and free thyroxin t4 levels were found in 56%. Knee osteoarthritis was found in 7% of patients, hip osteoarthritis in 4%, spine osteoarthritis in 3% and hand osteoarthritis in 1%. In patients with the highest concentrations of thyroid stimulating hormone and free thyroxine t4, osteoarthritis was higher, in 12% of patients, compared with patients with normal levels of thyroid-stimulating hormone and free thyroxine t4, in 3% of patients.

Conclusions: Thyroid hormone metabolism plays an important role in osteoarthritis. Our study indicated that higher elevated thyroid stimulating hormone and free thyroxin t4 concentrations may increase the risk of osteoarthritis. Females with hypothyroidism are generally affected by osteoarthritis more than males

SURGICAL APPLICATION OF AN ADVANCED INTRAMEDULLARY TELESCOPIC CONSTRUCT FOR PATHOLOGICAL FEMORAL FRACTURES AND THEIR SEQUELAE IN PATIENTS WITH SYSTEMIC SKELETAL DISEASES

A. Zyma[1], I. Hertsen[2], T. Kinchaya-Polishchuk[2], A. Cheverda[2], O. Skuratov[2], A. Smaha[3]

[1]Institute of Orthopedics and Traumatology, National Academy of Medical Sciences, Kyiv, Ukraine, Kyiv, Ukraine; [2]Institute of Orthopedics and Traumatology, National Academy of Medical Sciences, Kyiv, Ukraine; [3]Chernivtsi city children`s clinical hospital, Chernivtsi, Ukraine

Objectives: To assess an advanced locked intramedullary telescopic construct for surgical management of pathological femoral fractures and deformities in patients with systemic skeletal diseases.
Material and Methods: A retrospective review included 17 ambulatory patients (10 females, 7 males; mean age 14.8 years, 8–21) with femoral pathological fractures/deformities due to osteogenesis imperfecta type I (9 patients), monostotic fibrous dysplasia (6 patients) or D-resistant rickets (2 patients). 17 procedures were performed: open reduction and osteosynthesis and, when indicated, corrective osteotomy (Sofield–Miller). Fixation used a locking rod (proximal locking holes; distal dual-plane locking) coupled with a T-shaped telescopic component with matching hole diameter and spacing. Distal locking was performed for both the rod and the telescopic component; after union, the inferior distal locking screw was removed to enable telescopic sliding. Follow-up was 5 years.
Results: Deformity correction and fracture/osteotomy union occurred within the expected timeframe in all cases. The construct provided stable fixation, prevented rotational and distraction displacement, and eliminated the need for cast immobilisation. No refractures or deformity recurrences were observed. Telescopic function and longitudinal bone growth were maintained, with improved lower-limb weight-bearing capacity.
Conclusions: This construct integrates stable locked intramedullary osteosynthesis with a growing telescopic rod, providing reliable fixation and sustained support for femoral growth in systemic skeletal diseases.

RESPIRATORY MUSCLE PERFORMANCE ASSESSED FOLLOWING INTERMITTENT HYPOXIA–HYPEROXIA THERAPY IN PATIENTS WITH METABOLIC SYNDROME AND MUSCULOSKELETAL COMORBIDITIES

A.-B. Uzun[1], A.-D. Nedelcu[1], D.-M. Iliescu[2], D.-E. Tofolelan[3], D. Oprea[4], L.-E. Stanciu[4], M.-G. Iliescu[4]

[1]Doctoral School, Faculty of Medicine, „Ovidius" University of Constanta, Constanta, Romania; [2]„Ovidius" University of Constanta, Constanta, Romania; [3]Department of Pulmonology, Faculty of Medicine, „Ovidius" University of Constanta, Constanta, Romania; [4]Department of Physical Medicine and Rehabilitation, Faculty of Medicine, „Ovidius" University of Constanta, Constanta, Romania

Objective: Musculoskeletal disorders and metabolic syndrome (MS) often coexist, and their combined presence may negatively affect respiratory function, highlighting the importance of interventions that address these conditions. Intermittent hypoxia-hyperoxia therapy (IHHT) consists of alternating cycles of low and high oxygen exposure and has been shown to produce notable effects on a variety of pathological conditions. The objective of this study was to investigate whether IHHT influences respiratory parameters measured using a device designed to evaluate the strength and performance of the respiratory musculature.
Material and methods: The study included 79 patients diagnosed with MS, all of whom also presented musculoskeletal disorders, admitted to the Balneal and Rehabilitation Sanatorium of Techirghiol, and underwent standard comprehensive medical rehabilitation. Respiratory muscle function was assessed in all patients using a portable device designed to evaluate inspiratory muscle performance.
Results: Maximum MIP ($p = 0.485$ vs. 0.390), mean MIP ($p = 0.464$ vs. 0.519), maximum PIF ($p = 0.856$ vs. 0.851), mean PIF ($p = 0.464$ vs. 0.519), maximum S-index ($p = 0.967$ vs. 0.510), and mean S-index ($p = 0.999$ vs. 0.568) showed no statistically significant differences between the intervention and control groups.
Conclusions: Since this device primarily targets the inspiratory muscles, the relatively short duration may be insufficient to induce significant adaptations in the musculature, even though IHHT is recognized for its potential to improve muscle endurance and pulmonary function.

SPECIFIC EVALUATION USING BIOELECTRICAL IMPEDANCE ANALYSIS IN ELDERLY PATIENTS WITH SARCOPENIA

A.-D. Nedelcu[1], A.-B. Uzun[1], L.-E. Stanciu[2], D. Oprea[2], M.-G. Iliescu[2]

[1]Doctoral School, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania; [2]Department of Physical Medicine and Rehabilitation, Faculty of Medicine, "Ovidius" University of Constanta, Constanta, Romania

Objective: The etiology of sarcopenia involves multiple risk factors, which are still not fully understood. Identifying the underlying mechanisms and developing targeted interventions are key focuses of current medical research (1). The objective of this study was to investigate whether tendencies toward dehydration are associated with an increased risk of sarcopenia in elderly patients undergoing rehabilitation.
Material and Methods: Forty medically stable elderly patients (≥65 years) admitted to the Balneal and Rehabilitation Sanatorium of Techirghiol were included. Sarcopenia was screened using the SARC-F questionnaire. Hydration status, total body water, intracellular water, extracellular water, skeletal muscle mass, and appendicular skeletal muscle mass were assessed using bioelectrical impedance analysis (BIA). Correlations between hydration status, muscle mass, and sarcopenia screening results were analyzed.
Results: A significant proportion of patients admitted to the rehabilitation unit screened positive for sarcopenia using the SARC-F questionnaire. Among these patients, hydration status showed a significant correlation with muscle parameters evaluated by BIA, suggesting that decreased hydration may contribute to reduced muscle quantity and quality.
Conclusion: These findings emphasize the importance of monitoring hydration, a potentially modifiable determinant, and underscore the need for further research to clarify the interplay between hydration, muscle composition, sarcopenia, and functional outcomes in rehabilitation.

POST-FRAGILITY FRACTURE OSTEOPOROSIS ASSESSMENT AND TREATMENT GAP IN A TERTIARY MILITARY HOSPITAL IN ROMANIA

A.-E. Ranetti[1], C. Spiroiu[1], F. M. Smeureanu[1], D. Chirita[1]

[1]Endocrinology Department, Central Military Hospital, Bucharest, Romania, Bucharest, Romania

Objective(s):

To evaluate endocrine-led osteoporosis assessment and initiation of anti-osteoporotic treatment following fragility fractures in a tertiary military hospital.
Material and methods:

We performed a retrospective audit of patients aged ≥50 years with low-trauma fractures who were evaluated by the Endocrinology Department during 2025. Collected data included age, sex, fracture site, documentation of osteoporosis risk assessment, laboratory evaluation for secondary osteoporosis (serum calcium, 25-hydroxyvitamin D, parathyroid hormone), prescription of calcium and vitamin D supplementation, initiation of anti-osteoporotic medication, and referral for specialist follow-up.
Results:

A substantial number of patients with fragility fractures were assessed, the majority being women. Hip and vertebral fractures were the most frequent fracture sites, followed by distal radius and proximal humerus fractures. Most patients underwent some degree of metabolic bone evaluation; however, laboratory assessment for secondary causes of osteoporosis was inconsistent. Calcium and vitamin D supplementation was commonly prescribed, while initiation of specific anti-osteoporotic therapy occurred in only a proportion of cases. A standardized post-fracture osteoporosis management pathway was not consistently available.
Conclusion(s):

Despite endocrinology involvement, significant gaps persist in post-fragility fracture osteoporosis assessment and treatment initiation. Implementation of a structured fracture liaison service–type pathway coordinated by endocrinology may improve secondary fracture prevention in this tertiary care setting.

BONE HEALTH OUTCOME FOLLOWING ADRENALECTOMY VERSUS CONSERVATIVE MANAGEMENT IN 119 POSTMENOPAUSAL WOMEN WITH NON-FUNCTIONAL ADRENAL TUMORS

A.-I. Trandafir[1]

[1]PhD Doctoral School of “Carol Davila” University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, “C.I. Parhon” National Institute of Endocrinology, 011863, Bucuresti, Romania

Background: Non-functional adrenal tumors (NFATs) might require adrenalectomy or a conservative strategy, both having a potential bone influence [1-10].
Objective: To compare the bone profile of postmenopausal women with NFATs who underwent either adrenalectomy or conservative management.
Methods: This is a retrospective, longitudinal, single-center study. Inclusion criteria: women in menopause (age range: 45 to 85 years) with NFATs. Exclusion criteria: prior exposure to anti-osteoporotic therapy, overt Cushing syndrome, hormonally active tumors, bone ailments. DXA parameters, bone turnover markers (BTMs) were assessed at baseline and during follow-up. This is a university hospital (tertiary center of endocrinology) analysis amid a real-life setting with ethical approval from both hospital and university (7634 from 04/04/2025 and 37 from 22/09/2025).
Results: 119 postmenopausal women were included, 89.1% were managed conservatively and 10.9% underwent adrenalectomy (age

groups at baseline: 60.9±7.2 versus 54.2±6.9 years, p=0.074). Mean follow-up duration was 28.5 ± 19.1 months. Postoperative insufficiency occurred in 7.7% (surgery group). L1-L4 lumbar and femoral neck BMD changes showed no-between group differences. Total hip T-score change in non-surgery group (-1.05 ± 1.04 to -1.04 ± 0.92) was statistically significant lower than found in surgery group (-1.75 ± 0.29 to -1.60 ± 0.56, p=0.023). BTMs' changes between the study groups were similar at the end of follow-up period: CrossLaps (p=0.26), osteocalcin (p=0.55), and P1NP (p=0.39).

Conclusion: In postmenopausal women with NFATs, adrenalectomy was associated with an improvement of hip DXA results with similar BTM change.

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Vitamin D deficiency represents a key modulator of bone metabolism in the context of advanced malignancy and bilateral adrenal insufficiency [1-10].

Methods: Case report. Ethical approval no. 37/22.09.2025.

Results: We present the case of a 52-year-old male with metastatic clear cell renal cell carcinoma and a complex oncologic–endocrine history. The patient had a prior cutaneous sebaceous carcinoma and was subsequently diagnosed with a large left renal tumor (16 cm) with bilateral adrenal, pulmonary, and cutaneous metastases. He underwent cytoreductive left radical nephrectomy with bilateral adrenalectomy, followed by systemic oncologic therapy. Postoperatively, permanent adrenal insufficiency developed, with persistently elevated ACTH requiring lifelong hormone replacement and prednisone adjustment. Imaging studies demonstrated osteoarticular degenerative changes and small osteolytic lesions, consistent with increased skeletal risk in the oncologic and endocrine context. Bone metabolism evaluation initially showed vitamin D deficiency 21.6 ng/mL (normal>30), associated with high resorption marker CrossLaps 1.15 ng/mL (normal:0.161-0.737). Vitamin D supplementation was started, leading to normalization of serum vitamin D concentrations 40.9 ng/mL (normal>30), and a subsequent reduction of bone resorption markers (normal:0.161-0.737). First-line immunotherapy was initiated, with continued vitamin D supplementation.

Conclusion: Maintaining adequate vitamin D levels may contribute to more favorable bone turnover dynamics, supporting its role as a modifiable factor in skeletal health in cancer-related adrenal insufficiency.

Objective: MACS may have significant metabolic and skeletal implications [1-10]. We report a complex endocrine case illustrating these effects beyond bone density.
Methods: Case report. Ethical approval was obtained from both hospital and university (7634 from 04/04/2025 and 37 from 22/09/2025).
Results: We present the case of a 75-year-old woman (menopause at 42 years) admitted for endocrine evaluation, referred for recurrent episodes of palpitations and hypertensive crises (systolic blood pressure up to 240 mmHg). Her medical history was notable for arterial hypertension, obesity, impaired glucose metabolism. Laboratory evaluation revealed impaired glucose metabolism with HbA1c=6.23% (normal:4.8-5.9) and fasting glucose 123=mg/dL. Adrenal hormonal evaluation showed low-normal ACTH=8.25pg/mL(normal:7.2-63.3), morning plasma cortisol=17.01µg/dL(normal:4.82-19.5), and incomplete suppression after 1-mg overnight dexamethasone=3.73µg/dL(normal<1.8), consistent with MACS. Plasma metanephrines and normetanephrines were within normal ranges, excluding pheochromocytoma. Computed tomography identified bilateral adrenal nodules measuring up to 2.8cm on the left and 2cm on the right. Vitamin D levels were insufficient=29.38ng/mL(normal:30-100). Bone turnover markers were within normal ranges: osteocalcin=21.62ng/mL(normal:15-46), P1NP=40.1ng/mL(normal:20.25–76.31), and CrossLaps=0.48 ng/mL(normal:0.152-0.858), PTH=51.74pg/mL(normal:17.3-74.1). DXA showed osteopenia, with L1-L4 BMD=1.002g/cm²,T-score=-1.6, Z-score=-0.2, femoral neck BMD=0.706g/cm²,T-score=-2.3, Z-score=-0.8, total hip BMD=0.788g/cm²,T-score=-1.8, Z-score=-0.5). Trabecular bone score was 1.275, indicating impaired bone microarchitecture. Vertebral fractures were identified on imaging. Osteopenia associated with impaired bone microarchitecture and vertebral fractures required antiresorptive therapy and vitamin D supplementation.
Conclusion: This case suggests that DXA alone may underestimate skeletal fragility in MACS, highlighting the need for comprehensive fracture assessment.

BONE FRAGILITY IN MILD AUTONOMOUS CORTISOL SECRETION (MACS) WITH PRIMARY HYPERPARATHYROIDISM (PHPT): BEYOND BONE DENSITY

A.-I. Trandafir[1], E. Petrova[2], A.-M. Gheorghe[3], O.-C. Sima[3], M. Costachescu[4]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: MACS may affect bone, particularly when associated with PHPT leading to vertebral fractures that may not be reflected by reduced bone mineral density (BMD) on DXA [1-9]. We report such a case.
Methods: Case report. Ethical approval was obtained from both hospital and university (7634 from 04/04/2025 and 37 from 22/09/2025).
Results: We present the case of a 78-year-old woman referred for endocrine evaluation of persistent hypercalcemia. Her medical history was notable for left breast cancer treated by mastectomy and chemotherapy, a hepatic lesion under surveillance, chronic kidney disease, and cardiovascular comorbidities. Hormonal evaluation showed low-normal ACTH=6.11pg/mL(normal:7.2-63.3), elevated morning plasma cortisol=20.25 µg/dL(normal:4.82-19.5), and incomplete suppression after 1-mg overnight dexamethasone=3.78µg/dL(normal<1.8), consistent with MACS.CT identified a left adrenal incidentaloma (1.21cm). Parathyroid ultrasound and CT identified a right superior parathyroid lesion (0.6cm).Laboratory findings were consistent with PHPT: serum total calcium was 10.4mg/dL(normal:8.6-10.3), and PTH=119.5pg/mL (normal:17.3-74.1), serum phosphorus was 4.6 mg/dL(normal:2.7-4.5). Vitamin D status was adequate under supplementation, with 25-hydroxyvitamin D=36.6ng/mL(30-100). Renal function showed chronic impairment, with creatinine=1.61mg/dL(normal:0.3-1.2), estimated glomerular filtration rate was approximately 30mL/min/1.73m². Bone metabolism evaluation demonstrated active remodeling, with bone turnover markers in the upper-normal range: osteocalcin=42.75ng/mL(normal:15-46),P1NP=48.82ng/mL(normal:20.25-76.31), alkaline phosphatase=146U/L(normal:40-150), and CrossLaps=0.72ng/mL(normal:0.33-0.782). DXA showed osteopenia: L1-L4 BMD=1.052g/cm²,T-score=-1.2, Z-score=0.9, femoral neck BMD=0.797g/cm²,T-score=-1.5, Z-score=0.5), total hip BMD 0.841=g/cm²,T-score=-1.2, Z-score=0.6, and distal radius BMD=0.807g/cm²,T-score =-1.3, Z-score=-0.8). Reduced trabecular bone score (1.182) and vertebral fracture indicated skeletal fragility despite DXA scores remaining above the osteoporotic threshold. Parathyroidectomy and

anti-osteoporotic therapy were recommended.
Conclusion: This case showed that MACS and PHPT may cause bone fragility that is underestimated by DXA.

BONE PROFILE IN POSTMENOPAUSAL WOMEN WITH ADRENAL TUMORS ACCORDING TO CORTISOL SECRETION STATUS: A CROSS-SECTIONAL STUDY

A.-I. Trandafir[1]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania

Background: Adrenal incidentalomas challenge current concepts of bone health, as even mild cortisol excess may exert clinically relevant skeletal effects, particularly in postmenopausal women [1-3].
Objective: To compare the bone profile of postmenopausal women with adrenal tumors according to cortisol secretion status, mild autonomous cortisol secretion (MACS) and non-functioning adrenal tumors (NFAs) with that of controls without adrenal tumors.
Methods: This is a retrospective study including women in menopause (age range: 45 to 85 years). Exclusion criteria: hormonally active adrenal tumors, bone-affecting conditions, and prior exposure to anti-osteoporotic therapy. Based on post 1 mg dexamethasone suppression test cortisol levels, patients with adrenal tumors were classified as MACS (cortisol>1.8µg/dL) or NFAs (cortisol≤1.8µg/dL), while controls had no adrenal tumors. BTMs and DXA-derived skeletal parameters, including TBS, were assessed. This is a university hospital analysis with ethical approval from both hospital and university (7634 from 04/04/2025 and 37 from 22/09/2025).
Results: In the total study population (N=461), demographic characteristics were comparable across MACS (N=33), NFAs (N=80), and controls (N=348), with no significant differences in age (61.19±8.15 vs 61.29±8.40 vs 61.60±7.80 years, p=0.926).

Body mass index (BMI) differed significantly across groups (p=0.018), being highest in the MACS group (31.25±6.11kg/m²). BTMs including osteocalcin, P1NP, and CrossLaps, were similar across groups, with no statistically significant differences (all p>0.8). Fragility fracture prevalence was similar in MACS (12.1%), NFA (7.5%), and controls (8.4%) (p = 0.715). BMD, T-scores, and TBS were similar across groups (all p>0.3).

DXA category distribution differed significantly (p=0.031), with higher osteoporosis prevalence in MACS (33.3%) and NFA (30.7%) than in controls (18.3%).
Conclusion: In postmenopausal women with adrenal tumors, MACS was associated with a higher BMI and an increased prevalence of osteoporosis, despite similar BMD values, BTMs, TBS and fracture prevalence compared with NFAs and controls.

IS VITAMIN D DEFICIENCY DURING PREGNANCY ASSOCIATED WITH ISOLATED LOW FT4 LEVELS ?

A.-M. Borissova[1], B. Trifonova[2], L. Dakovska[1], E. Mihailova[1], M. Vukov[1]

[1]University Hospital Sofiamed, University of Sofia St Kliment Ohridski, Sofia, Bulgaria; [2]University Hospital Sofiamed, Sofia University St Kliment Ohridski, Sofia, Bulgaria

Introduction: The literature has sought to determine the causes of isolated low serum FT4 levels with normal TSH levels during pregnancy, and so far the results have been contradictory and unclear. Vitamin D acts through its receptor (VDR), present in various tissues, including the thyroid gland, where it can directly regulate thyroid hormone production. Thus, vitamin D may influence thyroid function at the cellular level. FT3/FT4 are considered indicators of the complex relationship between thyroid hormone resistance and vitamin D metabolism. **Material and methods:** 547 pregnant Bulgarian women were studied, mean age 30±5 years. FT4 (9.3-17.0 ng/L), TSH (0.27-4.2 mIU/L), 25(OH)D (30-100 ng/ml) were studied. We introduced four categories of 25(OH)D - Severe deficiency <10 ng/ml; Moderate deficiency 10-20 ng/ml; Insufficiency 20-30 ng/ml; Sufficiency >30 ng/ml. From the entire group of 547 pregnant women, those with a FT4 level below 9.3 ng/L were selected, which turned out to be 26.3% (144/547). From this group (n-144) were separated: *Group 1.* pregnant women with hyperthyroidism – TSH <0.01 mIU/L and under thyreostatic treatment (n-7); *Group 2.* pregnant women with clinical hypothyroidism - TSH >4.2 mIU/L without or with treatment (n-70); *Group 3.* pregnant women with isolated low FT4 below 9.3 ng/L, with normal TSH (0.27-4.2 mIU/L) and without treatment (thyreostatic or levothyroxine) – n-67. **Aim:** This group 3 is the subject of our study in order to search for a possible relationship between vitamin D deficiency and an isolated low level of FT4. **Results:** It turned out that vitamin D deficiency in pregnant women was present in group 1 - 57.1% (4/7), in group 2 - 78.9% (56/70), in group 3 - 79.1% (53/67). In group 3, only 20.9% (14/67) of pregnant women have sufficient vitamin D level, compared to 79.1% (53/67) with varying degrees of deficiency / insufficiency (p<0.001) - namely severe deficience in 3.8% (2/53), deficiency in 41.5% (22/53) and insufficiency in 54.7% (29/53), NS. The combination of vitamin D

deficiency/insufficiency and isolated low FT4 is present in 3.8% (2/53) of pregnant women in the first trimester, 49.1% (26/53) in the second trimester and 47.1% (25/53) in the third trimester. Therefore, in 96.2% (51/53) the combination of both disorders is present in the second and third trimesters of pregnancy. **Conclusion:** The direct and significant relationship between vitamin D deficiency and isolated low FT4 levels leads us to believe that vitamin D deficiency may be the cause or at least contribute to isolated low FT4 levels.

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania, Bucharest, Romania

Background. Irisin represents a novel biomarker in the musculoskeletal health assessment, being released from the muscle as response to physical activity. Apparently paradoxical, irisin seems higher in obese vs non-obese subjects, probably in relationship with a complex panel of interferences between exerkines and adipokines, but only a limited amount of clinical data are available so far.
Objective. We aimed to assess the circulating (blood) irisin (CBI) in obese vs non-obese adults, in addition to glucose and bone status assessments.
Methods. This is a prospective clinical study. Inclusion criteria: menopausal adults, age ≥ 50, signed informed consent. Exclusion criteria: prior diagnosis of osteoporosis, malignancies, insulin therapy, bone metabolic disorders, chronic kidney disease. Protocol of fasting assays: CBI (ELISA, MyBioSource, catalogue number MBS706887, intra-/inter-assay precision: <8%/<10%), 25-hydroxyvitamin D (25OHD), PTH (parathomone), bone turnover markers (BTMs): osteocalcin, P1NP, CrossLaps; glycaemia, insulin (+ HOMA-IR calculation). DXA (GE Lunar Prodigy) provided bone mineral density/T-score. Ethical Committees approvals: 32/30.9.24 and 97/20.11.24 (two centers).
Results. Two sub-groups were analyzed based on body mass index (BMI): obese (BMI≥30kg/sqm) vs non-obese (O vs nonO group, 41 patients per group, age of 63.1±7.99 vs 62.9±10.5, p=0.9). CBI was statistically significant higher in O vs nonO group [median(interquartile interval) of 96.1(64.4-128.0) vs 50.1(30.4-94.7) ng/mL, p=0.01). 25OHD was statistically significant lower in O vs nonO group (26.7±7.1 vs 32.4±8.1 ng/mL, p=0.0008) with similar PTH and BTMs (p>0.5 for each). Glucose status showed higher fasting glycaemia (107.3±11.8 vs 98.7±12.2, p=0.002), insulin [51.8(4.4-6.3) vs 10.27(7.8-14.0), p=0.0002], HOMA-IR [2.85(1.9-3.6) vs 1.2(1.0-1.5). p=0.0002], respectively, increased femoral neck and total hip T-score (mean of -1 vs -1.2 SD, p=0.03, respectively, -0.17 vs -0.84 SD, p=0.007) in O vs non-O group.
Conclusion. Irisin is higher in obese vs non-obese, age- and sex-matched menopausal females.
Acknowledgment. This research is part of the project IRI-OP-OB "Crossroad of metabolism and bone: the impact of irisin, bone turnover and inflammatory markers in patients with menopausal osteoporosis and obesity" (PN-IV-P8-8.3-ROMD-2023-0262)

Background. There are only a limited number of studies to address the myokine irisin assays in daily practice in relationship with vitamin D (VD) status. VD might influence the secretion of myo/adipokines, but no clear relationship with irisin has been established yet.
Objective. We aimed to evaluate irisin levels in VD deficient (VDD) versus VD sufficient (VDS) females.
Methods. These are preliminary results of a bi-centric, prospective, transversal study (Ethical approvals: 32 from 09/30/2024 and 97 from 11/20/2024) in menopausal women who signed the informed consent. We excluded males, premenopausal women, individuals <50 years, adults with prior diagnosis of osteoporosis, parathyroid tumors, cancers, bone and kidney metabolic ailments, current exposure to corticotherapy or insulin therapy. Irisin was assessed via enzyme-linked immunosorbent assay (ELISA) kit, (MyBioSource, USA, San Diego) in addition to bone metabolism assessments, and central DXA (Lunar Prodigy).
Results. 48 patients were included in group VDD vs 41 in VDS [25-hydroxyvitamin D (25OHD) ≥30 ng/mL], that were age-matched (62.29±10.19 vs 63.56±8.16, p=0.5), and years-since-menopause-matched (15.82±9.55 vs 16.11±9.00, p=0.8). Ionized and total serum calcium, respectively, phosphorus, and PTH were similar 3.95±0.31

vs 4.11±0.27 mg/dL, p=0.07; 9.29 ±1.00 vs 9.53±0.46 mg/dL, p=0.16; 3.53±0.53 vs 3.73±0.49 mg/dL, p=0.6; 42.45±15.13 vs 42.09±15.63 pg/mL, p=0.9). Circulating irisin [median(IQR)] was similar between the groups: 91.85 (44.76-121.76) vs 71.17 (38.76-97.43) ng/mL (p=0.5). Total alkaline phosphatase was not statistically significant different in VDD vs VDS: 71.70 (62.60-83.89) vs 74.00 (65.92-82.71) U/L (p=0.58), neither osteocalcin: 19.26 (17.62-22.85) vs 21.06 (18.08-23.67) ng/mL (p=0.5), nor CrossLaps: 0.39±0.19 vs 0.40±0.16 ng/mL (p=0.7). Lumbar, femoral neck and total hip bone DXA-based mineral bone density were similar in VDD vs VDS.

Conclusion. Circulating irisin is similar in menopausal adults with normal and non-normal 25OHD levels.

Acknowledgment. This research is part of the project IRI-OP-OB "Crossroad of metabolism and bone: the impact of irisin, bone turnover and inflammatory markers in patients with menopausal osteoporosis and obesity" (PN-IV-P8-8.3-ROMD-2023-0262)

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania, Bucharest, Romania; [4]Department of Internal Medicine I and Rheumatology, "Dr. Carol Davila" Central Military University Emergency Hospital, 010825 Bucharest, Romania 3. Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania, Bucharest, Romania; [5]Department of Internal Medicine and Gastroenterology, "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania, Bucharest, Romania

Objective. Type 1 Diabetes Mellitus (T1DM) is a well-established fracture risk. [1–10] We aim to present a case of life-threatening metabolic instability post-surgery for femoral neck fracture (FNN). **Methods.** Case report (Ethical approval 758/3.11.2025). **Results.** A 59-year-old female (menopause at 50) with a decade-history of T1DM developed acute respiratory failure and severe metabolic anomalies 24-h post-surgery for low-trauma FNN. Emergency computed tomography pulmonary angiography excluded a pulmonary embolism and showed a thyroid incidentaloma of 1.67 cm without vertebral fractures. Recurrent diabetic ketoacidosis (pH of 7.0, glycaemia of 260 mg/dL, glycated haemoglobin A1c of 6.8%) required an intensive care stabilization. Lab findings revealed significant inflammation [C-reactive protein 85.87 mg/L (Normal<5)], hypocalcaemia [total serum calcium 8.17 mg/dL (Normal:8.8–10.6)], hypomagnesaemia [magnesium 1.77 mg/dL (Normal:1.90–2.5)], and normal phosphorus of 2.7 mg/dL (Normal:2.5–4.5), hypoproteinaemia [total proteins 6.28 g/dL (Normal:6.6–8.3)], hypoalbuminemia [3.4 g/dL (Normal:3.5–5.2)], normal thyroid function [thyroid stimulating hormone of 1.71 µUI/mL (Normal:0.35–4.94)] with negative autoimmunity. DXA confirmed osteoporosis: lowest T-score at L2-L4 lumbar spine of -4.5 (at FN of -3.1). Bisphosphonate therapy (risendronate) was initiated plus calcium and vitamin D. **Conclusion.** Novel diagnosis of osteoporosis might be established amid severe complication (FNN) in an individual with otherwise high-fracture risk. Real-life setting also requires a multidisciplinary team for the peri-fracture surgery and recovery in addition to starting anti-osteoporotic medication. Uncontrolled hypocalcaemia and severe metabolic anomalies might limit/postpone the intravenous medication as first-line.

Background/Objective: Early postoperative hypocalcemia is a frequent post-thyroidectomy (Tx) complication [1-10]. We aim to present such case of a female who underwent Tx for compressive goiter with retrosternal extension.

Method: Case report. Ethical approval: 35/09.22.2025.

Results: A 59-year-old female presented with dysphagia, dysphonia and cough. Normal thyroid function [TSH 0.37 mIU/mL (normal: 0.35-

4.94), freeT4 17.18 pmol/L (normal: 9-19)] and negative autoimmunity associated high-normal total calcium 10 mg/dL (normal: 8.6-10), reduced 25-hydroxyvitaminD 25 ng/mL (normal>30), normal PTH 39 pg/mL (normal: 17.3-74.1). DXA was normal: L1-L4 BMD 1.023 g/cm^2, T-score -0.2; femoral neck BMD 0.929 g/cm^2, T-score +0.7; total hip BMD 1.115 g/cm^2, T-score +1.4. Cervical ultrasound revealed multinodular goiter with left lobe retrosternal extension. Computed tomography confirmed retrosternal extension in upper mediastinum, anterior and posterior of the left trachea, in contact with carotid arteries and jugular veins and mediastinal vessels. She underwent Tx with benign follicular disease confirmation. First day postoperatively, she developed symptomatic hypocalcemia (total calcium 8.31 mg/dL), which was managed with cholecalciferol 4000 UI/day and IV/oral calcium, followed by a normalization within 3 days (total calcium 9.6 mg/dL, 25-hydroxyvitamin D 29.55 ng/mL, and PTH 22.97 pg/mL). Two months post-surgery, mineral metabolism remained normal (total calcium 9.04 mg/dL, 25-hydroxyvitaminD 35.05 ng/mL) under cholecalciferol 2000 UI/day.
Conclusion: Hypocalcemia requires a multidisciplinary team upon Tx especially in large or retrosternal goiters.

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [5]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Long-term hypo-estrogenism in teenagers and young adults impairs peak bone mass and bone mineral density (BMD). We aim to introduce such a case [1-10].
Method: Case report. Ethical approval no. 35/22.09.2025.
Results: A 24-year-old female, with primary amenorrhea and hypergonadotropic hypogonadism, was admitted for bone status assessment for the first time across lifespan. Genetic testing: 46 XX karyotype; MLPA testing for CYP21A2 revealed no pathogenic variants. The patient refused estrogen replacement until the age of 22, when she started estradiol valerate 2 mg and norgestrel 0.5 mg. After 2 years, she ceased oral estrogens due to liver cytolysis. After 3 months: FSH 58.27 mUI/mL (normal:3.85-8.78), LH 61.55 mUI/mL (normal:2.12-10.89), estradiol 16.56 pg/mL (normal:22.4-115), testosterone 0.81 ng/mL (normal:0.1-0.75). Mineral metabolism was normal: total calcium 9.9 mg/dL (normal:8.5-10.2), 25-hydroxyvitamin D 39.39 ng/mL (normal>30), PTH 21.18 pg/mL (normal:17.3-74.1). Bone formation marker osteocalcin was normal 25.24 ng/mL (normal:15-46), with high resorption marker CrossLaps 0.86 ng/mL (normal:0.33-0.782). DXA showed low BMD for age (no incidental fractures): L1-L4 BMD 1.106 g/cm^2, Z-score -1.5, femoral neck BMD 0.834 g/cm^2, Z-score -2.0; total hip BMD 0.836 g/cm^2, Z-score -1.8, with partially degraded microarchitecture TBS 1.299. The patient restarted oral estrogen replacement with ethynyl estradiol 0.02 mg and drospirenone 3 mg, and continued cholecalciferol 2000 UI/day.
Conclusion: Estrogen replacement remains the first option for a low BMD in young adults, especially if there are no fractures.

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Defective osteomalacia-related bone mineralization impairs bone microarchitecture and strength causing bone deformities, and high fracture risk, which can be further enhanced by hyperparathyroidism [1-10]. We aim to introduce such case.
Method: Case report. Ethical approval 35/22.09.2025.
Results: A 52-year-old female underwent left parathyroidectomy for osteomalacia-related tertiary hyperparathyroidism (THP) due to uncontrolled osteomalacia 17 years ago (menopause at 47). Then, severe osteoporosis (vertebral, rib and clavicular fractures) required 5-year bisphosphonates regimen, followed by drug holiday. After 9 years, DXA-BMD showed osteopenia: lumbar BMD 1.116 g/cm^2, T-score -0.5; total hip BMD 0.984 g/cm^2, T-score -0.1; third distal radius BMD 0.666 g/cm^2, T-score -2.4. Zoledronate 5 mg/year was administered. One year later, normal total calcium 9 mg/dL (normal:8.5-10.2), normal PTH 74.1 pg/mL (normal:17.3-74.1), low 25-hydroxyvitamin D 19.7 ng/mL (normal>30), supressed bone turnover markers: osteocalcin 12.82 ng/mL (normal:15-46), P1NP 16.08 ng/mL (normal:20.25-76.31), and CrossLaps 0.13 ng/mL (normal:0.33-0.782) were found. DXA was stationary: lowest T-score at third distal radius BMD 0.658 g/cm^2, T-score -2.5. No parathyroid remnant tumours were found at 99m-Technetium sestamibi scintigraphy. Computed tomography revealed post-osteomalacia hourglass shaped thorax. Incidental fractures (T7, T8 and T9) required continuing bisphosphonates.
Conclusion: Uncontrolled hypovitaminosis D causing THPT may lead to multiple fractures even in young adults, requiring parathyroidectomy in severe cases. Overlapping menopausal osteoporosis poses supplementary therapy challenges.

Background/Objective: Non-functioning parathyroid adenomas are rare tumours incidentally discovered during imaging for unrelated ailments [1-10]. We aim to introduce such case.
Method: Case report. Ethical approval no. 35 from 09/22/2025.
Results: A 62-year-old female was admitted for paraesthesia and muscle cramps. (menopause at 54). She had normal serum total calcium 9.9 mg/dL (normal: 8.5-10.2), ionized calcium 3.9 mg/dL (normal: 3.9-4.9), PTH 40 pg/mL (normal: 17.3-74.1), and 25-hydroxyvitaminD 62 ng/mL (normal>30), reduced bone formation marker osteocalcin 12 ng/mL (normal: 15-46), but normal P1NP 20 ng/mL (normal: 20.25-76.31), and normal resorption marker [CrossLaps 0.18 ng/mL (normal: 0.177-1.015)]. DXA confirmed osteoporosis: L1-L4 lumbar BMD 0.864 g/cm^2, T-score -1.7; femoral neck BMD 0.569 g/cm^2, T-score -2.5; total hip BMD 0.664 g/cm^2, T-score -2.3; third distal radius BMD 0.654 g/cm^2, T-score -0.7. The patient received IV zoledronate 5 mg/year. Starting from a neck ultrasound, computed tomography confirmed a right parathyroid adenoma of 0.68x1.08x1.01 cm (without primary hyperparathyroidism). During 1-year follow-up, calcium and PTH remained normal: total calcium 9.4 mg/dL, PTH 69.58 pg/mL, 25-hydroxyvitamin D 40.54 ng/mL. Bone turnover markers remained stationary, except for low resorption (CrossLaps 0.05 ng/mL). Cervical ultrasound revealed a stationary parathyroid tumour of 0.46x0.62x0.26 cm. Parathyroid 99m-Technetium

sestamibi scintigraphy did not show any hyperactive foci.
Conclusion: Whether intermittent PTH secretion from non-functioning adenomas contributes to osteoporosis remains an open issue. A potential switch from a non-functional profile to primary hyperparathyroidism requires lifelong follow-up.

Background/Objective: Normocalcemic primary hyperparathyroidism may present classical complications (e.g. osteoporosis) or asymptomatic with accidental detection [1-10]. We aim to introduce such case.
Method: Case report. Ethical approval 35/22.09.2025.
Results: A 54-year-old female (menopause at 48), with Graves' disease treated with radioiodine iodine therapy 7 year prior, showed during surveillance intermittently high serum total calcium (ranges:10.2–10.7 mg/dL, normal:8.4–10.2) and PTH (ranges:65–82.28 pg/mL, normal:15-65), with normal bone formation markers osteocalcin 44.94 ng/mL (normal:15–46), P1NP 76.29 ng/mL (normal:20.25–76.31). and increased resorption CrossLaps 0.91 ng/mL (normal:0.33–0.782), DXA revealed osteopenia: L1–L4 BMD 1.050 g/cm^2, T-score -1.1, Z-score -1; femoral neck BMD 0.840 g/cm^2, T-score -1.2, Z-score -0.9; total hip BMD 0.880 g/cm^2, T-score -1.0, Z-score -0.9. After 7 years, serum total calcium was mildly increased 10.3 mg/dL with normal ionized calcium 4.08 mg/dL (normal:3.8-4.8), PTH 66.31 pg/mL, 25-hydroxyvitaminD 28.86 ng/mL (normal>20), and no kidney dysfunction/stones. DXA-BMD was stationary: L1–L4 BMD 1.101 g/cm^2, T-score -0.7; femoral neck BMD 0.830 g/cm^2, T-score -1.2; total hip BMD 0.855 g/cm^2, T-score -1.0; third distal radius BMD 0.844 g/cm^2, T-score -0.4. During follow-up, neck ultrasound and 99m-Technetium sestamibi scintigraphy were negative; currently, computed tomography detected a left para-tracheal parathyroid nodule of 1.19 cm. Further cholecalciferol was continued (1000 UI/day).
Conclusion: This case highlights the importance of longitudinal assays in normocalcemic hyperparathyroidism, due to their high variability, heterogeneous presentation, and localization challenges for small parathyroid tumours.

Background/Objective: Multiple endocrine neoplasia (MEN) type 4 is found in patients with negative MEN1 testing (acromegaly and primary hyperparathyroidism) [1-10]. We aim to introduce such case.
Method: Case presentation (ethical approval no. 35/22.09.2025)

Results: A 58-year-old female (menopause at 52) had hypophysectomy and gamma knife radiotherapy for somatropinoma causing acromegaly and continued with octreotide LAR and cabergoline. One decade later, normocalcemic hyperparathyroidism was confirmed based on total serum calcium 10.1 mg/dL (normal:8.6-10), PTH 118 pg/mL (normal:17.3-74.1) with normal 25-hydroxyvitamin D 29.86 ng/mL (normal>30), bone turnover markers: osteocalcin 28.65 ng/mL (normal:15-46), P1NP 62.64 ng/mL (normal:20.25-76.31), CrossLaps 0.57 ng/mL (normal:0.183-1.06). Osteopenia (lowest T-score at third distal radius: BMD 0.772 g/cm^2, T-score -1.2, Z-score -0.5) plus vertebral fractures at T10, T11, T12 required zoledronate 5 mg/year. Ultrasound, computed tomography, and 99m-Technetium sestamibi scintigraphy found a right lower parathyroid tumour of 2.3 cm. For 2 years, she developed kidney micro-stones and experienced normal/high-normal calcaemic level and stationary PTH until she agreed for parathyroidectomy. Menin testing was negative. One day postoperatively she had hypocalcaemia: total calcium 7.33 mg/dL with normal PTH 47.1 pg/mL, but 3 months later, high PTH relapsed (with normal total calcium, vitamin D and kidney function) in addition to negative imaging testing for a parathyroid tumour.
Conclusion: Negative MEN1 in acromegalic patient with a parathyroid tumour is suggestive for MEN4. Normocalcemic variant may be part of the phenotype, and does not exclude complications (e.g. fractures).

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [6]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova

Background/Objective: Glucocorticoid and thyroid replacement in autoimmune poly-glandular syndrome type 2 (APS2) might contribute to bone loss. Comorbidities such as secondary hyperparathyroidism due to chronic kidney disease (CKD) further increase fracture risk [1-10]. We aim to introduce such case.
Method: Case report (ethical approval 35/22.09.2025)

Results: A 55-year-old-female with APS2 syndrome (menopause at 45) developed primary adrenal insufficiency at 47 [morning plasma cortisol 6 mg/dL (normal:6.7-22.6)] and myxoedema [TSH 46 mUI/mL (normal:0.5-4.5), free thyroxine 8.47 pmol/L (normal:9-19)] requiring prednisone and levothyroxine replacement. DXA showed osteopenia:

L1–L4 BMD 0.906 g/cm^2, T-score -2.3; femoral neck BMD 0.726 g/cm^2, T-score -2.2; total hip BMD 0.887 g/cm^2, T-score -1. After 3 years, osteoporosis was confirmed: L1–L4 BMD 0.834 g/cm^2, T-score -2.9; femoral neck BMD 0.705 g/cm^2, T-score -2.4; total hip BMD 0.887 g/cm^2, T-score -1. She started denosumab (60 mg/6 months). After 1 year, secondary hyperparathyroidism was confirmed amid CKD: total serum calcium 8.57 mg/dL (normal:8.4-10.3), PTH 149.5 pg/mL (normal:15-65), 25-hydroxyvitamin D 27.1 ng/mL (normal>30); creatinine 1 mg/dL (normal:0.5-1.2); eGFR 67mL/min/1.73m^2 (Normal>90). She had normal osteocalcin 22.79 ng/mL (normal:15-46), and suppressed resorption marker CrossLaps 0.14 ng/mL (normal:0.33-0.782). DXA showed lowest T-score of -1.9 (L1–L4 BMD 0.955 g/cm^2) and an incidental T5 vertebral fracture. Denosumab was continued in association with alphacalcidol.
Conclusion: Glucocorticoid and thyroid replacement might interplay with osteoporosis management in APS2 across lifespan.

Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Fragility fractures in men are frequently associated with secondary causes such as hypogonadism, hypercortisolism or other endocrine anomalies [1-10]. We aim to introduce such case.
Method: Case report. Ethical approval: 35/22.09.2025.
Results: A 57-year-old male was admitted for neck compressive goitre with positive Pemberton sign. He had altered glucose tolerance (2-h glucose of 182 mg/dL during 75-gram oral glucose tolerance test) with normal thyroid function [TSH 1.32 mIU/mL (normal:0.35-4.94), freeT4 13.83 pmol/L (normal:9-19)] and negative thyroid antibodies. Thyroid ultrasound showed multinodular goitre with retrosternal extension that required computed tomography (which confirmed it and incidentally detected T8, T9, T10, L4, and L5 vertebral fractures). The patient had normal adrenal [ACTH 15.72 pg/mL (normal:7.2-63.3), morning cortisol 7.01 mg/dL (normal:4.82-19.5)] and gonadal function [FSH 7.52 mUI/mL (normal:1.27-19.26), testosterone 3.5 ng/mL (normal:1.75-7.81)]. Mineral metabolism was normal [total serum calcium 9.03 mg/dL (normal:3.9-4.9), PTH 35.58 pg/mL (normal:17.3-74.1), 25-hydroxyvitamin D 43.06 ng/mL (normal>)], so were bone turnover markers [alkaline phosphatase 77 U/L (normal:40-150), osteocalcin 22.36 ng/mL (normal:15-46), CrossLaps 0.52 ng/mL (normal:0.33-0.782)]. DXA showed low BMD for age: L1–L4 BMD 1.039 g/cm^2, T-score -1.6, Z-score -2.0; femoral neck BMD 0.799 g/cm^2, T-score -2.1, Z-score -1.7; total hip BMD 0.941 g/cm^2, T-score -1.1, Z-score -1. He underwent total thyroidectomy, and started zolendronate 5 mg/year.
Conclusion: Incidentally detected fractures may uncover osteoporosis in males without traditional risk factors.

Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Primary hyperparathyroidism (PHPT) increases risk of osteoporosis and cardiac arrhythmias [1-10]. We aim to introduce such patient.
Method: Case report (Ethical approval no. 35/22.09.2025)

Results: A 69-year-old female (menopause at 39) was admitted for symptomatic atrial fibrillation and hypercalcemia. Medical history includes: persistent PHPT for the past 12 years after right parathyroidectomy (PTx), complicated with osteoporosis (she underwent bisphosphonates for 3 years, followed by denosumab 7 months prior due to bone metastases from a breast carcinoma), kidney stones and atrial fibrillation. After PTx, she had persistently high PTH up to 93 pg/mL (normal:17.3-74.1) and total serum calcium 11 mg/dL (normal:8.4-10.2). DXA showed osteoporosis with lowest T-score -2.5 at femoral neck, and partially degraded microarchitecture (TBS 1.241). Ultrasound revealed a right parathyroid adenoma of 0.66 X 0.43 cm. On current admission, total calcium was high 10.3 mg/dL. She underwent re-do right PTx. One day postoperatively normal total serum calcium 9.6 mg/dL and PTH 69 pg/mL were found. One month postoperatively mineral metabolism was normal [total calcium 9.6 mg/dL, PTH=24.92 pg/mL, 25-hydroxyvitamin D 27.15 ng/mL (normal>30)]. Bone turnover markers were suppressed: osteocalcin 8.88 ng/mL (normal:15-46), P1NP 13.31 ng/mL (normal:20.25-76.31), CrossLaps 0.12 ng/mL (normal:0.33-0.782). DXA showed a BMD improvement: L1–L4 BMD 1.033 g/cm^2, T-score -1.2; femoral neck BMD 0.697 g/cm^2, T-score -2.4; total hip BMD 0.851 g/cm^2, T-score -1.2; third distal radius BMD 0.727 g/cm^2, T-score -1.7. She continued denosumab.
Conclusion: Overlapping PHPT-related osteoporosis and mammary cancer-associated bone metastases requires a tailored interventional strategy.

Background/Objective: Osteogenesis imperfecta (OI) leads to bone fragility from young ages [1-10]. We aim to introduce the OI-related bone status in a young female.
Method: Case report (Ethical approval 35/22.09.2025)

Results: A 30-year-old woman with OI was admitted for bone evaluation. Medical history included short stature and kidney stones. She had positive maternal history of OI, but her two siblings were OI-free. At the age of 18, DXA showed reduced BMD for age, with lowest Z-score -3.0 (lumbar L1-L4) and multiple fractures (including vertebral). IV ibandronate for 3 years was administrated, followed by zoledronate 5 mg/year, with an additional incidental vertebral fracture. After another 2 years, DXA showed: L2–L4 BMD 0.951 g/cm^2, Z-score -1.2; femoral neck BMD 0.836 g/cm^2, Z-score -0.9; total hip BMD 0.882 g/cm^2, Z-score -0.4, and drug holiday was initiated and prolonged for 7 years. Latest follow-up revealed normal mineral metabolism parameters: total serum calcium 9.6 mg/dL (normal:8.5-10.2), PTH 52.2 pg/mL (normal:17.3-74.1), 25-hydroxyvitamin D 20.3 ng/mL (normal>30), osteocalcin 21.01 ng/mL (normal:11-43), P1NP 37.61 ng/mL (normal:15.13-58.59), and CrossLaps 0.152 ng/mL (normal:0.136-0.689). DXA confirmed a stationary BMD: L2–L4 BMD 0.993 g/cm^2, T-score -1.7, Z-score -0.9; femoral neck BMD 0.867 g/cm^2, T-score -0.9, Z-score -0.3; total hip BMD 0.894 g/cm^2, T-score -0.9, Z-score -0.2/ No incidental fractures were found. The patient remained in drug holiday.
Conclusion: Bisphosphonates remain an important tool for improving fracture risk even in young patients with OI, but decision of drug holiday should be taken into consideration according to the real-life outcome.

Background/Objective: A frequent complication after total thyroidectomy (Tx) is hypocalcaemia, while dysphonia is rarely found nowadays [1-10]. We aim to introduce the case of a young female with post-Tx hypocalcaemia and dysphonia.
Method: Case report (Ethical approval 35/22.09.2025)

Results: A 32-year-old female was admitted post-Tx for Graves's disease with postpartum onset. Prior to Tx, the patient had normal serum total calcium [9.1 mg/dL (normal:8.4-10.2)] and 25-hydroxyvitamin D [30.7 ng/mL [normal>30)] under cholecalciferol 2000 UI/day. Thyroid function normalized [thyroid stimulating hormone (TSH) 3.5 mIU/mL (normal: 0.35-4.94)] under methimazole. Thyroid antibodies were positive [anti-thyroperoxidase 75.77 UI/mL (normal<16), anti-thyroglobulin 220.2 UI/mL (normal:0-115), anti-TSH receptor antibody 3.16 UI/L (Normal<1.75)]. Cervical ultrasound showed a large goitre before Tx. Post-Tx pathological report confirmed adenomatous nodular goitre and lymphocytic thyroiditis. Postoperatively she developed symptomatic hypocalcaemia for which she received alfacalcidol and calcium supplementation (IV and oral). The patient also experienced dysphonia (bilateral recurrent laryngeal nerve paresis) requiring oral methylprednisolone for one month. A week postoperatively serum calcium normalised 8.6 mg/dL, but PTH remained low 15.63 pg/mL, with further normalization within one month. Dysphonia improved within 5 months.
Conclusion: Hypocalcaemia does not necessarily correlates with dysphonia following Tx, but highlights a more difficult surgical approach (e.g. large goitre, fibrosis post-methimazole). Corticotherapy to address dysphonia might aggravate dysphonia.

Objective: Male osteoporosis is usually related to secondary causes such as hyperthyroidism and excessive cortisol secretion [1-10]. We aim to introduce such patient.
Method: case report. Ethical approval no. 29336 from 10/17/2025.
Results: A 59-year-old male had a history of toxic multinodular goiter for the past 2 years and a recent episode of acute bilateral submaxillary sialadenitis. On admission, he had normal thyroid stimulating hormone and free levothyroxine under thiamazole 5 mg/day and negative anti-thyroid antibodies. Computed tomography showed bilateral adrenal tumors of 1.8 cm on the right and 2.4 cm on the left. Basal adrenocorticotropic hormone was low-normal [8.98 pg/mL(normal:7.2-63.3)], high-normal plasma morning cortisol [16.47µg/dL(normal:4.82-19.5)] and cortisol after 1-mg-dexamethasone suppression test indicated mild

autonomous cortisol secretion(MACS) [1.88µg/dL(normal:<1.8)]. Mineral metabolism and bone turnover markers were normal. Dual-Energy X-Ray Absorptiometry(DXA) confirmed osteoporosis: lumbar BMD 0.838g/sqcm, T-score -3.2, femoral neck BMD 0.722g/sqcm, T-score -2.7, total hip BMD 0.809g/sqcm, T-score -2.2. Bone microarchitecture was partially degraded (TBS 1.322). He had vertebral fractures at spine X-Ray and bone scintigraphy showed degenerative changes in multiple joints. Zoledronate 5mg/year was administered in addition to cholecalciferol 2000IU/day and decision of total thyroidectomy was made. Genetic testing was recommended due to bilateral adrenal tumors but the patient declined.

Conclusion: Hyperthyroidism and MACS have a negative impact on bone health and decision of pharmacological or surgical intervention must be individualized.

Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [3]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Hypoparathyroidism is one of the most clinically important complications of thyroidectomy, either by incidental removal or temporary damage of the parathyroid glands [1-10]. We aim to introduce a patient with postoperatory hypoparathyroidism after thyroidectomy for differentiated thyroid carcinoma (TC).

Method: case report. Ethical approval no. 29336 from 10/17/2025.

Results: A 46-year-old male was admitted for evaluation after total thyroidectomy for papillary TC. He was known with macroprolactinoma diagnosed at 39 complicated with hypogonadotropic hypogonadism, central hypothyroidism and adrenal insufficiency. The patient followed cabergoline 0.5mg/week but self-decided to stop levothyroxine and prednisone substitution at 41. Currently, thyroid panel showed high Thyroid Stimulating Hormone(TSH) 5.6µIU/mL(normal:0.35-4.94) and normal free levothyroxine 11.52pmol/L(normal: 9-19) under levothyroxine 100µg/day with negative thyroglobulin. Mineral metabolism revealed low parathormone 14.68pg/mL(normal:17.3-74.1), normal blood calcium 9.73mg/dL(normal:8.6-10), high phosphorus 4.8mg/dL(normal:2.5-4.5) and normal 25-hydroxyvitamin D 32.92ng/mL(normal: >30) under vitamin D supplements. Prolactin was high 22.12ng/mL(normal:2.64-13.13) under cabergoline 1 mg/week; adrenocorticotropic hormone and morning plasma cortisol were normal. Oral calcium supplements, alphacalcidol 0.5µg/day were initiated and radioiodine (50mCi) administration was decided; cabergoline was increased to 1.25mg/week.

Conclusion: Biochemical and hormonal screening for hypoparathyroidism is mandatory after total thyroidectomy, especially when radioiodine and TSH suppressive therapy are necessary and pituitary disorder is present in order to prevent long-term impact on bone health.

Objective: Soft tissue sarcomas are highly aggressive tumors with rapid local invasion and potential involvement of adjacent skeletal structures [1-9]. We aim to introduce such case.
Method: case report. Ethical approval no. 29336 from 10/17/2025.
Results: This was a 57-year-old female admitted for a progressively growing mass on the anterior left for the past 5 months. She was known with total thyroidectomy for multinodular goiter 13 years prior. At clinical examination, the mass was painful but without local inflammatory signs. Magnetic resonance imaging(MRI) revealed a tumor of 4.8/2.5/4.6 cm in the adipose tissue of the proximal third on the left calf with aggressive features, dermal extension and no periosteal/cortical invasion. Computed tomography confirmed the soft tissue mass with heterogeneous aspect. Bone scintigraphy showed an area with mildly increased uptake in the proximal left tibia. Mineral metabolism assays showed normal blood calcium and phosphorus, high 25-hydroxyvitamin D 55ng/mL(normal:30-100) with low-normal parathormone 18.13pg/mL(normal:17.3-74.1). Osteocalcin was low 13.99ng/mL(normal:15-46), normal alkaline phosphatase 93IU/L(normal:35-104), P1NP 73.18ng/mL(20.25-76.31) and CrossLaps 0.32ng/mL(normal:0.183-1.06). Surgical excision of the tumor was performed and pathological report revealed high-grade undifferentiated pleomorphic sarcoma pT2NxG3 and Ki67 60% at immunohistochemistry. Next generation sequencing for genetic tumoral profile evaluation was declined by the patient. She was referred to oncologic monitoring and decision of adjuvant therapy.
Conclusion: Multidisciplinary approach and precise imaging assessment are mandatory to establish tumor origin and correct management of aggressive soft tissue sarcomas.

OSTEOPENIA IN A PATIENT WITH NEWLY DETECTED BREAST MALIGNANCY: CHALLENGES OF MANAGEMENT

M. Costachescu[1], O.-C. Sima[2], E. Petrova[3], A.-M. Gheorghe[2], A.-I. Trandafir[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital, Bucharest, Romania; [2]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [3]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Breast cancer and its management, including surgery, radiotherapy, chemotherapy and aromatase inhibitors have a negative impact on skeletal health and can accelerate bone loss [1-10]. We aim to introduce such case.
Method: case report. Ethical approval no. 29336 from 10/17/2025.
Results: A 50-year-old female with personal history of recurrent nephrolithiasis was admitted for calcium-phosphate metabolism assessment. Clinical evaluation revealed hypoplastic right breast compared to the left with skin retraction. Of note, her family medical history included her aunt and cousin with breast cancer. Biochemical panel showed mild anemia and leukopenia, normal renal function and electrolytes. Blood calcium was normal [9mg/dL (normal: 8.5-10.2)], as well as 25-hydroxyvitamin D [28.7ng/mL (normal: >30)] and parathormone [35.31pg/mL (normal: 17.3-74.1)]. Bone turnover markers were normal. Dual-Energy X-Ray Absorptiometry(DXA) revealed osteopenia: L1-L4 BMD 1.026g/sqcm, T-score -1.4, femoral neck BMD 0.778g/sqcm, T-score -1.7, total hip BMD 0.822g/sqcm, T-score -1.5 and partially degraded bone microarchitecture (TBS 1.320). Breast ultrasound showed a mass of 1.3 cm with spiculated margins and internal calcifications in the right breast. Computed tomography confirmed right breast calcification of 1.24 cm with an adjacent mass of <1 cm. Tumor markers such as carcinoembryonic antigen were negative. She was referred to oncologic and surgical evaluation for decision of conservative or operative treatment.
Conclusion: Careful monitoring of bone status is mandatory for patients with breast cancer especially when aromatase inhibitors are recommended in order to initiate adequate antiosteoporotic medication.

CLINICAL CONSEQUENCES OF HYPOPARATHYROIDISM AFTER TOTAL THYROIDECTOMY FOR DIFFERENTIATED THYROID CANCER

M. Costachescu[1], O.-C. Sima[2], A.-M. Gheorghe[2], A.-I. Trandafir[2], E. Petrova[3]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital, Bucharest, Romania; [2]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [3]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Hypoparathyroidism following thyroidectomy is still a significant issue despite advancement of surgical techniques and patient preparation. The resulting hypocalcemia ranges from asymptomatic biochemical variations to severe tetany [1-8]. We aim to introduce such patient.
Method: case report. Ethical approval was no. 29336 from 10/17/2025.
Results: A 49-year-old female was diagnosed with multinodular goiter with a dominant nodule in the left thyroid lobe of 2.3 cm, hypoechoic, vascularized and with microcalcifications. Her personal medical history also included a uterine myoma of 3.4cm diagnosed 3 months prior with negative tumor markers. She successfully underwent total thyroidectomy and pathological report revealed a papillary thyroid microcarcinoma. Subsequently, she presented with paresthesia and muscle cramps and thyroid panel showed Thyroid Stimulating Hormone 0.62µIU/mL(normal: 0.35-4.94), free levothyroxine 15.87pmol/L(normal: 9-19)] under 100µg levothyroxine/day. Parathormone was decreased 14.9pg/mL(normal: 17.3-74.1), low-normal blood calcium 8.5 mg/dL(normal: 8.5-10.2), phosphorus 2.9mg/dL(normal: 2.5-4.5) and low 25-hydroxyvitamin D 25ng/mL(normal: >30). Bone turnover markers showed decreased osteocalcin 10.7ng/mL(normal: 15-46), normal alkaline phosphatase 58IU/L(normal: 38-105), P1NP 34.7ng/mL(normal: 20.25-76.31) and CrossLaps 0.397ng/mL(normal: 0.33-0.782). After 4 days of intravenous calcium gluconate 1g/day the symptoms remitted and she was recommended oral calcium supplements 1.2g/day in addition to cholecalciferol 2000IU/day and alphacalcidol 1µg/day.
Conclusion: Prompt and adequate treatment of post-surgical hypoparathyroidism can minimize the severity of clinical manifestations and long-term consequences of hypocalcemia in these cases.

Objective: Cushing's disease is associated with increased fracture risk even in young male patients [1-6]. We aim to introduce a case of post-thyroidectomy hypocalcemia in a subject with relapsed Cushing's disease.
Method: case report. Ethical approval was no. 29336 from 10/17/2025.
Results: A 40-year-old male had a history of microadenoma-related Cushing's disease diagnosed at 33. He underwent trans-sphenoidal hypophysectomy followed by secondary adrenal insufficiency under substitution with prednisone that remitted in 6 months and remained in Cushing's disease remission for 4 years. Currently,biochemical and hormonal relapse of Cushing's disease was found: adrenocorticotropic hormone 64.78pg/mL (normal: 7.2-63.3), plasma cortisol after 2x2mg dexamethasone suppression test 14.74µg/dL, after 2x8mg dexamethasone suppression test 5.08µg/dL, 24-hour free urinary cortisol 428.4µg/24h (normal: 4.3-176), complicated with type 2 diabetes mellitus, arterial hypertension and hypogonadism. In addition, neck ultrasound showed a hypoechoic thyroid nodule of 2.6 cm in the right lobe. He underwent total thyroidectomy and pathological report confirmed a follicular adenoma. Postoperatory, he experienced hypocalcemia with blood calcium 8.35mg/dL(normal: 8.8-10.6), low 25-hydroxyvitamin D 27.85ng/mL (normal: >30) and normal parathormone. Bone formation markers were suppressed: osteocalcin 2.27ng/mL (normal: 14-42), P1NP 6.99ng/mL (normal: 20.25-76.21) and bone resorption was normal: CrossLaps 0.25ng/mL (normal: 0.182-0.801). Beside calcium, vitamin D supplements and levothyroxine 100µg/day, he was recommended Pasireotide LAR 10mg/month and oral antidiabetic and antihypertensive drugs.
Conclusion: The concomitant presence of hypercortisolism, hypogonadism, type 2 diabetes mellitus and mineral metabolism

disturbances represents a constellation of factors that deteriorate bone health.

Background: Risk factors for seroma formation after total thyroidectomy include local aspects such as the extent of surgery and systemic contributors such as postsurgical hypocalcemia and hypoparathyroidism. We aim to introduce a case of cervical seroma following thyroid cancer surgery [1-6].
Method: case report. Ethical approval no. 29336 from 10/17/2025.
Results: A 33-year-old male presented as an emergency for left anterior cervical pain and compressive symptoms during the past 2 days. He was diagnosed with a thyroid nodule of 3 cm in the left lobe 2 years prior to admission. Currently, thyroid ultrasound confirmed the nodule with increased size of 4.7 cm and tracheal deviation to the right, while computed tomography revealed extension to the jugular notch. He underwent total thyroidectomy with pathological report of papillary thyroid microcarcinoma. One week later, clinical examination revealed an anterior cervical swelling with local erythema. At neck ultrasound he had 3 subcutaneous hypoechoic fluid collections anterior to the trachea of 2.8 cm, left paramedian of 3.9 cm and right paramedian of 2.1 cm indicating postsurgical seroma. Thyroid Stimulating Hormone was 2.48μIU/mL (normal: 0.35-4.94) under levothyroxine 100μg/day with negative thyroglobulin and anti-thyroglobulin antibodies. Total serum calcium was 9.7mg/dL (normal: 8.5-10.2), low 25-hydroxyvitamin D 16.7ng/mL (normal: 30-100) and normal parathormone 50.08pg/mL (normal: 17.3-74.1). Needle aspiration of the seroma was performed with complete remission and no subsequent re-accumulation. Vitamin D supplementation with cholecalciferol 2000 UI/day was initiated.
Conclusion: Postsurgical evaluation of mineral metabolism may provide additional information for the patient's risk of seroma accumulation. In this case, vitamin D deficiency may contribute to impaired tissue healing and fluid accumulation.

Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective. Angiopoietin-like 4 (ANGPTL4), a key regulator of lipids metabolism, is connected to glucose control. An interplay with adipogenic-osteogenic differentiation balance is proposed, been a promising alternative as future candidate against osteoporosis. The bone connection is either direct or by multiple signalling pathways (inflammation, insulin resistance, adipokines-related lipids influence). We aim to analyse ANGPTL4 in obese vs non-obese women in relationship with mineral metabolism, DXA-BMD and other adipokines.
Methods. This is an exploratory, bi-centric study. Ethical

approvals: no.32/09/30/2024 and no.97/11/20/2024 (PN-IV-P8-8.3-ROMD-2023-0262). Inclusion criteria: menopause, age ≥50. Exclusion criteria: diabetes, dyslipidaemia, cancers, kidney, bone (e.g. osteoporosis) and metabolic disorders (other than obesity). Study protocol: fasting blood testing of glycaemia, mineral metabolism assays [e.g. 25-hydroxivitamin D (25OHD)], and adipokines based on ELISA detection (Quantibody® Human Obesity Array 3, RayBiotech, Inc, Norcross, GA, USA, QAH-ADI-3, inter-assay precision<20%). Central DXA (GE Lunar Prodigy) and 75-gram oral glucose tolerance test (providing 2-h glycaemia) were performed.

Results

12 women with obesity (BMI ≥30kg/m^2, 32.83±1.47 kg/m^2) vs 12 females with non-obesity (BMI<30 kg/m^2,23.61±2.70 kg/m^2, p<0.001) had similar age (60.00±7.15 vs. 53.88±6.98 years, p=0.1), 2-hour glycaemia (155 vs 112 mg/dL, p=0.21), and DXA-BMD (g/cm^2) at lumbar spine (0.998±0.165 vs 1.029±0.142, p=0.6), femoral neck (0.998±0.165 vs 1.029±0.142, p=0.6), and total hip (0.958±0.08 vs 0.904±0.41, p=0.2). Obesity group had lower 25OHD (26.8 vs 34.35 ng/mL, normal<30, p=0.015), and, after adjustment, lower ANGPTL4: [mean(95%CI): 16.03(16.4673.44) vs 47.62(12.78, 25.19) ng/mL, p=0.003).Obesity group: ANGPTL4 correlated with interleukin-10 (pg/mL): r=0.9, p<0.0001. Non-obesity group: ANGPTL4 negatively correlated with serum phosphorus (mg/dL): r= -0.711, p=0.0142, and positively with tumour necrosis factor receptor I (ng/mL): r=0.75, p=0.0522.

Conclusion. ANGPTL4 is lower in obese vs age- and 3-sites BMD-matched, non-obese menopausal women. ANGPTL4 showed no direct correlation with DXA-BMD, or mineral metabolism assays, except for an inverse relationship with phosphorus in non-obese females, which suggests a distinct significance based on BMI (as found for the adipokines panel).

DIAGNOSTIC PITFALLS OF A NEARLY-COMPLETELY CALCIFIED THYROID NODULE IN A YOUNG FEMALE: DOES THE MINERAL METABOLISM COUNT?

M. Costachescu[1], A.-M. Gheorghe[2], O.-C. Sima[2], A.-I. Trandafir[2], E. Petrova[3]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital, Bucharest, Romania; [2]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [3]Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Thyroid nodules with near-complete calcification may be long-standing benign lesions, but malignancy cannot be excluded. Moreover, ultrasonographic suspicious features might be hidden by the extensive calcification and fine-needle aspiration(FNA) can be technically limited. We aim to introduce a case of a near-completely calcified thyroid nodule associated with compressive symptoms [1-5].

Method: case report. Ethical approval was no. 29336 from 10/17/2025.

Results: A 45-year-old female was admitted for thyroid evaluation due to mild compressive symptoms. She was known with a right thyroid nodule of 2.6 cm with cystic degeneration since the age of 43. On admission, thyroid function was normal with Thyroid Stimulating Hormone 1.09µIU/mL(normal: 0.35-4.94), free levothyroxine 14.88pmol/L(normal: 9-19), increased calcitonin 6.13pg/mL(normal: 1-4.8) and negative anti-thyroid antibodies. Blood calcium was normal 9.1mg/dL(normal: 8.5-10.2), as well as phosphorus 3.9mg/dL(normal: 2.3-4.7) and parathormone 35.81pg/mL(normal: 17.3-74.1) with decreased 25-hydroxyvitamin D 22.47ng/mL(normal: >30). Bone turnover markers were within normal range. Thyroid ultrasound showed the right lobe with an almost entirely calcified nodule of 2.8 cm with a protrusive area towards the upper part of the thyroid, in close contact with the anterior thyroid capsule. Computed tomography confirmed the right lobe nodule with almost total calcification that protruded from the thyroid contour. Ultrasonographic malignancy criteria were unclear and FNA was considered with low rate of success because of the massive calcification, hence she was referred to total thyroidectomy. Vitamin D supplementation with cholecalciferol 2000IU/day was also recommended.

Conclusion: In this case, the absence of reliable ultrasound imaging and cytological assessment in the presence of compressive symptoms pointed towards surgical treatment despite indeterminate malignancy criteria.

COMPLETE MANAGEMENT IN WOMEN WITH OSTEOPOROSIS AND LOCOMOTIVE SYNDROME

A.-M. Mehedintu[1], M. A. Matei[2], D. Matei[3], R. Traistaru[3]

[1]University of Medicine and Pharmacy , Doctoral School, Craiova, Romania; [2]University of Valencia, Faculty of Medicine, Valencia, Spain; [3]University of Medicine and Pharmacy, Craiova, Romania

Background. Locomotive Syndrome (LoS) describes mobility limitations (walking, sit-to-stand, stair climbing, activities of daily living) caused by impairment of the locomotive organs and is associated with a higher risk of future need for nursing care. Osteoporosis and other musculoskeletal disorders frequently contribute to LoS.

Aim. To evaluate whether a *complete management* strategy combining medication plus a standardized rehabilitation program improves pain and functional status more than medication alone in older women with LoS and osteoporosis.

Methods. Forty-eight elderly *female* LoS patients (71–80 years), all diagnosed with osteoporosis and previously diagnosed with early lumbar spinal stenosis and osteoarthritis, were fully assessed and categorized as LoS Stage 1 or 2. Participants were randomized equally to an

experimental group (EG: medication + rehabilitation) or a control group (CG: medication only). Rehabilitation included TENS, deep oscillation therapy, and mixed kinetic training (resistance, aerobic, proprioceptive exercises) delivered daily for 12 sessions, followed by an adapted home-training program. Outcomes were assessed at baseline and post-rehabilitation: pain (VAS), functional independence (Katz ADL index), and 25-question Geriatric Locomotive Function Scale (GLFS-25). Analyses were performed using SPSS 22.0.

Results. Both groups showed improvement after rehabilitation. Pain reduction was greater in EG, with significant decreases in VAS in EG ($p < 0.001$) and CG ($p = 0.004$), and a statistically significant between-group difference post-intervention ($p < 0.05$). Functional outcomes improved significantly in EG, with post-rehabilitation between-group differences reaching statistical significance ($p < 0.05$), particularly for VAS and Katz index.

Conclusions. In older women with osteoporosis and LoS, rehabilitation improves pain and function, while adding medication may provide additional benefit—especially for pain reduction and ADL independence—potentially enhancing quality of life and supporting strategies aimed at slowing LoS progression.

ACUTE ANTERIOR UVEITIS FOLLOWING ZOLEDRONIC ACID ADMINISTRATION: A CASE REPORT

M. C. K. Calkin Korkmaz[1], Z. Yasar Aydin[1], S. H. Haliloglu[1], M. K. A. Karacaatli Erdogan[1], B. A. Akdan[1]

[1]Kartal Dr. Lütfi Kırdar City Hospital, Istanbul, Türkiye

Introduction:
Bisphosphonates are widely used and well-established agents in the treatment of postmenopausal osteoporosis due to their efficacy in reducing bone resorption and fracture risk. Intravenous zoledronic acid is frequently preferred because of its potent antiresorptive effect and convenient once-yearly administration. Although bisphosphonates are generally well tolerated, rare but potentially serious inflammatory ocular adverse effects have been reported. These include anterior uveitis, episcleritis, scleritis, and, less commonly, optic neuritis. Awareness of such complications is essential, particularly in patients with a prior history of ocular or neurologic inflammatory disease.

Case Report:
A 65-year-old woman was evaluated for postmenopausal osteoporosis. Dual-energy X-ray absorptiometry revealed a T-score of −3.0 at the total femur and lumbar spine (L1–L4). After exclusion of secondary causes of osteoporosis, intravenous zoledronic acid therapy was initiated. Approximately 24 hours after infusion, the patient developed sudden-onset unilateral severe eye pain accompanied by photophobia and blurred vision. She was promptly referred to ophthalmology. The diagnosis of acute anterior uveitis was established. Comprehensive evaluation for infectious, rheumatologic, and systemic inflammatory causes was unremarkable, and no alternative etiology was identified.

The patient showed gradual clinical improvement, with complete resolution of ocular inflammation and full recovery of visual acuity. No recurrence was observed during follow-up.

Discussion:
Bisphosphonate-associated ocular inflammation is rare but clinically significant. Acute anterior uveitis is the most frequently reported manifestation and typically occurs within 24–72 hours after drug administration, with intravenous formulations carrying a higher risk than oral agents. Although the exact pathophysiological mechanism remains unclear, activation of γδ T lymphocytes and subsequent proinflammatory cytokine release are thought to play a role. Patients with a history of uveitis or optic neuritis, including those with demyelinating diseases such as multiple sclerosis, may be particularly susceptible. This underscores the importance of careful ophthalmologic and neurologic history-taking prior to bisphosphonate initiation.

Conclusion:
This case highlights acute anterior uveitis as a rare but serious adverse effect of zoledronic acid. Clinicians should exercise caution when prescribing bisphosphonates to patients with a history of ocular inflammation or optic neuritis and consider alternative osteoporosis treatments in high-risk individuals.

P314

CORRELATION BETWEEN THE HEALTH STATUS OF ADULT PATIENTS WITH OSTEOARTHRITIS WITH THEIR FAMILY APGAR SCORES

B. A. Gelle[1], K. Floro-Cruz[1], R. O. Cruz[1], R. Juangco[1]

[1]Perpetual Help Medical Center Las-Pinas, Las-Pinas, Philippines

Title:Correlation between the Health Status of Adult patients with Osteoarthritis with their FamilyAPGAR scores.

Authors: Brian Alison S. Gelle, Kathryn Floro-Cruz, Raymond Oliver A. Cruz, Jose Ronilo G. Juangco

Abstract

Background: Osteoarthritis (OA) is a highly prevalent musculoskeletal disease, severely impacting functional capacity and quality of life (QOL). Given the chronic nature of OA and its associated QOL deterioration, understanding the role of social support, particularly family function, is essential for comprehensive patient care.

Objective: This study determined the correlation between the health status (symptoms and QOL) of adult OA patients and their family functionality, as measured by the WHOQOL-BREF, WOMAC, and Family APGAR.

Methodology: A quantitative, correlational study was conducted on 50 adult OA patients via purposive sampling. Instruments used were the WHOQOL-BREF (QOL), WOMAC (symptoms), and Family APGAR (family function). Data were analyzed using Pearson's r.

Results: Participants reported moderate OA pain (M=8.06) and stiffness (M=3.64), with Physical Health scoring lowest on the WHOQOL-BREF (M=66.41). Most participants (68.00%) reported a Highly Functional Family. Family functionality showed a statistically significant moderate positive correlation with the **Psychological** (r=0.3880), **Environment** (r=0.4507), and **Overall QOL** (r=0.4230) domains. No significant correlation was found with the objective WOMAC physical domains (Pain, Stiffness, Physical Function).

Conclusion: A functional family unit acts as a crucial protective psychosocial factor. Family support does not alter the objective severity of OA symptoms but significantly improves the patient's emotional well-being and overall QOL perception. This highlights the necessity of incorporating family-centered interventions into the comprehensive management of osteoarthritis.

Keywords: Humans (H), Adult (A), Middle Aged (MA), Quality of Life (QOL), Family Support, Outpatients, Osteoarthritis(OA), Pain, Health Status

P315

ASSOCIATION BETWEEN SARCOPENIA AND FAILURE OF VERTEBRAL AUGMENTATION FOR OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES: DOES VITAMIN D STATUS MATTER?

B. Abay[1], H. Mraja[2], M. Enercan[2], A. Hamzaoglu[2]

[1]Department of Orthopedic Surgery and Traumatology, Demiroglu Bilim University, Istanbul, Türkiye; [2]Department of Orthopedic Surgery and Traumatology, Istanbul Florence Nightingale Hospital, Istanbul, Türkiye

Objective:
Osteoporotic vertebral compression fractures (OVCFs) remain a major cause of pain and disability in aging populations, with vertebral augmentation limited by postoperative complications. Sarcopenia and vitamin D deficiency, common contributors to skeletal fragility, may impair bone–muscle integrity and healing. This study investigates whether sarcopenia and serum vitamin D status predict mechanical failure following vertebral augmentation for OVCFs.

Material and Methods:
This retrospective single-center cohort included 124 patients aged >60 years who underwent percutaneous kyphoplasty (KP) or vertebroplasty (VP) for OVCFs between 2012 and 2025. Patients with secondary osteoporosis, malignancy, or spinal infection were excluded. Sarcopenia was assessed on preoperative CT using the cross-sectional area of the psoas muscle at the L3 level, normalized by height (cm^2/m^2), with established sex-specific cut-off values. Bone mineral density (BMD) was measured by quantitative CT (QCT), and T-scores were recorded from the lumbar region. Serum 25-hydroxyvitamin D [25(OH)D] levels obtained within 3 months were classified as deficient (<20 ng/mL), insufficient (20–29 ng/mL), or sufficient (≥30 ng/mL). The primary outcome was augmentation failure, defined as new or adjacent refracture, revision surgery, or ≥5 mm anterior vertebral height loss at 12 months. Secondary outcomes included residual back pain (VAS ≥4) and 1-year mortality. Multivariate logistic regression and Cox models assessed predictors, including an interaction term (sarcopenia × vitamin D category).

Results:
A total of 124 patients (mean age 71.8 ± 6.9 years; 97 females, 27 males) were analyzed. Sarcopenia was present in 56 patients (45.2%), and vitamin D deficiency (<20 ng/mL) in 74 (59.7%). The mean lumbar QCT T-score was −3.1 ± 0.6. Augmentation failure occurred in 28 patients (22.6%): 19/56 with sarcopenia (33.9%) versus 9/68 without (13.2%, p = 0.008). Failure was higher in vitamin D–deficient patients (22/74, 29.7%) compared with sufficient ones (6/50, 12.0%, p = 0.021). Combined sarcopenia and vitamin D deficiency showed the highest failure rate (38.2%, OR 3.4, 95% CI 1.3–8.9, p = 0.04).

Conclusion:
Sarcopenia and vitamin D deficiency were significant predictors of mechanical failure after vertebral augmentation in OVCFs. Patients with both conditions had the highest risk of refracture and height loss, underscoring the combined effect of muscle and metabolic fragility on surgical outcomes. These findings support routine preoperative assessment of muscle mass and vitamin D status; prospective studies should test whether targeted optimization reduces failure and improves long-term recovery.

Keywords: sarcopenia, vitamin D, vertebral augmentation, kyphoplasty, osteoporotic fractures

P316

ASSOCIATION BETWEEN SARCOPENIA AND LOW VITAMIN D LEVELS WITH IMPLANT FAILURE AFTER HIP FRACTURE SURGERY: A SINGLE-CENTER RETROSPECTIVE STUDY

B. Abay[1], Y. Atalay[2], H. Mraja[2], M. Enercan[1], I. Ozturk[1], A. Hamzaoglu[2]

[1]Department of Orthopedic Surgery and Traumatology, Demiroglu Bilim University, Istanbul, Türkiye; [2]Department of Orthopedic Surgery and Traumatology, Istanbul Florence Nightingale Hospital, Istanbul, Türkiye

Background
Sarcopenia are highly prevalent in elderly patients with osteoporotic hip fractures and are linked to increased mortality and poorer functional outcomes. However, their relationship with mechanical failure of internal fixation remains unclear.

Objectives
This study aimed to evaluate whether CT-defined sarcopenia and low serum 25-hydroxyvitamin D [25(OH)D] levels are associated with implant failure after osteosynthetic treatment of osteoporotic hip fractures.

Study Design & Methods
A retrospective cohort study was conducted on patients ≥ 60 years who underwent proximal femoral nail antirotation (PFN-A) or lag screw fixation for low-energy intertrochanteric or femoral-neck fractures (2015–2025). Exclusion criteria included pathologic or high-energy fractures, malignancy, and revision surgery.
Sarcopenia was determined using the cross-sectional area of the psoas major at L3 on preoperative CT images (normalized for height; lowest sex-specific tertile = sarcopenic). Serum 25(OH)D levels within 1 month of surgery were categorized as deficient < 20 ng/mL, insufficient 20–29 ng/mL, sufficient ≥ 30 ng/mL.
Implant failure was defined as cut-out, varus collapse > 5°, or revision surgery within 12 months. Radiographic parameters, fracture classification (AO/OTA), reduction quality, and Tip–Apex Distance (TAD) were recorded. Logistic regression assessed associations between sarcopenia, vitamin D status, and implant failure after adjusting for age, sex, BMI, BMD, TAD, and fracture type.

Results
142 patients (mean age 66.2±5.4 years, 88 female, 54 male), sarcopenia prevalence was 43 %, and vitamin D deficiency 62 %. Mechanical failure was observed in 26 patients, 18 % in postoperative 12 months. We hypothesize that sarcopenic patients with deficient vitamin D will show a threefold higher odds of implant failure (adjusted OR ≈ 3.2, p < 0.05) compared to non-sarcopenic, vitamin-D-sufficient counterparts. A significant interaction effect (p < 0.05) between sarcopenia and vitamin D status was observed.

Conclusions
Both sarcopenia and vitamin D deficiency may independently and synergistically predict early mechanical failure after hip fracture fixation, suggesting that combined "osteosarcopenia" markedly effects fixation stability. Preoperative assessment and optimization of muscle mass and vitamin D levels could improve fixation longevity and functional recovery in osteoporotic patients.

P318

RESISTANT SECONDARY OSTEOPOROSIS FOLLOWING ADOLESCENT-ONSET ANOREXIA NERVOSA IN A YOUNG WOMAN: A CASE REPORT

B. Cinar[1], P. Oztop Ciftkaya[1], E. Bilgin[1]

[1]Basaksehir Cam and Sakura City Hospital, Department of Physical Medicine and Rehabilitation, İstanbul, Türkiye

Objective
To highlight that anorexia nervosa with onset during adolescence may lead to severe, resistant secondary osteoporosis at a young age.

Materials and Methods
Clinical data, laboratory results, serial dual-energy X-ray absorptiometry (DXA) measurements, and radiological imaging of a young female patient followed for osteoporosis and presenting with back pain were retrospectively evaluated.

Results
A 29-year-old woman presented with back pain and had been followed with a diagnosis of osteoporosis. Her medical history revealed a diagnosis of anorexia nervosa at the age of 16, with disordered eating behaviors developing after psychosocial body image pressure during adolescence. Her pre-illness height and weight were reported as 172 cm and 58 kg. At presentation, her height was 161 cm and body weight was 44 kg. She had a history of secondary amenorrhea; however, regular menstrual cycles had resumed over the past three years with medical management. She had no history of smoking or alcohol use, and no other cause of secondary osteoporosis was identified. Serum calcium and 25-hydroxyvitamin D levels were within normal ranges.
The patient was diagnosed with osteoporosis in 2022 and had been treated with alendronate and denosumab during follow-up. Despite treatment, serial DXA measurements demonstrated persistently low bone mineral density with Z-scores below −2 in the lumbar spine and femoral regions. Previous imaging revealed osteoporotic compression fractures at the T6, T7, and T12 vertebrae. At presentation lateral thoracic spine radiographs demonstrated a compression fracture at the T3 vertebra. Additionally, she sustained a low-trauma hip fracture requiring surgery.

Conclusion
This case demonstrates that anorexia nervosa may result not only in reduced bone mineral density but also in a multidimensional clinical picture characterized by recurrent vertebral fractures, height loss, low-trauma hip fracture, secondary amenorrhea, and functional impairment. Disease progression despite antiresorptive therapy suggests that bone loss associated with anorexia nervosa may be resistant. Therefore, anorexia nervosa should be considered in the etiology of secondary osteoporosis in young individuals, and bone health should be evaluated early using a comprehensive approach.

P319

PATHOLOGICAL FRACTURE FROM OSTEOSARCOMA ARISING IN POLYOSTOTIC PAGET DISEASE OF BONE: A CASE REPORT

B. Dhamo[1]

[1]Hygeia Hospital Tirana, Tirana, Albania

Background: Paget disease of bone (PDB) is a chronic skeletal disorder characterized by excessive and disorganized bone remodeling. Although the condition is generally benign, malignant transformation—most commonly to osteosarcoma—occurs in fewer than 1% of cases. Such tumors are aggressive, rapidly progressive, and often present initially with pathological fractures.

Case Presentation: A 55-year-old woman presented with acute left arm pain and functional impairment following a low-energy fall. Radiographs demonstrated a displaced pathological fracture through a humeral lesion exhibiting mixed lytic–sclerotic changes consistent with PDB. Laboratory studies revealed markedly elevated alkaline phosphatase, and whole-body scintigraphy confirmed polyostotic involvement. Biopsy established the diagnosis of high-grade osteoblastic osteosarcoma. The patient received neoadjuvant cisplatin–doxorubicin chemotherapy and zoledronic acid, with partial biochemical but minimal radiologic response. Due to extensive local disease, amputation was performed. She completed postoperative chemotherapy and continues under multidisciplinary surveillance.

Conclusion: Osteosarcoma arising from polyostotic PDB is a rare, life-threatening complication. Pathological fracture may be the first indicator of malignant degeneration. Early biopsy, careful radiologic evaluation, and coordinated oncologic management are crucial to improving outcomes

P320

HIP FRACTURES IN THE AGING GLOBAL POPULATION: AN ESCALATING PUBLIC HEALTH CRISIS

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Abstract
Objective: This study aimed to systematically assess the global burden of hip fractures among adults aged ≥70 years from 1990 to 2021, focusing on incidence, prevalence, and years lived with disability (YLDs), and to evaluate trends, socioeconomic drivers, and future projections to inform targeted public health strategies.
Methods: Using data from the Global Burden of Disease (GBD) 2021 study, we analyzed incidence, prevalence, and YLDs rates for hip fractures in adults ≥70 years across 204 countries and territories. Analyses were stratified by age, sex, sociodemographic Index (SDI), and region. Statistical methods included estimating average annual percentage changes (EAPCs), frontier efficiency analysis, decomposition analysis, and forecasting models (ARIMA and exponential smoothing) to project trends to 2050.
Results: In 2021, there were 10.97 million new cases, 21.59 million prevalent cases, and 1.91 million YLDs globally among adults ≥70 years

or older. From 1990 to 2021, incidence and prevalence rates increased significantly (EAPCs: 0.62 and 0.83, respectively). The burden was higher in women and peaked in those aged ≥95 years. High SDI regions carried the highest absolute burden, but the most rapid growth occurred in middle SDI regions. Decomposition analysis identified population growth as the primary driver of increased burden (76.95–97.97% of the increase), followed by population aging. Frontier analysis revealed significant efficiency gaps in several high SDI countries (e.g., the US, Australia). SDI showed a strong positive correlation with burden rates, particularly above a threshold of 0.75. Forecasts indicated a persistently higher burden for women by 2050.

Conclusion: The burden of hip fractures in older adults is substantial, increasing, and unevenly distributed across demographics and regions. Effective public health strategies must address high-risk groups (e.g., women, very elderly) and regions (high and middle SDI) through improved prevention, early screening, and optimized resource allocation.

Keywords: Hip fracture, elderly, disease burden, GBD study, incidence, prevalence, YLDs, SDI, global health

P321

GLOBAL, REGIONAL AND NATIONAL BURDEN OF KNEE OSTEOARTHRITIS 1990-2021: A SYSTEMATIC ANALYSIS OF THE GLOBAL BURDEN OF DISEASE STUDY 2021

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Objective: The systematic analysis aimed to assess the levels and trends of knee osteoarthritis (KOA) in 204 countries and territories from 1990 to 2021.

Methods: We analyzed the data on the Global Burden of Diseases 2021 and reported the KOA burden and the trends from 1990-2021 by age-standardized incidence rate (ASIR), age-standardized prevalence rate (ASPR) and disability-adjusted life years (DALYs). All estimates were presented as counts and age-standardized rates per 100,000 people, calculating the estimating average annual percent change (EAPCs) with 95% uncertainty intervals (UIs).

Results: From 1990 to 2021, the KOA burden still showed an increasing trend globally, faster in females than males; the 35-39 years population has faster KOA symptoms, and 45-49 years have faster prevalence and DALYs. The high-middle SDI regions are experiencing the fastest increase. East Asia has the fastest growth, and North America has shown a stable trend with no change. The top 9 fastest growing countries and territories were Oman, Equatorial Guinea, Thailand, Saudi Arabia, Sudan, China, Taiwan (Province of China), Maldives, and Pakistan. By 2050 of prediction, there may be an obvious decreasing trend in KOA burden. Frontier analysis indicates the presence of unrealized opportunities to close the KOA burden gap in most countries and territories. Decomposition analyses indicate that population growth accounted for more than 70% of the global KOA burden. SDI level was positively associated with KOA burden increasing, and ASIR or HDI was not associated with the burden EPAC.

Conclusion: KOA is still a major global health challenge. Although there is variation between countries and regions, most countries' KOA burden is increasing, especially among females and young adults.

Keywords: Knee osteoarthritis, Burden, Trend, Incidence, Prevalence, DALYs

P322

EVALUATION AND MANAGEMENT STRATEGIES OF ACETABULAR SIDE OSTEOLYSIS AFTER TOTAL HIP ARTHROPLASTY

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Background

The wear of the liner after total hip arthroplasty (THA) is an important cause of prosthesis loosening, and the long-term wear of the liner often leads to a large amount of osteolysis around the prosthesis. Osteolysis is different from simple bone defect. The remaining cancellous bone is in a state of osteoporosis, and the cortical bone often loses its function. For such a large range of osteolysis, how to perform revision has always been a major challenge that troubles orthopedic joint surgeons. This study aims to review the cases of acetabular side osteolysis in the recent three years, and carry out treatments such as traditional revision, bone grafting + revision, and revision with 3D printed prostheses for cases of osteolysis with different ranges, so as to provide new ideas for the treatment of clinical cases of acetabular side osteolysis.

Methods

This study collected THA patients with different degrees of osteolysis caused by the wear of the polyethylene liner from 2020 to 2023, and a total of 49 patients were collected. Preoperative X-ray and CT (computed tomography) scans were performed to determine the range and degree of osteolysis, and the cases of osteolysis caused by periprosthetic infection were excluded. A retrospective analysis was carried out on 49 patients (52 hips) with acetabular osteolysis treated during THA revision surgery. According to the Paporsky classification, there were 5 hips of type I, 34 hips of type II, and 13 hips of type III. Methods such as biological large acetabular cups, biological acetabular cups + cancellous bone particle grafting, and customized prostheses were used to repair patients with different types of bone defects. Regular follow-up was carried out after the operation. The Harris method was used to evaluate the hip joint function, and the X-ray film was used to determine whether the prosthesis was loose and whether the transplanted bone was integrated.

Results

The 49 patients presented with hip pain symptoms on average 14.7 years after the primary replacement surgery. Among them, there were 12 cases in the traditional revision group, 28 cases of bone grafting + revision, and 9 cases of revision with 3D printed prostheses. All 49 patients were followed up, with an average follow-up period of 23 months (ranging from 5 to 33 months). The average Harris score after the operation was 81.7 points, which was an average improvement of 41.3 points compared with that before the operation. One hip required re-revision due to dislocation, and the rest had good results. There was no loosening or subsidence of the prosthesis on the X-ray film, and continuous trabecular bone could be seen passing through the junction of the transplanted bone and the host bone.

Conclusion

In the THA revision surgery caused by osteolysis, for a small range of osteolysis, traditional revision with a large cup can be adopted; for moderate bone defects, bone grafting + revision can achieve good prosthesis stability; for a large range of osteolysis or large defects affecting the prosthesis stability, the method of using 3D printed customized prostheses can achieve good results.

P323

3D PRINTED ACETABULAR PROSTHESIS FOR PAPROSKY Ⅲ TYPE BONE DEFECTS IN THA REVISIONS

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Background
The utilization of 3D-printed prostheses has witnessed a growing trend in the acetabular revision procedures of total hip arthroplasty (THA), particularly in cases characterized by irregular and extensive bone defects or osteolysis. This research was designed to assess the mid-term performance of 3D-printed prostheses in THA revision.
Methods
Conducted as a retrospective study, it involved the screening of patients undergoing aseptic revision THA due to prosthesis loosening and acetabular bone defects from May 2023 to December 2024. The study specifically focused on including those patients who received 3D-printed acetabular prostheses. Demographic information of the enrolled patients was systematically gathered for analysis.
Results
Totally, there were 19 patients who underwent acetabular revision with 3D-printed prostheses were recruited for this study. The average age of the participants was 65.34 years, ranging from 57 to 81 years old. The mean follow-up duration was 15.4 months, spanning from 6 to 23 months. Eleven hips presented with Paprosky ⅡA type defects, and eight cases had type ⅡB defects. At the final follow-up, all the prostheses in the 3D-printed group remained firmly fixed, achieving an implant survival rate of 100%.
Conclusion
This study has shown that the application of 3D-printed prostheses in THA revision yields favorable mid-term clinical and radiological results.

P324

THE ASSOCIATION BETWEEN MONOCYTE-TO-ALBUMIN RATIO AND LONG-TERM MORTALITY IN GERIATRIC HIP FRACTURE: A RETROSPECTIVE COHORT OF 2115 PATIENTS

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Objective: This retrospective study evaluated the association between monocyte-to-albumin ratio (MAR) and long-term mortality in geriatric hip fractures.
Methods: We collected the demographic and baseline information of geriatric patients with hip fractures in our hospital, and followed up on the survival data. Multivariate Cox proportional hazards regression model, restricted cubic spline, and propensity score matching (PSM) methods were used to identify the linear and non-linear associations between MAR and long-term mortality.
Results: Two thousand one hundred and fifteen patients were included in this study, with a mean age of 79.36±6.74 years. There were 672 males and 1443 females, 1529 intertrochanteric fractures, and 586 femoral neck fractures. The patients were divided into three subgroups: 731 low MAR (9.23±2.17) group, 693 medium MAR (14.48±1.47) group, and 691 high MAR (22.48±5.35) group. The mean follow-up period was 38.57 months. Duration of the follow-up, there were a total of 636 all-cause deaths, 198, 184, 254 in the low, medium, and high MAR groups, respectively. The study found a U-shaped association between MAR and mortality, and 10.37 was an inflection point. When MAR was less than 10.37, every one-unit increase in MAR, the mortality of patients decreased by 6% (HR=0.94; 95%CI: 0.88-0.99; *P*=0.0322). When MAR was greater than 10.37, every one-unit increase in MAR, the mortality of patients increased by 1% (HR=1.01, 95%CI:1.00-1.03; *P*=0.0175). In the PSM and models, we found that the results were stable and the inflection point was 10.39 and 10.36, respectively.
Conclusion: This study demonstrates that the MAR exhibits a U-shaped association with long-term mortality in geriatric hip fracture patients, with an optimal balance observed at MAR=10.37. The association reflects the interplay between monocyte inflammatory activation and nutritional albumin reserve. MAR is a composite biomarker identifying high-risk populations and guiding individualized management strategies targeting inflammation-nutrition balance.

P325

THE URIC ACID TO HDL-C RATIO AS A NOVEL PREDICTOR OF MORTALITY IN ELDERLY HIP FRACTURE PATIENTS: A STUDY REVEALING A SATURATION EFFECT

B. F. Zhang[1]

[1]Xi'an Jiaotong University, Xi'an, China

Objective: To investigate the association between the uric acid to high-density lipoprotein cholesterol ratio (UHR) and long-term all-cause mortality in elderly patients with hip fractures.
Methods: We collected demographic and baseline information from geriatric patients with hip fractures aged 65 years or older who were admitted to our hospital. The UHR was calculated from admission laboratory data. The primary endpoint was all-cause mortality during the follow-up period. The relationship between UHR and mortality was analyzed using multivariate Cox proportional hazards regression models, with restricted cubic splines and a two-piecewise model to explore potential nonlinearity and identify an inflection point.
Results: We included 304 patients in this study, 104 males and 200 females. The mean age was 80.00±6.50 years. The mean follow-up period was 34.42±14.76 months, and there were 82 all-cause deaths. A nonlinear relationship was observed between UHR and mortality, with an inflection point at UHR = 166.17. Below this threshold, a 1-unit increase in UHR was significantly associated with a 1% increase in mortality risk (HR = 1.01, 95% CI: 1.00-1.03, P = 0.0326). Above this threshold, no significant association was found (HR=1.00, 95% CI: 1.00-1.00, *P*=0.8050). After adjusting for multiple confounders, UHR remained an independent predictor of mortality, indicating a "saturation effect."
Conclusion: UHR is an independent predictor of long-term mortality in elderly patients with hip fractures, exhibiting a nonlinear relationship characterized by a saturation point. Further prospective studies are needed to validate the UHR threshold and assess its clinical utility.
Keywords: Uric acid; High-density lipoprotein cholesterol; Hip fractures; Elderly; Mortality; Prognostic biomarker; Nonlinear relationship.

CAN WE SLOW THE BONE? ZOLEDRONIC ACID IN CRANIOFACIAL POLYOSTOTIC FIBROUS DYSPLASIA

B. Fernandes Esteves[1,2], M. Correia Natal[1,2], M. Oliveira[1,3], L. Costa[1], R. M. Ferreira[1,2]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal; [2]Department of Medicine, Faculty of Medicine, University of Porto, Porto, Portugal; [3]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Background
Fibrous dysplasia of bone (FD) is a rare skeletal disorder caused by defective osteoblastic differentiation, being associated with bone pain, deformity, and fractures. Treatment options remain limited. Although bisphosphonates, particularly zoledronic acid (ZA) and pamidronate, have been reported to improve pain, their effects on disease progression are unclear.
Case Report
We report the case of a 44-year-old woman with craniofacial polyostotic FD since the age of 6. Medical history included controlled hyperthyroidism, menarche at 13 years, and menopause at 41 years. Since 2023, the patient presented progressive right mandibular enlargement and worsening pain refractory to analgesic therapy. No visual, auditory or neurological deficits were observed. Serial craniofacial CT scans (2019-2024) showed extensive craniofacial FD with a mixed radiological pattern, combining ground-glass hyperdense areas and lytic/cystic lesions, associated with marked bone expansion. Predominant involvement included the right hemimandible (with progressive cystic expansion, cortical thinning, and focal discontinuity extending to the condyle), left temporal bone and mastoid, sphenoid body and wings, occipital bone, and bilateral frontal bones. Bone scintigraphy showed increased uptake limited to craniofacial bones. Laboratory evaluation revealed markedly elevated bone turnover markers (bone-specific alkaline phosphatase, C- and N-terminal telopeptide of type I collagen, and osteocalcin), with normal calcium, phosphate, parathyroid hormone, thyroid stimulating hormone, thyroxine, vitamin D, prolactin, insulin-like growth factor 1, and growth hormone. Mandibular biopsy confirmed FD, with negative MDM2 expression and no evidence of malignancy. Densitometry showed osteoporosis (OP) at the distal radius (T-score -5.3) and femoral neck (T-score -2.8). ZA was initiated in April 2025, resulting in significant pain improvement and radiological disease stability.
Conclusion
This case illustrates severe craniofacial polyostotic FD and OP. ZA was associated with significant pain improvement, and radiological stabilization, supporting its use in symptomatic FD particularly with concomitant OP, although long-term effects on disease progression require further study.

P327

MEDICATION-RELATED OSTEONECROSIS OF THE JAW AND ATYPICAL FEMUR FRACTURES ASSOCIATED WITH ANTIRESORPTIVE THERAPY IN OSTEOPOROSIS: A 10-YEAR RETROSPECTIVE ANALYSIS

B. Fernandes Esteves[1], M. Correia Natal[1], M. Oliveira[1,2], A. Bernardo[1], A. Martins[1], B. M. Fernandes[1], C. Vaz[1], G. Terroso[1], L. Costa[1], M. Bernardes[1], P. Madureira[1], S. Garcia[1], T. Rocha[1], R. M. Ferreira[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal; [2]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Background
Medication-related osteonecrosis of the jaw (MRONJ) and atypical femur fractures (AFF) are rare but serious adverse events associated with antiresorptive therapy for osteoporosis (OP). Post-event management remains controversial. We aim to describe MRONJ and AFF cases secondary to antiresorptive treatment over a 10-year period in a tertiary rheumatology center.
Methods
We conducted a retrospective observational study including all MRONJ and AFF cases diagnosed between 2014 and 2024. Sociodemographic, clinical, and therapeutic data were collected. Descriptive analysis was performed, comparisons between MRONJ and AFF groups were conducted using appropriate statistical tests. Statistical significance was set at $p<0.05$.
Results
Thirteen patients were included: 9 (69.2%) with MRONJ and 4 (30.8%) with AFF. All patients were female, with a mean age of 72.1 ± 6.6 years and a mean OP duration of 13.7 ± 5.1 years. Prior fractures were present in 53.8% of patients. Mean baseline lumbar spine BMD was 0.948±0.2g/cm² and femoral BMD was 0.796±0.8g/cm². ONJ occurred in 3 patients receiving denosumab (Dmab) and 6 receiving bisphosphonates (BPs), while all AFF cases occurred in patients receiving alendronate. AFF patients had a longer OP duration prior to the event (14.1 ± 2.9 vs. 7.9 ± 4.9 years; p=0.043) and antiresorptive exposure (8.5 (IQR 11) vs. 3 (IQR 3.1) years; p=0.011). Among MRONJ, Dmab was associated with shorter exposure time than BPs (p=0.024). All patients discontinued antiresorptive therapy; 53.9% received subsequent OP treatment: 5 (38.5%) teriparatide and 2 (15.4%) Dmab.
Conclusion
Consistent with previous reports, AFF was associated with longer antiresorptive exposure. Interestingly, in MRONJ cases, Dmab occurred after a shorter treatment period compared to BPs. Although treatment discontinuation after MRONJ or AFF remains controversial, antiresorptives were stopped in all cases. In patients with high fracture risk, subsequent OP treatment is challenging. Teriparatide appears to be the preferred option after BPs-related events and may support tissue healing; however, its use after Dmab can be associated with bone loss. Therapeutic options following teriparatide remain limited, and optimal sequential strategies are undefined.

P328

A PANORAMIC VIEW OF OSTEOARTHRITIS IN NEPAL: KNOWLEDGE, ATTITUDES, AND PRACTICES AMONG ADULTS AND SELF-MANAGEMENT STRATEGIES AMONG PATIENTS WITH KNEE OSTEOARTHRITIS

B. Ghimire[1], S. Maharjan[2], G. Mainali[3]

[1]Kathmandu University School of Medical Sciences, Dhulikhel, Nepal; [2]Grande International Hospital, Kathmandu, Nepal; [3]Makwanpur technical institutue, Makwanpur, Nepal

Introduction and objectives:
Osteoarthritis (OA) is a highly prevalent joint condition and a leading cause of pain, functional limitation, and reduced quality of life worldwide. Knee osteoarthritis is particularly disabling, contributing to long-term disability and reduced mobility. In Nepal, despite a growing OA burden, there is limited evidence on community-level knowledge, attitudes, and practices (KAP) related to OA, as well as on self-management strategies adopted by patients with knee OA. Insufficient awareness and suboptimal self-management may perpetuate disability and poor outcomes. Self-management encompasses an individual's ability to manage symptoms, treatment, and the physical and psychological consequences of living with a chronic disease and is considered a first-line approach in knee OA management. Misconceptions regarding OA causes, risk factors, and management persist due to inadequate public understanding. KAP surveys help identify these gaps, informing interventions to promote healthy behaviors and improve disease management. To our knowledge, no study in Nepal has evaluated community-level OA knowledge and patient self-management strategies. This study aimed to assess KAP regarding osteoarthritis among adults in the Dhulikhel community and explore self-management strategies among patients with knee OA attending Dhulikhel Hospital.
Methods: Two cross-sectional surveys were conducted. Both questionnaires were developed from existing literature, validated by an expert committee for face and content validity, and pretested among 10% of participants. The first survey included 385 community adults who completed a self-administered questionnaire on KAP on OA. Knowledge was scored out of ten, with one point for each correct answer. Attitude (five items) and practice (two items) were rated on five-point Likert scales. Participants were categorized into quintiles: very poor (0–20%), poor (21–40%), satisfactory (41–60%), good (61–80%), and very good (81–100%). Use of preventive strategies, including exercise and weight management, was recorded. The second survey included 101 patients with knee OA, assessed for self-management strategies using a 27-item self-administered questionnaire. Items were rated on a five-point Likert scale from always to never. Reported strategies were compared with guideline-recommended approaches and the five most commonly used strategies were identified.
Results: Among community adults, most had satisfactory knowledge (n = 216, 56%), good attitudes (n = 233, 60%), and satisfactory practices (n = 150, 39%). Fewer than half engaged in recommended preventive strategies: exercise (n = 161, 42%) and weight management (n = 177, 46%). Among patients, adherence to guideline-recommended strategies was low: exercise (n = 20, 20%), weight reduction (n = 4, 4%), and topical agents (n = 37, 37%). The top five management strategies were massage (49%), thermal therapy (45%), prayer (40%), topical agents (37%), and prescribed medication (35%).
Conclusion: Knowledge of osteoarthritis in the community was only satisfactory, and preventive practices were limited. Patients favored passive management over guideline-recommended strategies. These findings highlight the urgent need for targeted education and policy interventions to promote evidence-based self-management, informing national strategies for osteoarthritis prevention and management in Nepal.
Key words: Osteoarthritis, Knowledge, Attitude, Practice, Self-management

P329

IMPACT OF THERAPEUTIC PATIENT EDUCATION ON INTERNALIZED STIGMA IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. L. Rouached[1], B. H. M. Ben Hriz[1], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], A. L. Abdelmoula[1], M. N. Mathlouthi[2]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Introduction : Rheumatoid arthritis (RA) is a chronic inflammatory disease, characterized by a progressive impairment of functional abilities and major psychosocial consequences. Among these, internalized stigma has emerged as a social phenomenon that may negatively affect patients' self-esteem and quality of life. Therapeutic patient education (TPE) aims to enhance patients' understanding of the disease and promote self-management.

Objective : To determine the impact of therapeutic patient education on internalized stigma among patients with RA.

Methods : We conducted a 10-month prospective study in patients with RA, diagnosed according to the 2010 ACR/EULAR criteria. At baseline (T0), sociodemographic characteristics and RA-related clinical parameters were collected. Internalized stigma was assessed using the Internalised Stigma of Mental Illness–Rheumatoid Arthritis scale (ISMI-RA). All patients attended a therapeutic patient education (TPE) session aimed at improving disease-related knowledge. A follow-up assessment of internalized stigma was performed one month later (T1) using the same scale.

Results : We included 80 patients. The mean age was 61.1 ± 8.6 years, with a male-to-female ratio of 0.11. Fifty-nine patients (73.8%) were unemployed. The majority (41.3%) were illiterate. Thirty-nine patients (49%) had a middle socioeconomic status. The mean age at RA diagnosis was 42.2 ± 14.5 years. The median disease duration was 20 years [23.25–29]. The mean disease activity score (DAS28-CRP) was 4.64 ± 1.27. RA was erosive in 96.3% of cases. The median HAQ was 1.2 [1–1.95]. At baseline, internalized stigma was severe in 61.3% of patients, with a mean ISMI-RA score of 3.05 ± 0.79. Regarding ISMI-RA subscales, Alienation was the most affected dimension. It was severe in 70% of patients, with a mean score of 3.38 ± 0.75. The "Stigma Resistance" subscale was minimal in 46.3% of patients, with a mean score of 2.16 ± 0.63. After the TPE program, the mean ISMI-RA score significantly decreased to 2.22 ± 0.52 ($p<0.001$). The proportion of patients with severe internalized stigma dropped to 2.5%, in favor of minimal and mild forms. All mean subscale scores of the ISMI-RA significantly decreased ($p<0.001$), except for the "Stigma Resistance" subscale, whose mean score significantly increased to 3.22 ± 0.42 ($p<0.001$). The variation in ISMI-RA score after the TPE was significantly influenced by

socioeconomic status (p=0.015), CRP level (p=0.047), rheumatoid factor positivity and serum titer (p=0.018 and p=0.02), as well as the presence of a total knee replacement (p=0.018).

Conclusion : These findings support the integration of TPE programs to reduce internalized stigma and enhance psychosocial well-being, while highlighting the need for further studies to confirm and expand on these effects.

P330

ASSESSMENT OF HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN KAZAKHSTAN

M. Bizhanova[1], S. Issayeva[1], E. Aseeva[2], B. Issayeva[1]

[1]Asfendiyarov Kazakh National Medical University, Almaty, Kazakhstan; [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russia

Objectives: To assess clinical features and health-related quality of life in systemic lupus erythematosus.
Methods: The study included 187 patients over the age of 18 with a diagnosis of SLE, predominantly women (95.2%), of young age (33.85 ± 10.58 years). SF-36 and LupusQol were used to assess HRQoL, with the questionnaires completed by 102 patients in Russian and 85 in Kazakh.
Results: The racial background was Caucasian - 8.3%, Asians - 91.7%, including 83.2% of Kazakh nationality. Duration of the disease at the time of inclusion in the study - 5 (2;9) years, time from the appearance of the first signs of SLE to verification of the diagnosis - 4.5 (3.0;12) years. One third of patients were diagnosed with SLE at the debut, in 63% of patients skin, neurological and other rheumatic diseases were diagnosed. Half of the patients (47%) had high disease activity (17.64 ± 8.80), with a mean level of irreversible organ damage of 59.8%. Clinical manifestations of SLE:skin involvement (75.5%), joints (79.4%), mucosal lesions (46.1%), non-scarring alopecia (75.5%), neuropsychiatric disorders (49%), hematological (54.9%), and immunological changes (100%). HRQoL assessment using the Russian version of the questionnaires revealed a significant decline across all scales, particularly on the "Emotional Health" scale -23 [19.00; 26.50]) (LupusQol) and "Role-Emotional Functioning" -33.30 [0.00; 100.00]) and "Role-Physical Functioning"-25.00 [0.00; 100.00] scales (SF-36). The analysis of questionnaires in the Kazakh version also revealed a decrease in scores on all scales, a significant decrease on the scales of "Pain" (38.32 [33.30; 55.00] and "Burden to others" - 35.32 [30.30; 45.00] (LupusQol). Patients showed significant fatigue according to LupusQol - 59.40 [42.19; 81.25] and a significant decrease on the scale of "Vitality" - 50.00 [35.00; 61.25] (SF-36). Lower disease activity improved LupusQoL scores; greater damage worsened quality.
Conclusion: HRQoL was impaired in systemic lupus erythematosus and worsened with higher disease activity and organ damage.

P331

THE ADDED VALUE OF TRABECULAR BONE SCORE (TBS) IN EVALUATING FRACTURE RISK AMONG POLISH WOMEN

B. Jaszczyk[1], A. Nowakowska - Płaza[2], B. Stypińska[1], I. Sudoł-Szopińska[1], P. Głuszko[3], R. Olszewski[1]

[1]National Institute of Geriatrics, Rheumatology and Rehabilitation, Warszawa, Poland; [2]Military Medical Institute - National Research Institute, Warszawa, Poland; [3]Multidisciplinary Osteoporosis Forum, Warszawa, Poland

Introduction
To evaluate the trabecular bone score (TBS) from lumbar spine (L1–L4) dual-energy X-ray absorptiometry (DXA) scans in Polish women aged 40–76 with and without osteoporotic fractures. The relationship between TBS, fracture risk (FRAX and FRAX adjusted TBS), and bone mineral density (BMD) at the lumbar spine, femoral neck, and total hip was investigated. No studies have been conducted in the Polish population so far to confirm the effectiveness of TBS in assessing fracture risk.
Objective
This study aimed to evaluate TBS L1-L4 in Polish women and to correlate TBS values (TBS BMD and TBS T-score) and BMD at the L1-L4 neck and total hip with fracture risk
Patients and methods
933 Polish women aged 40-76 years were included into the study. DXA scans of the proximal femur and lumbar spine were performed. Subjects with scan artifacts or extreme BMI were excluded. TBS was assessed via TBS Medimaps software; values ≤ 1.23, 1.23–1.31, and ≥ 1,31 indicated deteriorated, partially deteriorated, and normal bone microarchitecture, respectively. Patients were divided into two groups: those with low-energy fractures (n = 173) and without fractures (n = 760). The risk of fracture was assessed using the Polish version of the FRAX calculator and FRAX adjusted for TBS.
Results
TBS correlated negatively with age (r ≈ -0.36) and BMI (r ≈ -0.14). TBS and TBS T-scores were significantly lower in the fracture group ($p < 0.001$). The prevalence of osteoporotic fractures was highest in the low TBS group (28.8%) and significantly lower in the intermediate (13.0%) and high (11.9%) categories ($\chi^2=24.0$, $p<0.001$). In logistic regression, low TBS was associated with a more than threefold higher risk of fracture compared to high TBS (OR=3.0; 95% CI: 1.84–4.98; $p<0.001$). TBS models showed lower AIC and higher AUC compared with DXA alone. The addition of TBS to DXA-based models improved model fit and discrimination, with TBS remaining a significant predictor in multivariable models. In subgroups with osteopenia or osteoporosis, TBS retained statistical significance.
Conclusions
The results of our study highlight the importance of incorporating TBS into the routine clinical evaluation of bone status among Polish women. TBS provides complementary information to BMD and improves fracture risk assessment when integrated with the FRAX calculator.Routine assessment of TBS may improve clinical management of osteoporosis.

P332

REDUCING PAIN AND IMPROVING FUNCTIONAL ABILITY AFTER APPLICATION OF RADIAL EXTRACORPOREAL SHOCK WAVE THERAPY IN PATIENTS WITH KNEE OSTEOARTHRITIS

B. K. Kalchovska[1], M. G. Gocevska[1], V. K. Koevska[1], B. M. Mitrevska[1], C. G. Gerakaroska-Savevska[1], D. G. Gecevska[1], A. K. Krsetska[1], E. D. Nikolik-Dimitrova[1], M. M. Manoleva[1], M. B. Bojadzieva[2]

[1]PHI UC for Physical Medicine and Rehabilitation, Skopje, Medical Faculty, "Ss. Ciryl and Methodius" University, Skopje, North Macedonia, Skopje, North Macedonia; [2]PHI UC of Rheumatology, Skopje, Medical Faculty, "Ss. Ciryl and Methodius" University, Skopje, North Macedonia, Skopje, North Macedonia

Objective: Knee osteoarthritis is a common musculoskeletal disorder that leads to pain and reduced functional ability. of the patients. Radial extracorporeal shockwave therapy (RECTUB) has been proposed as a safe, non-invasive, alternative conservative treatment for osteoarthritis of the knee.

Material and methods: The study represents prospective, monocentric, interventional, non-randomized clinical study of 40 RECTUB treated patients (totalling 5 weekly sessions with 5-minute application of 2000 impulses, 2 Bar intensity, 10 Hz frequency at painful knee points) and kinesitherapy. The patients' progress was monitored on the Numeric scale of pain and the WOMAC Index. The clinical findings were evaluated before the treatment started; immediately after its completion and 3 and 6 months afterwards.

Results: Statistically significant differences were found of the total WOMAC index and its three subscales at the end of the first, second and third control. The three subscale WOMAC index median was 9, 4, 2, and 2 respectively for subscale 1; 3 and 0 for subscale 2; 34.5, 12.5, 7.5 and 8 at baseline and the three follow-up examinations and subscale 3 respectively, at the beginning and the three follow-up examinations. Regarding the Numeric Scale of Pain scored a mean of 7, 4, 2, and 2, respectively, before treatment and at the three follow-up examinations after treatment. It was found that patients had reduced pain intensity was maintained even for 6 months after the applied physical treatment.

Conclusions: RECTUB is becoming a treatment option for knee osteoarthritis with insufficient scientific papers published on its effectiveness. In a systematic review and meta-analysis of 14 randomized studies published in Spain, RECTUB was found to contribute to greater reduction of pain and improvement of WOMAC index values in a short time. Regarding the effectiveness of RECTUB treatment in patients with knee osteoarthritis for 6 months, as per Shieh meta-analysis measuring pain intensity according to the VAS scale and the degree of functionality according to the WOMAC index, it was found that pain reduction and improvement of the patients' functionality were maintained up to 6 months after the application of this physical modality.

P333

THE RELATIONSHIP BETWEEN DIGITAL HEALTH LITERACY LEVELS AND PAIN AND PSYCHOSOCIAL FACTORS IN PATIENTS WITH FIBROMYALGIA: PİLOT STUDY

E. Oney[1], B. Korkut[1], M. M. Elbeyli[1], F. M. Akpinar[1], E. Tarihci Cakmak[1], S. Arman[1]

[1]Department of Physical Medicine and Rehabilitation, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Objective: Fibromyalgia syndrome (FMS) is a chronic pain syndrome characterized by widespread pain that impairs functionality and quality of life, and is closely associated with psychosocial factors such as anxiety and depression. With the increasing use of digital health resources in chronic pain management, digital health literacy (DHL) has become a significant factor. This study aimed to examine the relationship between DHL levels and pain and psychosocial symptom burden in FMS patients.

Materials and Methods: This pilot study included 66 adults with FMS (63 women, 3 men). Demographic and sociocultural characteristics, perceptions of data safety, and access to health-related information sources were recorded. DHL was assessed using the 8-item eHealth Literacy Scale (eHEALS), and participants were classified as having low or high DHL based on a cutoff score of ≥26. Pain intensity and psychosocial factors were assessed using the Numeric Pain Rating Scale (NPRS), Revised Fibromyalgia Impact Questionnaire (FIQR), Hospital Anxiety and Depression Scale, Short Illness Perception Questionnaire, Perceived Stress Scale-10, Pain Catastrophizing Scale, and Tampa Kinesiophobia Scale.

Results: No significant differences were observed between DHL groups in terms of gender, marital status, education level, occupation, or income ($p > 0.05$). Individuals with higher DHL were significantly more likely to use Google and YouTube for health-related information searches ($p = 0.014$ and $p = 0.044$). Clinically, the low DHL group showed significantly higher FIQR scores ($p = 0.047$), night-time pain severity ($p = 0.009$), and perceived stress levels ($p = 0.006$) compared to the high literacy group. DHL showed a weak but statistically significant negative correlation with perceived stress level ($r = -0.326$; $p = 0.008$). No significant association was observed with other pain or psychosocial variables.

Conclusion: In FMS patients, low DHL is associated with increased disease burden, more severe night-time pain, and higher perceived stress levels. These findings demonstrate that DHL is a clinically significant factor associated with symptom severity and higher perceived stress levels with potential indirect implications for coping mechanisms and may be considered in patient education and self-management strategies.

P334

EVALUATION OF CHATBOT-GENERATED TREATMENT RECOMMENDATIONS AND RESPONSES TO PATIENT QUESTIONS IN KNEE OSTEOARTHRITIS: PRELIMINARY RESULTS

B. Korkut[1], E. Oney[1], E. Tarihci Cakmak[1], F. M. Akpinar[1], S. Arman[1]

[1]Istanbul University Istanbul Faculty of Medicine Department of Physical Medicine and Rehabilitation, Istanbul, Türkiye

Objective: Chatbots using large language models are used in clinical decision-making processes. This study aims to evaluate the concordance of knee osteoarthritis (OA) recommendations generated by chatbots with the ESCEO guideline, and the characteristics of responses to patients' questions.

Material and Methods: Clinical data from twenty knee OA cases presenting with knee pain to the physical medicine and rehabilitation (PMR) outpatient clinic in December 2025 were recorded, including medical history, physical examination, and radiographic findings. Data were entered into ChatGPT-5.2 and Gemini-3 using the same standardized prompt for all cases, with each query was conducted in isolated and anonymous sessions with prior conversation history cleared. Treatment recommendations generated by the models and responses to a single patient-initiated treatment-related question were recorded. Recommendations were independently classified as concordant, partially concordant, or discordant according to the ESCEO 2019 guideline by two blinded PMR specialist researchers. Readability of responses to questions was assessed using Flesch Reading Ease (FRE) and Flesch–Kincaid Grade Level (FKGL); understandability (PEMAT-U) and actionability (PEMAT-A) were evaluated using PEMAT; and empathic characteristics of the responses were assessed by a five-point Likert scale. Inter-rater agreement was analyzed for all assessments.

Results: Recommendations were guideline-concordant in 75% of cases for ChatGPT and 65% for Gemini, with 15% discordant for both models ($p = 0.746$). The mean FRE scores were 54.78 for ChatGPT and 52.73 for Gemini ($p = 0.346$), and the mean FKGL scores were 10.77 and 11.66, respectively ($p = 0.074$). PEMAT-U scores were higher for Gemini ($p = 0.022$), whereas PEMAT-A scores did not differ significantly ($p = 0.102$). Empathy scores were significantly higher for Gemini (4.75 vs 4.35; $p = 0.046$). Inter-rater agreement was good to excellent across all assessments (κ/ICC > 0.80; $p < 0.001$).

Conclusion: Chatbots provide largely ESCEO-concordant recommendations for knee OA; however, using them alone may pose risks to clinical safety. Chatbot responses are generally empathetic, understandable, and actionable, but simplification of language is needed to enhance readability and accessibility.

P335

OSTEOPOROSIS AWARENESS AND KNOWLEDGE GAPS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

B. Kucukhuseyin[1], S. Tuzun[1]

[1]Istanbul University - Cerrahpaşa School of Medicine, Department of PM&R, Istanbul, Türkiye

Objective

Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease characterized not only by progressive spinal ankylosis but also by profound alterations in bone metabolism. AS is associated with accelerated bone loss, impaired bone quality, and a markedly increased risk of fragility fractures. However, osteoporosis remains underdiagnosed in this population, partly due to insufficient patient awareness. The aim of this study is to evaluate osteoporosis awareness and knowledge levels in patients with AS and to explore their associations with demographic and clinical characteristics.

Material and Methods

This cross-sectional study includes 91 patients aged ≥18 years who fulfilled the ASAS 2009 criteria for ankylosing spondylitis. After obtaining informed consent, demographic characteristics, educational status, clinical features, comorbidities, and treatment history were recorded. Osteoporosis awareness was assessed using the Osteoporosis Awareness Scale (OAS), and osteoporosis-related knowledge was evaluated using the Revised Osteoporosis Knowledge Test (R-OKT), both validated in Turkish. Questionnaires were administered either face-to-face or via an online platform. Statistical analyses were performed using SPSS v29.0, with $p<0.05$ considered statistically significant.

Results

Among 91 patients, the mean total R-OKT score was 13.84 out of 32, indicating a low level of osteoporosis-related knowledge. The mean total OAS score was 64.98 out of 124, reflecting insufficient osteoporosis awareness. Subgroup analysis of R-OKT revealed that the 'nutrition' was the least recognized domain (9.59/26; 36.88%).

Subgroup analysis of OAS revealed that 'risk factors' demonstrated the lowest score (8.41/20, 42.05%). OAS scores were significantly higher in women compared with men ($p=0.007$). Patients with higher education levels demonstrated significantly greater awareness than those with primary education ($p=0.010$).

Conclusion

Despite their high fracture risk, patients with ankylosing spondylitis demonstrate low osteoporosis awareness and knowledge. The influence of sociodemographic factors highlights the need for targeted, structured educational interventions to improve early recognition and prevention of osteoporotic fractures in this vulnerable population.

P336

CASCADE VERTEBRAL FRACTURES IN ERDHEIM-CHESTER DISEASE: A RARE MANIFESTATION OF QUALITATIVE BONE FRAGILITY

B. Kuyukunu[1], F. Martins[2]

[1]Department of Rheumatology, Ibn Rochd University Hospital, Casablanca, Morocco, Casablanca, Morocco; [2]Department of Rheumatology,Rodez Hospital, Rodez, France

Objective Erdheim-Chester disease (ECD) is a rare non-Langerhans histiocytosis with frequent bone involvement, but spontaneous vertebral fractures are exceptional. We report a case of cascade vertebral fractures in ECD despite normal bone mineral density, highlighting qualitative bone fragility.

Methods A case of confirmed ECD presenting with cascade thoracolumbar fractures is described. Bone status was assessed by serial CT scans, 18F-FDG PET-CT, dual-energy X-ray absorptiometry (DXA), and comprehensive laboratory workup including bone turnover markers, endocrine and inflammatory parameters. Informed consent was obtained.

Case report A 70-year-old man followed for ECD presented with spontaneous thoracolumbar pain without trauma. June 2025 CT showed multiple sequential compression fractures (T7, T9-T12, L1-L3, minimal L4), evolving from an isolated T7 fracture two months earlier . DXA revealed normal T-scores (femoral neck +0.1, lumbar spine +0.1) with mild distal radius osteopenia (-1.2). 18F-FDG PET-CT confirmed persistent diffuse spinal medullary hypermetabolism consistent with active ECD infiltration, whereas extra-osseous lesions (renal, peritoneal, splenic) regressed. No osteoporosis, corticosteroid exposure, or secondary endocrine/rheumatologic cause was identified. Biological and endocrine workup was normal except for mild anemia (Hb 10.6 g/dL), lymphopenia (740/mm³), CRP 31 mg/L, alkaline phosphatase 158 IU/L. Management included lumbar bracing, opioid analgesia, and a single 5 mg zoledronic acid infusion. At three-month follow-up, complete pain resolution allowed discontinuation of brace and opioids, with full functional recovery.

Conclusion Cascade spontaneous vertebral fractures represent a rare but severe complication of ECD due to qualitative bone fragility from histiocytic medullary infiltration despite preserved bone density. Orthopedic stabilization combined with zoledronic acid provided rapid and sustained improvement. ECD should be considered in the differential diagnosis of unexplained vertebral fractures.

P337

TISSUE-SPECIFIC RESPONSES OF 3D-CULTURED HUMAN MESENCHYMAL STEM CELLS (MSCS) IN OSTEOGENIC COMMITMENT INVOLVES SIMULTANEOUSLY RAPID RESPONSES IN TRANSCRIPTIONAL AND MITOCHONDRIAL PROCESSES

M.-L. Yen[1], L.-T. Wang[2], H. H. Wang[1], C. Y. Liao[3], P. J. Hsu[3], B. L. Yen[3]

[1]National Taiwan University, Taipei, Taiwan; [2]Taipei Medical University, Taipei, Taiwan; [3]National Health Research Institutes, Zhunan, Taiwan

Objective: Mesenchymal stem cells (MSCs) are progenitors of osteoblasts, a critical cell type in osteoporosis (OP), and among the most easily accessible cell source for bone tissue engineering. While the transcriptional and molecular program for osteogenic commitment is well known, the impact of metabolic—including mitochondrial processes—and physical alterations such as 3-dimensional (3D) *in vitro* culture on this process is still being unraveled.

Materials & Methods: Whole transcriptome analyses was performed on standard 2D- and 3D-cultured human MSCs from different sources, with functional validation performed in terms mitochondrial activity assays and osteogenic differentiation.

Results: Whole transcriptomic analyses revealed significant enrichment of cell adhesion and mitochondria-related pathways in two sources of MSCs after 3D culture, with functional validation demonstrating larger spheroid formation, augmentation of mitochondrial activity, as well as upregulation of key osteogenic markers RUNX2 and osteoprotegerin in 3D-cultured source-specific MSCs. The rapidity of transcriptional responses within hours was surprising, and directly implicated mitochondrial processes. 3D culture further enhanced osteogenic commitment as evidenced by single-cell RNA sequencing, which demonstrated enrichment of cell clusters with high expression of mitochondrial- and osteogenesis-related genes. Functional validation was performed in which inhibition of mitochondrial function suppressed osteogenic differentiation in short-term 3D-cultured MSCs.

Conclusion: 3D culture rapidly promote the transcriptional program of osteogenesis as well as mitochondrial processes in human MSCs. These findings implicate the translational value of understanding how modulation of *in vitro* processes can significantly impact stem cell commitment.

P338

EFFICACY CONSISTENCY OF SB16 TO REFERENCE DENOSUMAB IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS: SUBGROUP ANALYSIS BY DEMOGRAPHIC AND BASELINE DISEASE CHARACTERISTICS OF A RANDOMIZED PHASE III CLINICAL TRIAL

R. Eastell[1], Y. Rhee[2], N. Guañabens[3], P. Hadji[4], J. Han[5], J. Yeom[5], S. Ahn[5], D. Youn[5], B. Langdahl[6]

[1]Division of Clinical Medicine, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom; [2]Department of Internal Medicine, Institute of Endocrine Research, Yonsei University College of Medicine, Seoul, South Korea; [3]Servicio de Reumatología, Hospital Clínic, IDIBAPS, Universitat de Barcelona, Barcelona, Spain; [4]Frankfurt Center for Bone Health and Endocrinology, Frankfurt am Main, Germany; [5]Samsung Bioepis Co., Ltd., Incheon, South Korea; [6]Department of Endocrinology, Aarhus University Hospital and Department of Clinical Medicine, Aarhus University, Aarhus, Denmark

Objective:
A randomized, double-blind, multicenter phase III study (NCT04664959) in postmenopausal osteoporosis confirmed clinical similarity of SB16 biosimilar denosumab to reference denosumab (DEN).[1] Since clinical features may influence responses to DEN, we conducted exploratory analysis on comparing efficacy between SB16 and DEN across various patient subgroups.
Material and Methods:
456 patients were randomized to receive either SB16 (n=225) or DEN (n=231) and included in the full analysis set.[1] Patients were analyzed to compare the treatment difference in 90% confidence intervals (CIs) (and 95% CIs) by demographics and baseline disease characteristics, including age, body mass index (BMI), prevalent vertebral fracture status, prior oral bisphosphonate (BP) use and smoking status.[1] Percent changes from baseline (%CFB) in lumbar spine (LS), total hip (TH), and femoral neck (FN) BMD were assessed across these subgroups at month 12. Post-hoc subgroup analysis compared SB16 to DEN using an ANCOVA with the baseline BMD as a covariate.
Results:
At month 12, consistent treatment effects were observed between SB16 and DEN of adjusted least square mean (LSM) within subgroups for %CFB in LS BMD. The treatment difference (SB16-DEN) in the 90% CIs were as follows: age < 70 years, 0.33 [-0.25, 091]; age ≥ 70, 0.78 [-0.31, 1.87]; BMI < 25 kg/m^2, 0.51 [-0.29, 1.30]; BMI ≥ 25 kg/m^2, 0.07 [-0.82, 0.96]; patients with prevalent vertebral fracture, 0.42 [-0.43, 1.27]; patients without prevalent vertebral fracture, 0.32 [-0.50, 1.14]; patients with prior oral BP uses, 1.07 [-0.65, 2.79]; patients without prior oral BP uses, 0.23 [-0.40, 0.85]; patients who smoke, -1.01[-2.97, 0.04]; and patients who do not smoke, 0.50 [-0.11, 1.11]. The subgroup analysis of the treatment differences in TH BMD and FN BMD at 12 months were also consistent with the overall analyses results.
Conclusion:
SB16 had shown overall consistent efficacy in LS BMD, TH BMD, and FN BMD to DEN by month 12 within subgroups by demographic and baseline disease characteristics of its Phase 3 study which further supports biosimilarity of SB16 to DEN.

P339

IMPACT OF ACUTE FRACTURE ON OPPORTUNISTIC BONE DENSITY MEASUREMENT FROM WRIST X-RAYS USING IBEX BH

R. Meertens[1], F. Manning[1], P. Lewis[2], T. Bean[2], N. Ashley[2], D. Joyce[3], B. Lopez[3]

[1]University of Exeter, Exeter, United Kingdom; [2]Royal Cornwall Hospital Trust, Truro, United Kingdom; [3]Ibex Innovations Limited, Sedgefield, United Kingdom

Objective: To compare areal Bone Mineral Density (aBMD) at the Ultra-Distal (UD) and Third Distal (TD) regions of interest (ROIs) in patients with acute UD fractures versus a non-fracture group using IBEX BH software on opportunistic wrist X-rays.
Material and Methods: A total of 167 wrist X-rays were analysed (mean age 69 years, 70% female), including 57 participants with an acute UD region fracture and a subset of 48 X-rays containing both measurable TD and UD regions. Unlike typical post-healing assessments, this study utilised images taken immediately post-fracture and prior to healing. aBMD values and T-scores were calculated using IBEX BH and compared between groups.
Results: The fracture group demonstrated a significantly higher aBMD in the UD region compared to the non-fracture group ($p<0.05$), with a mean T-score difference of 0.52. In contrast, the fracture group showed significantly lower aBMD in the TD region ($p<0.05$), with a mean T-score difference of -1.16. This divergence indicates that acute fracture may inflate aBMD readings within the fractured UD region compared with a pre-fracture assessment, masking the lower density observed in the adjacent TD region.
Conclusion: Caution is required when interpreting aBMD in regions with acute fractures, as density may be overestimated in the fractured ROI. Significant discrepancies between UD and TD T-scores should be anticipated in acute trauma cases, suggesting that adjacent non-fractured regions may provide a more reliable assessment of underlying bone health in this context.

P340

ASSOCIATION BETWEEN LIPOPROTEIN(A), VITAMIN D STATUS, AND CARDIOVASCULAR RISK ESTIMATED BY SCORE

B. Miskic[1], K. Miskic[2], V. Cosic[3]

[1]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK , Croatia; [2]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, Faculty of Dental Medicine and Health, Osijek, Croatia,, Osijek, Croatia; [3]UNIVERSITY OF JOSIP JURAJ STROSSMAYER OSIJEK, FACULTY OF DENTAL MEDICINE AND HEALTH OSIJEK, CROATIA, OSIJEK, Croatia

Background: A Short-Term Observational Study Background: Cardiovascular disease and osteoporosis share common pathophysiological mechanisms, including chronic inflammation, lipid disturbances, and endocrine dysregulation. Lipoprotein(a) [Lp(a)] is a genetically determined and independent cardiovascular risk factor, while vitamin D deficiency is highly prevalent and associated with adverse cardiovascular and skeletal outcomes. Evidence regarding their interaction within the cardiovascular–bone interface remains limited.
Objective: To investigate the association between serum Lp(a) concentrations, vitamin D status, and estimated cardiovascular risk assessed by the SCORE algorithm during a 3-month.
Methods: This observational study included 82 adult participants followed over a observation period. Serum levels of Lp(a), 25-hydroxyvitamin D [25(OH)D], lipid profile, and glucose were assessed during routine laboratory evaluations. Vitamin D status was categorized as deficiency (<50 nmol/L), insufficiency (50–75 nmol/L), or sufficiency (>75 nmol/L). Cardiovascular risk was estimated using the SCORE system. Comparisons were performed across vitamin D categories. Correlation analysis and multivariate regression models adjusted for age, sex, body mass index, and lipid parameters were applied.
Results: Vitamin D deficiency was observed in 46% of participants. Median Lp(a) concentrations were significantly higher in individuals with vitamin D deficiency compared with those with sufficient vitamin D levels (41.2 vs. 25.6 mg/dL; p = 0.02). Participants with low vitamin D status were more frequently classified into higher SCORE-estimated cardiovascular risk categories (p = 0.04). Serum 25(OH)D levels demonstrated a significant inverse correlation with Lp(a) concentrations (r = −0.31; p = 0.01). After multivariate adjustment, vitamin D deficiency remained independently associated with elevated Lp(a) levels (β = −0.29; p = 0.03) and increased SCORE-estimated cardiovascular risk (OR 1.9; 95% CI 1.02–3.6).
Conclusion: Over a 3-month observational period, vitamin D deficiency was independently associated with higher Lp(a) concentrations and increased estimated cardiovascular risk. These findings reinforce the relevance of vitamin D status as an integrative marker within the cardiovascular–bone interface.

P341

QUALITY OF LIFE AND FUNCTIONAL IMPACT OF FOOT DISEASE IN GOUT

O. Borgi[1], N. Ben Chekaya[2], B. Njah[2], M. Ghali[2], R. Grassa[2], S. Zrour[2], I. Bejia[2]

[1]Department of Physical Medicine, Haj Ali Soua Regional Hospital, Ksar Hellal, Monastir, Tunisia; [2]Department of Rheumatology, Fattouma Bourguiba Hospital, Monastir, Tunisia, Monastir, Tunisia

Background:

Gout is the most common inflammatory rheumatism. It usually presents as an acute, spontaneously resolving arthritis. The joints most frequently affected are the first metatarsophalangeal (MTP) joint, the midfoot, and the ankle. Although foot disease is common in gout, its consequences have not been well described.
Objectives:
The aim of this study was to evaluate the prevalence of foot problems in patients with gout and their functional impact and effect on quality of life.
Methods:

This was a prospective study including patients with gout diagnosed according to the 2015 ACR/EULAR criteria. Clinical characteristics of the disease were recorded. Foot posture was assessed using the Foot Posture Index (FPI). Overall pain was evaluated using the visual analogue scale (VAS), foot pain using the Foot Function Index (FFI), global disability using the Health Assessment Questionnaire (HAQ), and quality of life using the SF-12 questionnaire.
Results:

Thirty-six patients were included. The mean age was 71.1 ± 8.1 years, with a sex ratio of 2. The mean disease duration at the time of the study was 7.1 years for primary gout and 5.4 years for secondary gout. Regarding pain, the mean VAS score was 4.5, the mean global FFI score was 4.7, and the mean FFI pain domain score was 5. According to the FPI, 16.7% of patients had supinated foot deformities and 4.1% had pronated foot deformities. The mean HAQ score was 1.2, and 75% of patients presented with disability. The mean SF-12 physical component summary score was 41.3, while the mean mental component summary score was 49.9 indicating a decline in quality of life.
Conclusion:

This study provides a better understanding of foot disease in gout and its functional and quality of life impact. We emphasize the importance of foot care in order to adopt a new management approach that focuses primarily on orthotic treatment in patients with gout.

P342

CLINICAL CHARACTERISTICS AND MANAGEMENT OF ASEPTIC FEMORAL HEAD OSTEONECROSIS

B. Njah[1], F. Fhima[2], H. Hachfi[3], N. El Amri[3], D. Khalifa[3], R. Fakhfakh[3], K. Baccouche[3], E. Bouajina[3]

[1]Depatment of Rheumatology , Farhat Hached Hospital , Sousse , Tunisia, Monastir, Tunisia; [2]Department of medicine , Ibn el jazzar Hospital , Kairouan , Tunisia, Kairouan, Tunisia; [3]Department of Rheumatology , Farhat Hached Hospital , Sousse , Tunisia, Sousse, Tunisia

Introduction:
Aseptic osteonecrosis is a common condition that predominantly affects young adults. It results from necrosis of the epiphyseal bone secondary to ischemic or cytotoxic mechanisms, leading to pain and progressive functional impairment. The femoral head accounts for more than 75% of sites of aseptic osteonecrosis and may occur unilaterally, bilaterally, or in a multifocal manner, sometimes reflecting an underlying systemic condition.

Objective:
To describe the demographic, clinical, radiological, and therapeutic characteristics of aseptic osteonecrosis of the femoral head (AOFH).

Methods:
A retrospective study was conducted on 42 patients followed for AOFH in the Rheumatology Department of Farhat Hached Hospital in Sousse between 2001 and 2023. Collected data included age, sex, functional complaints, topography, risk factors, radiological stages according to the Arlet and Ficat classification, and therapeutic modalities.

Results:
The mean age of patients was 41.34 years (range: 14–72 years), with a male-to-female ratio of 1:1. AOFH was unilateral in 38.1% of cases, bilateral in 47.6%, and multifocal in 12%. Mechanical pain was the main reason for consultation (80% of cases), associated with functional impairment in 76%. AOFH was idiopathic in 38% of cases. Other etiologies, in decreasing order of frequency, included prolonged corticosteroid therapy (26.8%), dyslipidemia (9.3%), hematologic disorders (7%), chronic alcohol use (5%), hemochromatosis (2.7%), and trauma (2.3%). MRI enabled diagnosis at early stages in 20% of cases, when plain radiographs were often normal. Ficat stage IV was the most frequently observed (52%). Initial management was conservative (physical therapy, analgesics, and load reduction); however, 19.5% of patients required total hip arthroplasty.

Conclusion:
AOFH is an irreversible and potentially disabling condition, with a frequently unfavorable outcome in the absence of early management. MRI is the key investigation for early diagnosis, and radiological staging guides therapeutic decision-making. Conservative treatment is considered in early stages, whereas advanced forms warrant prosthetic surgical intervention.

P343

MUSCULOSKELETAL DISORDERS IN PIANISTS: PREVENTION IS BETTER THAN CURE

B. Njah[1], O. Ben Mrad[2], R. Grassa[1], N. Ben Chekaya[1], M. Ghali[1], S. Zrour[1], I. Bejia[1]

[1]Department of Rheumatology, Fattouma Bourguiba Hospital, Monastir, Tunisia, Monastir, Tunisia; [2]Upsat institution , Sousse , Tunsia, Sousse, Tunisia

Introduction:
Musculoskeletal disorders (MSDs) are a frequent issue among musicians, particularly pianists, whose demanding practice combines prolonged postures, repetitive movements, and significant biomechanical constraints. These factors increase the risk of pain and functional limitations. Prevention, which is essential to limit the occurrence of MSDs, remains insufficiently integrated into pianists' practice. This study aims to describe MSDs among Tunisian pianists, identify contributing factors, and emphasize the importance of improved implementation of preventive measures in this population.

Materials and Methods:
This was a descriptive study conducted among 35 actively practicing pianists in Sousse (Tunisia), aged between 18 and 60 years, with equal numbers of women and men and no prior rheumatologic history. Participants completed a questionnaire collecting sociodemographic and professional data, playing habits, pain assessment using a visual analog scale (VAS), pain management strategies, and the impact of pain on daily activities measured by the Disabilities of the Arm, Shoulder and Hand (DASH) score.

Results:
More than half of the respondents had been practicing the piano for less than 10 years (57.1%), and slightly more than one quarter practiced for more than 20 hours per week. The majority (80%) played between 3 days (28.6%) and 6 days (34.3%) per week. Most participants reported taking breaks during practice sessions, although one quarter never took breaks. Overall, 94.3% reported experiencing pain, most commonly in the lower back and shoulders (25.7% and 17%, respectively). Pain was reported at least once per week by most participants (37.1%) and was rated as moderate in intensity (VAS score 3–5). Women reported more severe upper limb pain than men, with a mean DASH score of 21.94. The mean DASH score for the entire cohort was 24.97 ± 16.57. To limit or reduce pain and MSDs, pianists tended to adopt specific postural strategies. Regarding posture, 74.3% used an adjustable stool and 37.1% preferred sitting in the middle. Slightly less than half (45.7%) reported keeping their back straight, while 82.9% flexed their elbows at approximately 90°. However, more than one third (37.1%) were unable to specify their back position. The impact of MSDs on daily activities increased with the number of practice days per week ($p = 0.011$). Most pianists reported lacking information on MSD prevention (68.6%).

Conclusion:
Pianists frequently experience pain, mainly related to the duration of practice sessions, insufficient breaks, and sometimes inadequate postures. Preventive measures remain largely neglected. The implementation of programs incorporating targeted exercises, self-rehabilitation practices, and an educational component aimed at correcting postural habits and disseminating preventive information appears essential to reduce the frequency and impact of MSDs among pianists.

P344

COMPARISON OF MCKENZIE METHOD AND MULLIGAN CONCEPT IN THE MANAGEMENT OF CHRONIC LOW BACK PAIN

I. Loubiri[1], B. Njah[2], M. Gaddour[1], M. Aloulou[3], N. El Fani[3], S. Frigui[1], S. Jemni[1]

[1]Department of Physical medicine, Sahloul Hospital , Sousse , Tunsia, Sousse, Tunisia; [2]Depatment of Rheumatology , Farhat Hached Hospital , Sousse , Tunisia, Sousse, Tunisia; [3]Department Of Physical medicine , Ibn El Jazzar Hospital , Kairouan , Tunisia, Kairouan, Tunisia

Introduction: Chronic low back pain is defined as pain lasting more than 3 months. It leads to physical and psychological deconditioning, causing disruption in both professional and personal life. Management of chronic low back pain is multidisciplinary, with physical therapy being the first-line treatment. Often, standard protocols are supplemented by one of two techniques: Mulligan Concept or McKenzie Method. This raises the question: which technique is more effective for managing chronic low back pain?

Objective: To compare the effectiveness of the McKenzie Method versus the Mulligan Concept in the rehabilitation of patients with chronic low back pain.

Materials and Methods: This experimental comparative study involved 10 patients followed at the physical medicine department. Patients were divided into two groups: Group A received a standard protocol combined with the McKenzie Method, while Group B received the standard protocol combined with the Mulligan Concept. Each group comprised five patients. The comparison between groups focused on several criteria: pain assessed by the Visual Analog Scale (VAS), functional capacity measured by the EIFEL score, spinal and pelvic flexibility (finger-to-floor distance, Schober's index, inclination, rotation), lumbar endurance (Sorensen test), and quality of life measured by the DALLAS self-questionnaire. Evaluations were performed at baseline and after 6 weeks of rehabilitation.

Results: The average age of the 10 patients (6 women, 4 men) was 41.9 years, with an average symptom duration of 1.04 years. The McKenzie group demonstrated a mean pain reduction of 3.1 on the VAS, compared to 4.25 in the Mulligan group. For mobility, McKenzie resulted in a 19 cm improvement in finger-to-floor distance and a 3.8 cm improvement in Schober's index, while Mulligan showed improvements of 15 cm and 2.5 cm, respectively. Lumbar endurance increased from 41s to 115s for McKenzie, versus 40s to 85s for Mulligan. In terms of functional capacity (EIFEL), McKenzie achieved an average gain of 51%, compared to 33% for Mulligan. Quality of life improved significantly for both groups, with a 25.33% improvement for Group A (McKenzie) and a 24.67% improvement for Group B (Mulligan).

Discussion: The results indicate that the McKenzie Method is superior, particularly in terms of spinal and pelvic flexibility, showing a more significant average gain compared to Mulligan. McKenzie also demonstrated better improvements in functional capacity (from 76% to 16%) compared to Mulligan (from 65% to 32%). Psychologically, a gain of 2 was observed for McKenzie, compared to 1.4 for Mulligan.

Conclusion: Based on the results of our study, the McKenzie Method appears to be more effective than the Mulligan Concept as an adjunctive approach in the management of chronic low back pain.

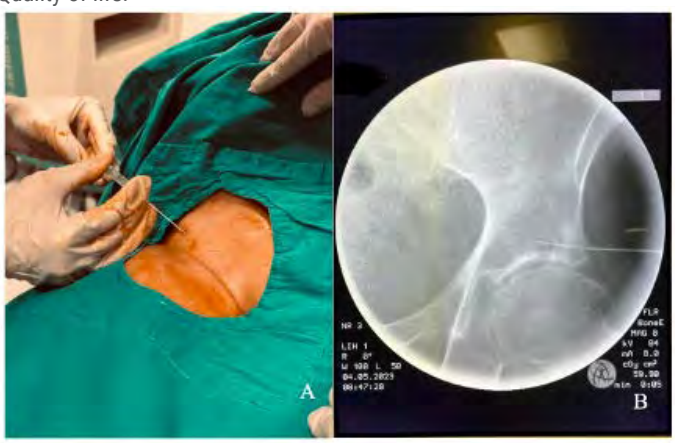
P345

PULSED RADIOFREQUENCY TREATMENT OF ARTICULAR BRANCHES OF FEMORAL AND OBTURATOR NERVES USING ULTRASOUND AND FLUOROSCOPY GUIDANCE IN MANAGEMENT OF COXARTHROSIS: A RANDOMIZED TRIAL

B. Ozlemis[1], F. Korkmaz[1]

[1]Ankara Bilkent City Hospital, Ankara, Türkiye

ABSTRACT



Objective: This study investigated the effects of pulsed radiofrequency (PRF) of articular branches of femoral and obturator nerves on pain, functional level, functional capacity, and quality of life (QOL) in patients with coxarthrosis.

Methods: Twenty-eight patients with coxarthrosis were randomized to PRF (n = 14) or nerve block (n = 14) groups. In PRF group, PRF was applied twice for 120 seconds at 42 °C to each nerve, followed by injection of 6 mg betamethasone and 1 cc 1% lidocaine under fluoroscopic and ultrasonographic guidance. Block group received the same injections without PRF. Pain (Visual Analog Scale, VAS), active and passive range of motion (ROM), Harris Hip Score (HHS), 6-Minute Walk Test (6-MWT) and SF-36 were assessed at baseline and at 2, 4, and 12 weeks.

Results: Both groups showed significant improvements in resting, movement and night VAS scores at all follow-ups ($p<0.05$). Pain relief was 92.3% in PRF group and 78.6% in block group at week 12. ROM, HHS, and 6-MWT improved in both groups ($p<0.05$), except 6-MWT in block group at week 12 was similar to baseline ($p>0.0125$). Most SF-36 domains improved in both groups ($p<0.05$), except emotional well-being in PRF group ($p>0.05$). No significant differences were found between groups ($p>0.05$).

Conclusions: Both PRF and nerve block of articular branches of femoral and obturator nerves, under fluoroscopic and ultrasonographic guidance, provide significant pain relief, improved functional level and capacity, and enhanced QoL in coxarthrosis patients unsuitable for surgery.

Keywords: Coxarthrosis, Nerve block, Pain, Pulsed Radiofrequency, Quality of life.

OSTEOPOROSIS ASSOCIATED WITH CELIAC DISEASE PRESENTING WITH SEVERE IMPAIRMENT OF QUALITY OF LIFE

B. Rexhepi-Kelmendi[1], M. Rexhepi[1]

[1]Rheumatology Clinic, University Clinical Center of Kosova, Prishtina, Kosovo, Albania

Background: Celiac disease is a chronic immune-mediated enteropathy that may present with extra-intestinal manifestations due to nutrient malabsorption. Secondary osteoporosis is a serious but often underdiagnosed complication, particularly in patients without evident gastrointestinal symptoms.

Case presentation: We report the case of a 44-year-old woman who presented with progressive diffuse bone pain, recurrent low-impact fractures, severe fatigue, and marked impairment in quality of life over a two-year period. Laboratory evaluation revealed hypocalcemia, severe vitamin D deficiency, elevated parathyroid hormone levels consistent with secondary hyperparathyroidism, and mildly increased alkaline phosphatase. Dual-energy X-ray absorptiometry demonstrated severe osteoporosis (lumbar spine T-score −3.2; femoral neck −2.9). Serological testing showed markedly elevated anti–tissue transglutaminase IgA with normal total IgA levels and positive anti-endomysial antibodies. Duodenal biopsy confirmed Marsh–Oberhuber type 3 celiac disease.

Management and outcome: The patient was treated with a strict gluten-free diet, calcium and vitamin D supplementation, and anti-resorptive therapy. Over 12 months, biochemical parameters normalized, bone density improved, and quality of life markedly recovered.

Conclusion: Osteoporosis may be the primary manifestation of celiac disease. Screening for celiac disease should be considered in patients with unexplained osteoporosis.

P347

BONE AND NUTRITIONAL BIOMARKERS ASSOCIATED WITH FRAGILITY FRACTURES INDEPENDENTLY OF BONE MINERAL DENSITY: A REAL-WORLD COHORT STUDY

B. Tartaglia[1], D. Birra[2], C. Peirce[3], O. Romano[3], M. Maione[3], R. Muscariello[1], G. Cuomo[1], V. S. Suppa[3], C. Sepe[3], P. Tirelli[1], F. Coretti[3], E. Tirri[2], V. Nuzzo[1]

[1]UOC Internal Medicine - P.O. Ospedale del Mare - Asl Napoli 1 Centro, Napoli, Italy; [2]Rheumatology Unit - P.O. Ospedale del Mare - Asl Napoli 1 Centro, Napoli, Italy; [3]UOSD Malattie Endocrine, del Ricambio e della Nutrizione - P.O. Ospedale del Mare - Asl Napoli 1 Centro, Napoli, Italy

Objectives

To evaluate clinical, biochemical and nutritional biomarkers associated with fragility fractures independently of bone mineral density (BMD) in a real-world cohort.

Materials and Methods

We conducted a cross-sectional observational study including **232 consecutive patients** referred to a tertiary outpatient bone clinic. Patients were classified into **fractured (n = 54)** and **non-fractured (n = 178)** groups based on documented history of low-energy fractures. Demographic variables, anthropometric parameters, BMD values, FRAX score, and a wide panel of biochemical markers were collected. Group comparisons were performed using independent samples t-test or non-parametric equivalents when appropriate. Statistical significance was set at $p < 0.05$.

Results

Patients with fractures showed significantly lower lumbar spine T-score compared with non-fractured patients (mean difference 0.59, $p = 0.015$). Among biochemical parameters, fractured patients had significantly lower **serum albumin** (mean difference 0.17 g/dL, $p = 0.026$) and **serum magnesium** levels (mean difference −0.11 mg/dL, $p = 0.007$). **Mean corpuscular volume (MCV)** was also significantly reduced in the fractured group (mean difference −3.35 fL, $p = 0.024$). Renal function, assessed by serum creatinine and estimated glomerular filtration rate, showed a trend toward worse values in fractured patients. No significant differences were observed for age, body mass index, vitamin D levels, calcium, parathyroid hormone, or inflammatory markers. FRAX score did not significantly differ between groups.

Conclusions

In this cohort, fragility fractures were associated not only with lower BMD but also with alterations in nutritional and metabolic biomarkers, particularly albumin, magnesium, and MCV. These findings suggest that systemic nutritional and metabolic status may contribute to fracture risk independently of BMD and traditional risk assessment tools, supporting a more comprehensive, multidimensional approach to fracture risk evaluation.

P348

ULTRASOUND-GUIDED PROLOTHERAPY IN CHRONIC ROTATOR CUFF TENDINOPATHIES

B. Zeballos[1], F. Fontg[1], M. D. Sánchez[1], F. Orient[1], C. Agudo[1]

[1]Hospital Universitari Sagrat Cor, Barcelona, Spain

Objective(s):
To assess the effects of ultrasound-guided prolotherapy on pain, function and quality of life in patients with chronic rotator cuff tendinopathies refractory to conventional treatment.
Material and Methods:
A retrospective observational study was performed in 63 patients aged 45–70 years with chronic rotator cuff tendinopathies of more than three months' duration. Patients were allocated to an intervention group (n=31), receiving two ultrasound-guided injections of 15% dextrose at weeks 0 and 4 combined with 16 rehabilitation sessions, or to a control group (n=32), receiving rehabilitation alone. Evaluations were conducted at baseline, week 4 and week 8. Outcome measures included pain assessed by the visual analogue scale (VAS), function measured by the QuickDASH questionnaire, and health-related quality of life evaluated using the EQ-5D index.
Results:
The intervention group showed a greater reduction in pain compared with controls, with VAS scores decreasing from 7.2 ± 1.1 to 2.5 ± 1.0 versus 6.9 ± 1.2 to 4.3 ± 1.1, respectively ($p<0.01$). Functional outcomes improved in both groups, with a more pronounced reduction in QuickDASH scores in the intervention group (64.1 ± 9.3 to 26.9 ± 8.4) compared with the control group (63.7 ± 8.7 to 36.9 ± 9.1), showing a favorable trend ($p=0.08$). EQ-5D index values increased from 0.49 ± 0.12 to 0.70 ± 0.10 in the intervention group and from 0.51 ± 0.11 to 0.65 ± 0.09 in the control group ($p=0.11$).
Conclusion(s):
In this cohort, ultrasound-guided prolotherapy combined with rehabilitation was associated with a greater reduction in pain and a trend toward improved functional outcomes and quality of life compared with rehabilitation alone, supporting its use as a complementary treatment option in chronic rotator cuff tendinopathies.
Acknowledgments:
The authors thank the rehabilitation team involved in patient management and follow-up.
Disclosures:

P349

IMPLEMENTATION OF A FRACTURE LIAISON SERVICE AND POST–HIP FRACTURE OSTEOPOROSIS TREATMENT RATES IN A TERTIARY HOSPITAL (2024–2025)

M. D. Sanchez Corretger[1], F. Orient Lopez[1], B. Zeballos Buscaglia[1], F. Fontg Manzano[1], C. Agudo Fernandez[1], L. Orpinell Palacio[1], A. Lozano Miñana[1], R. Garcia Lopez[1]

[1]HOSPITAL UNIVERSITARI SAGRAT COR QUIRONSALUD, BARCELONA, Spain

Objectives
To evaluate the impact of the implementation of a hospital-based fracture liaison service (FLS) on osteoporosis treatment rates after hip fracture using a standardized healthcare quality indicator.
Material and Methods
A retrospective observational study was conducted after the implementation of an FLS in 2024. Eligible patients were those aged ≥65 years discharged after hospitalization for hip fracture between January 2024 and December 2025. The primary outcome was the healthcare quality indicator IPDMAL02-T applied to hip fracture patients, defined as the percentage of eligible patients receiving active osteoporosis treatment after discharge. Active treatment included prescription or administration of osteoporosis drugs, including hospital-dispensed medication or intravenous zoledronic acid.
Results
A total of 195 patients hospitalized for hip fracture during 2024–2025 met inclusion criteria. In 2024 (n=60), 95.0% were women (mean age 86.6 years) and 5.0% were men (mean age 84.7 years). In 2025 (n=35), 88.6% were women (mean age 88.3 years) and 11.4% were men (mean age 85.0 years). After FLS implementation, 69% of patients received active osteoporosis treatment in 2024, increasing to 78% in 2025. These treatment rates exceeded the 50% benchmark established by the regional public health insurer. Most treatments were initiated within the first months after fracture.
Conclusions
The implementation of a structured hospital-based FLS was associated with a progressive increase in osteoporosis treatment rates after hip fracture, clearly surpassing the predefined healthcare system target. These findings support the effectiveness of FLS programs in secondary fracture prevention in very elderly, high-risk patients.
Disclosures
The authors declare no conflicts of interest.

ROMOSOZUMAB IN THE OLDEST OLD: REAL-WORLD PATTERNS IN FRACTURE LIASON SERVICE COHORT

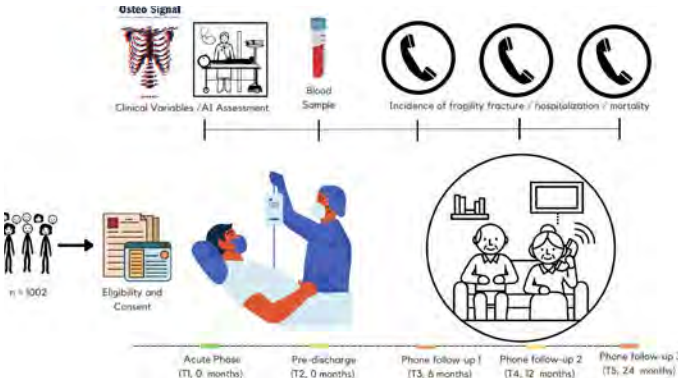
B.-A. Cedeno-Veloz[1], A.-M. Rodriguez-Garcia[2], A. Casajus[3], I. Guruceaga-Eguillor[1], V. Ruiz-Izquieta[1], I. Zazpe[3], N. Martinez-Velilla[1]

[1]Geriatric Department, Hospital Universitario de Navarra (HUN), Pamplona, Spain; [2]Navarrabiomed, IdiSNA, Pamplona, Spain; [3]Department of Neurosurgery, University Hospital of Navarre (HUN), Pamplona, Spain

Objective To characterize older adults receiving osteoporosis pharmacotherapy in routine Fracture Liaison Service care—focusing on adherence as the primary outcome—and to describe secondary functional, laboratory, and densitometric trajectories over 12 months.
Material and Methods We conducted a retrospective, single-center observational cohort study (Hospital Universitario de Navarra FLS, Spain, 2022–2024). Women at imminent fracture risk (≥1 fragility fracture within 24 months before baseline) initiating romosozumab were included. For each patient, one comparator initiating denosumab, zoledronic acid, or teriparatide was selected, matched by calendar time (same month ±3 months). Baseline variables and outcomes were assessed at 3 and 12 months. Between-group comparisons were performed using non-parametric tests (Kruskal–Wallis and Fisher–Freeman–Halton exact tests), with Holm–Bonferroni correction for pairwise comparisons.
Results Sixty-eight patients were included (n=17 per group). Baseline profiles differed significantly across treatments, reflecting clinical allocation: the romosozumab and teriparatide groups presented a higher-risk phenotype, characterized by higher baseline fracture burden and higher estimated fracture risk scores (FRAX and QFracture) compared to denosumab and zoledronic acid ($p<0.05$). During the 12-month follow-up, no significant between-group differences were observed for mortality, emergency visits, falls, new fractures, or adverse drug reactions. However, adherence distributions differed significantly at 12 months ($p<0.001$). Monthly romosozumab was associated with significantly better adherence (100%) compared to daily teriparatide (52.9%) (Holm-adjusted $p=0.016$). Functional and clinical trajectories were broadly similar across all treatment groups.
Conclusion In this very old FLS cohort, romosozumab recipients represented a higher-risk phenotype but showed broadly similar 12-month clinical trajectories compared with other therapies. Notably, monthly romosozumab demonstrated superior adherence compared to daily teriparatide in patients at very high fracture risk, supporting its utility as a preferred therapeutic option in routine geriatric practice for this vulnerable population.

P351

ARTIFICIAL INTELLIGENCE FOR OSTEOPOROSIS SCREENING AND FRACTURE RISK PREDICTION IN OLDER ADULTS: THE OSTEOFRACT-AI STUDY PROTOCOL



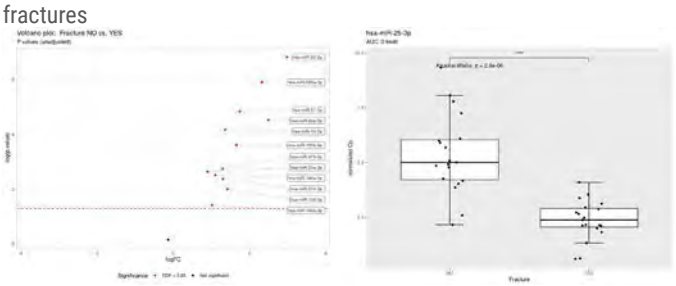
B.-A. Cedeno-Veloz[1], A.-M. Rodriguez-Garcia[2], F. Zambom-Ferraresi[2], L. Miranda-Orella[3], J.-A. Arco[2], J. Lee[4], H.-J. Bae[4], N. Martinez-Velilla[1]

[1]Geriatric Department, Hospital Universitario de Navarra (HUN), Pamplona, Spain; [2]Navarrabiomed, IdiSNA, Pamplona, Spain; [3]Radiology Department, Hospital Universitario de Navarra (HUN), Pamplona, Spain; [4]PROMEDIUS Inc, Seul, South Korea

Objective To evaluate the clinical utility and diagnostic accuracy of an Artificial Intelligence (AI) tool for opportunistic osteoporosis screening using routine chest X-rays in hospitalized older adults. Secondarily, to develop and validate a multimodal predictive nomogram for 2-year fracture risk, integrating AI-derived bone health scores, inflammatory biomarkers (immunoporosis), and comprehensive geriatric assessment variables, while addressing potential gender disparities in fracture risk stratification.
Material and Methods This is a prospective, observational, longitudinal study conducted at the Geriatric Department of the Hospital Universitario de Navarra (Spain). The study will recruit 1,002 hospitalized patients aged ≥75 years.

- **Intervention:** Routine chest X-rays will be retrospectively analyzed using a Deep Learning software (Osteo Signal®) to generate a bone health score.
- **Comparators:** AI scores will be compared against Radiofrequency Echographic Multi Spectrometry (REMS) densitometry, FRAX scores, and functional tests (PASE, 5-sit-to-stand).
- **Biomarkers:** Pre-discharge blood samples will be analyzed for osteo-inflammatory markers (NLR, PLR, SII).
- **Follow-up:** Participants will be followed for 24 months to record incident fragility fractures, mortality, and readmissions.
- **Statistics:** Area Under the Receiver Operating Characteristic Curve (AUC-ROC) will assess diagnostic performance. Multivariate Cox regression will be used to construct the predictive nomogram (OSTEOFRACT-AI).

Results We hypothesize that the AI algorithm will demonstrate high sensitivity for osteoporosis detection in this frailty-enriched cohort, comparable to REMS and superior to clinical risk factors alone. We anticipate identifying distinct "immunoporosis" profiles that correlate with higher fracture risk. The study aims to validate a cost-effective, opportunistic screening strategy that utilizes existing radiological resources to reduce the diagnosis gap, particularly in underdiagnosed older men. The final output will be a validated, sex-adjusted predictive tool for clinical use.
Conclusion The OSTEOFRACT-AI project proposes a novel, scalable approach to fracture prevention in the oldest old by repurposing routine chest X-rays through AI. If validated, this strategy could democratize access to osteoporosis screening in resource-limited



P352

THE BONE-MUSCLE CROSSTALK IN HIP FRACTURE: INSIGHTS FROM MULTI-TISSUE MIRNA PROFILING

B.-A. Cedeno-Veloz[1], M. Montes[2], C. Chenhuichen[1], N. Martinez-Velilla[1], F. Zambom-Ferraresi[3], A.-M. Rodriguez-Garcia[3]

[1]Geriatric Department, Hospital Universitario de Navarra (HUN), Pamplona, Spain; [2]Center for Applied Medical Research, University of Navarra, Pamplona, Spain; [3]Navarrabiomed, IdiSNA, Pamplona, Spain

Introduction:
Hip fracture is the ultimate consequence of osteosarcopenia, often driven by the simultaneous deterioration of bone and muscle tissue. While inflammatory biomarkers have been characterized in this population, the specific epigenetic crosstalk between bone and muscle remains unexplored. We aimed to characterize the microRNA (miRNA) signature simultaneously in bone, muscle, and serum of hip fracture patients to identify circulating biomarkers that reflect tissue-specific pathophysiology.
Methods:
We performed a cross-sectional multi-tissue analysis in 40 older adults: 20 patients with low-trauma hip fracture (HF) and 20 non-fractured controls undergoing elective hip arthroplasty (OA). Samples of trabecular bone, gluteus medius muscle, and fasting serum were collected during surgery. Expression levels of a panel of candidate miRNAs were quantified using qPCR. Data were normalized using endogenous (U6/RNU5G for tissues) or exogenous (UniSp2 for serum) controls. Statistical analysis included Kruskal-Wallis tests and ROC curve analysis.
Results:
We identified a striking molecular discordance between the musculoskeletal tissues.
Bone tissue in HF patients exhibited a massive upregulation of stress-related miRNAs, most notably miR-25-3p ($p < 0.001$, AUC=0.95) and miR-320a ($p < 0.001$), suggesting an active local remodeling or inflammatory response.
Conversely, muscle tissue showed a generalized downregulation of the same targets, including miR-25-3p ($p = 0.013$) and miR-125b-5p ($p < 0.001$), indicative of anabolic resistance or cellular senescence.
Crucially, the serum profile mirrored the muscle signature. Circulating miR-25-3p was significantly downregulated in HF patients ($p <$ **0.001,** AUC=0.94), contrasting with the high levels found in bone.
Conclusion:
Hip fracture patients present a "molecular storm" in bone (upregulation) but a "molecular silence" in muscle and serum (downregulation). These findings suggest that circulating miRNAs, particularly miR-25-3p, act as systemic reporters of muscle quality and frailty rather than indicators of local bone trauma. This highlights the potential of serum miR-25-3p as a non-invasive biomarker for sarcopenia in the context of osteoporotic fractures

THE IMPACT OF HEALTH INSURANCE COVERAGE OF CHUNA MANUAL THERAPY ON TREATMENT PATTERNS AND HEALTHCARE UTILIZATION: A NATIONWIDE CLAIMS DATA ANALYSIS (2018–2019)

J.-H. Kim[1], Y.-C. Park[2], Y.-H. Baek[2], Y. Kim[1], S.-S. Nam[2], D. Lee[1], B.-K. Seo[2]

[1]Kyung Hee University Hospital at Gangdong, Seoul, South Korea; [2]Kyung Hee University, Seoul, South Korea

Objectives
In April 2019, Chuna Manual Therapy was included in Korea's National Health Insurance system. This policy change was expected to influence treatment patterns and healthcare utilization within traditional Korean medicine; however, empirical evidence based on nationwide data remains limited.
Materials and methods
We conducted a nationwide before–after observational study using Health Insurance Review and Assessment Service (HIRA) claims data. The study population included patients treated for spinal disorders who received Chuna Manual Therapy during the 12 months following insurance coverage implementation (April 8, 2019–April 7, 2020). Healthcare utilization patterns during this period were compared with those observed in the 12 months prior to coverage. Outcomes included the number of visits per disease episode, treatment duration, use of concomitant therapies, and healthcare cost components borne by insurers and patients.
Results
Following insurance coverage, the number of patients with recorded Chuna Manual Therapy claims increased from 53,037 to 1,160,710. At the episode level, the mean number of visits per disease decreased from 5.01 ± 7.83 to 3.90 ± 5.01 ($p < 0.05$), and treatment duration was reduced from 6.02 ± 9.40 to 4.33 ± 5.97 days ($p < 0.05$). Utilization of concomitant therapies, including acupuncture, cupping, percutaneous infrared radiation therapy, and electroacupuncture, also declined significantly. In addition, both patient out-of-pocket payments and insurer expenditures per episode decreased after coverage implementation ($p < 0.05$ for all comparisons).
Conclusions
The inclusion of Chuna Manual Therapy in Korea's National Health

Insurance system was associated with notable changes in treatment patterns and healthcare utilization, including fewer visits, shorter treatment duration, and altered use of complementary therapies. These findings suggest that insurance coverage may influence care delivery structures in traditional Korean medicine. Further longitudinal and controlled studies are required to evaluate the implications of these utilization changes for clinical outcomes and healthcare efficiency.

ORIENTAL MEDICINE AS COLLABORATING TREATMENTS WITH CONVENTIONAL TREATMENTS FOR KNEE OSTEOARTHRITIS A PRISMA-COMPLIANT SYSTEMATIC REVIEW AND META-ANALYSIS

Y.-C. Park[1,2], B.-H. Goo[2], J.-H. Kim[2], B.-K. Seo[1], Y.-H. Baek[1]

[1]Kyung Hee University, Seoul, South Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, South Korea

Objectives:
We aimed to evaluate the effectiveness and safety of oriental medicine (OM) treatments as monotherapy and add-on therapy compared to conventional treatments for knee osteoarthritis and assess the quality of evidence for these results.
OM treatment included acupuncture, herbal medicine, pharmacoacupuncture, and moxibustion.
Materials and Methods:
PubMed, Embase, Cochrane, Google Scholar, 4 Korean medical databases (KoreaMed, Korean Studies Information Service System, Research Information Service System, and Oriental Medicine Advanced Searching Integrated System), and one Chinese database (China National Knowledge Infrastructure) were searched for articles published between January 1, 2000, and January 1, 2021. Randomized controlled trials (RCTs) investigating the effect of OM interventions, single or combined with conventional treatments, on knee osteoarthritis were searched. The risk of bias and quality of evidence of the included studies were evaluated using the Cochrane Collaboration's risk of bias tool and Grading of Recommendations, Assessment, Development, and Evaluation methods, respectively.
Results:
A total of 3911 relevant studies were retrieved and only 23 studies were included for systematic review. Most of the studies showed a significant effect on knee osteoarthritis. 21 studies comparing single OM treatment with conventional treatment were included in the meta-analysis. The effect size of standardized mean difference (SMD) was analyzed as a "small effect" with 0.48 (95% CI −0.80 to −0.16, Z = 2.98, P = .003). In addition, a meta-analysis of 4 studies comparing integrative treatment with conventional treatment showed a "very large effect" with 1.52 (95% CI −2.09 to −0.95, Z = 5.19, P < .001).
Conclusion:
Our results suggest that single OM treatment and integrative treatment significantly reduce pain in patients with knee osteoarthritis. However, there is a limited number of RCTs considering integrative treatment which implies more related RCT should be conducted in the future.

Keywords: acupuncture, herbal medicine, hyaluronic acid injection, knee osteoarthritis, moxibustion, NSAIDs

Abbreviations: AEs = adverse events, CI = confidence interval, HA = hyaluronic acid injections, NSAIDS = nonsteroidal antiinflammatory drugs, OA = osteoarthritis, OM = oriental medicine, RCTs = randomized controlled trials, SMD = standardized mean difference, VAS = visual analog scale.

GENERALIZABILITY OF AN OPPORTUNISTIC AI TOOL THAT IDENTIFIES PATIENTS WITH LOW BONE DENSITY USING CONVENTIONAL X-RAY ACROSS RACE AND SEX

C. A. Syme[1], M. Cicero[1,2,3], S. Narayan[1], A. Rahman[1], A. Bilbily[1,4]

[1]16 Bit Inc., Toronto, Canada; [2]True North Imaging, Toronto, Canada; [3]Department of Surgery, McMaster University, Hamilton, Canada; [4]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada

Objective: To assess the potential of a medical device software tool, Rho, which uses a locked machine learning algorithm to identify patients with low BMD from standard x-rays, to improve screening in typically underscreened patients by demonstrating its performance across sex and race.
Material and Methods: Rho analyzed x-rays of 513 patients (54% female; 26% Asian, 22% Black, 24% Hispanic, 28% White; 61% low BMD) from six US centers and classified patients as having low BMD or not. Performance was evaluated using DXA BMD (acquired within one year of the x-ray) as ground truth. Area under the receiver operating characteristic curve (AUC), sensitivity and specificity were assessed in pre-defined subgroups of sex and race.
Results: Of 513 patients, the algorithm identified 143 true positives, 14 false positives, 172 false negatives and 184 true negatives. Performance did not differ, as evidenced by overlapping confidence intervals, between females and males: AUC was 0.87 (0.83-0.90) and 0.83 (0.78-0.87), specificity was 0.94 (0.89-0.98) and 0.92 (0.88-0.96), and sensitivity was 0.48 (0.42-0.54) and 0.41 (0.34-0.49), respectively. Similar performance values were observed for each race, and did not differ between races.
Conclusions: Disparities in screening rates are documented across sex and race, but many adults, regardless of sex and race, will have a conventional x-ray performed at some point. If implemented clinically, a Rho Positive finding is intended to prompt the referring clinician to conduct a clinical fracture risk assessment and refer for DXA if appropriate. These results suggest that Rho has the potential to augment the current standard of care and help address screening disparities by flagging patients at-risk of low BMD with similar performance in different sexes and races. Most flagged patients would truly have low BMD by DXA. False negative patients would be missed, but since the device analyzes x-ray data that already exists, these patients are not subjected to additional radiation exposure. Physicians are not made aware of Rho Negative findings, thus these patients would continue to receive the current standard of care.
Disclosures: The authors are/were employees of 16 Bit. MC and AB are inventors on a patent for the underlying technology.

P356

POTENTIAL TO AUGMENT OSTEOPOROSIS CANADA GUIDELINES FOR DXA REFERRAL WITH FRAX CALCULATED USING A FEMORAL NECK ESTIMATE FROM AN OPPORTUNISTIC SCREEN OF LOW BONE DENSITY FROM STANDARD X-RAY

C. A. Syme[1], M. Cicero[1,2,3], M. Lopes[1], A. Bilbily[1,4]

[1]16 Bit Inc., Toronto, Canada; [2]True North Imaging, Toronto, Canada; [3]Department of Surgery, McMaster University, Hamilton, Canada; [4]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada

Objective: To assess the potential of a femoral neck (FN) T-Score estimate from an opportunistic screen of low bone density from standard x-rays (Rho) to improve patient referral for DXA when used as an input to FRAX.

Material and Methods: In a retrospective dataset of consecutive patients with a Rho-eligible x-ray, DXA and FRAX inputs available, we calculated FRAX MOF score with FN T-Score estimated by Rho (FRAX-Rho) and measured by DXA (FRAX-DXA). We classified patients as eligible for (i) DXA referral based on FRAX-Rho ≥ 10 or age-specific Osteoporosis Canada guidelines (OC-DXA); and (ii) pharmacotherapy based OC guidelines (OCRX). We considered the cost of DXA, risk of fracture, cost and risk reduction of pharmacotherapy, and cost of fracture to model costs of different DXA referral methods.
Results: In 1199 patients (74% female; 50-93 years of age; 56% low bone mass [lowest DXA T-Score > -2.5 and < -1] and 17% osteoporosis), had referral for DXA been based on OC-DXA or FRAX-Rho, 89/734 (12%) or 93/552 (17%; p=0.02) patients referred would qualify for OCRX, respectively. FRAX-Rho would have referred a net of 182 fewer patients, caught 4 additional eligible for OCRX, and would not have missed any eligible for OCRX, leading to cost savings > $34,000 (whereas referral based on OC-DXA incurred a cost > $9000). FRAX-Rho vs OC-DXA would refer half as many young men (<65 y) and one third as many older men (≥65 y).
Conclusions: OC guidelines are meant to improve DXA referral by considering age and risk factors, but still rely on a care provider to initiate a clinical fracture risk assessment (CFRA). Rho findings (of a patient likely having low BMD) are intended to prompt a CFRA. The current study suggests that calculating FRAX-Rho, and referring for DXA if FRAX-Rho ≥ 10, would result in DXA referrals with high diagnostic yield in a cost-effective manner. The Rho finding could be delivered to primary care providers with a weblink to the FRAX calculator, pre-filled with some patient parameters available from the Rho-analyzed x-ray (age, sex, estimated FN T-Score). As Rho findings are only available in patients who happen to have a Rho-screened x-ray, FRAX-Rho is not intended to obviate the OC guidelines, which serve all patients. Rather, when FRAX-Rho is available, it would refer fewer patients but still send all those eligible for therapy based on OC guidelines, potentially reducing DXA wait-times.
Disclosures: The authors are/were employees of 16 Bit. MC and AB are inventors on a patent for the underlying technology, assigned to 16 Bit.

STUDY OF THE ROLE OF ENVIRONMENTAL FACTORS IN PAGET'S DISEASE OF BONE IN TUNISIA

C. Abid[1], Z. Gassara[1], A. Feki[1], S. Ben Jemaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]CHU hedi chaker sfax, Sfax, Tunisia

Introduction:
The prevalence of Paget's disease of bone has been declining in recent years. Genetic and environmental factors have been reported.
We studied environmental factors in patients with Paget's disease.

Materials and methods:
We conducted a retrospective, cross-sectional, descriptive study of patients followed for Paget's disease in the rheumatology department of Hédi Chaker Hospital in Sfax over a 25-year period from 2000 to 2025. We collected sociodemographic data and data on exposure to environmental factors.

We collected data on 91 patients with Paget's disease of bone. The average age of patients at the time of diagnosis of PD was 67.75 ± 9.7 years. We observed a male predominance, with a sex ratio (M/F) of 1.39. We collected data on exposure to environmental factors in 81 patients and observed the following:
-Contact with animals in 44.21% of patients: farm animals (38.1%), dogs (35.71%), and cats (26.19%).
-Exposure to wood heating during childhood in 23.5% of patients (n=19).

-Exposure to tobacco in 47.67% of patients (n=41).

-Occupational exposure to arsenic in 13.58% of farmers (n=11).

-Exposure to heavy metals in 17% of patients working in a metallurgical factory. (n=21)

Discussion:
Regarding contact with animals, especially dogs, recent studies have suggested that CDV is present in 100% of cases of pagetic cells (1). Exposure to tobacco and wood smoke has been shown to stimulate osteoclastogenesis. Another factor studied was toxins, including arsenic acid and heavy metals, which are suspected of increasing the risk of developing PDB(2).

Conclusion:
The study of environmental factors provides insight into the pathophysiology of the decline in the prevalence of Paget's disease of bone.

EVALUATION OF CLINICAL AND BIOLOGICAL RESPONSE TO BISPHOSPHONATES IN PAGET'S DISEASE OF BONE

C. Abid[1], A. Feki[1], Z. Gassara[1], S. Ben Jemaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]CHU hedi chaker sfax, Sfax, Tunisia

Introduction:
Bisphosphonates are currently the first-line treatment for Paget's disease(PD). They have improved the control and prognosis of PD.
The response to treatment was assessed at 12 months on clinical and biological grounds.

Patients and methods:
We conducted a retrospective, cross-sectional, descriptive study of patients followed for Paget's disease of bone in the rheumatology department of Hédi Chaker Hospital in Sfax. We collected sociodemographic data and information on anti-osteoclast treatments received. We evaluated the clinical and biological response (rate of reduction in ALP) to treatment at 12 months.

Results:
We collected data from 91 patients with Paget's disease of bone. In 84.7% of cases (n=77), the diagnosis was made after the age of 60. 58.2% were men (n=53) and 41.8% were women (n=38).

We identified 84.61% of patients treated with bisphosphonates (n=77).

The bisphosphonates prescribed were: zoledronic acid in 62.34% of patients (n=48), pamidronate in 28.57% (n=22), risedronate in 6.49% (n=5), and etidronate in 2.6% (n=2).
-For zoledronic acid: A clinical and biological assessment was performed in 70.83% of patients (n=34): An improvement in pain was noted in 85.29% of patients. A normal PAL rate was noted in 88.24% of patients (n=30), while the remaining 4 patients had a reduction in PAL, with 75% (3 patients) having a reduction in PAL greater than 70%.

-For pamidronate: Clinically: An improvement in pain was observed in 90.9% of patients, and a clinical relapse was noted in 9.09%. Biologically, a biological assessment was performed in 20 patients: Biological remission was observed in 1 patient, and a reduction in PAL was observed in 19 patients, 10 of whom had a reduction in PAL of more than 70%.

-For risedronate: Clinically, clinical improvement was noted in 60% of patients. Biologically, remission was noted in 40% of patients, and a reduction in PAL was noted in 40%, i.e., 2 patients with a decrease of 39.48% and 32.28%, respectively, from the initial PAL level.

-For etidronate: Clinically, we noted an improvement in pain in both cases. Biologically, a reduction in PAL was observed of 69.92% in one patient and 55.92% in the other.

Conclusion:
Nitrogen-containing bisphosphonates, such as alendronate, pamidronate, risedronate, and zoledronic acid, are preferred because of their high affinity for bone. In our study, zoledronic acid and etidronate were clinically the most effective in relieving pain, with no clinical relapse observed. Biologically, zoledronic acid was the treatment associated with the highest remission rate.

P360

IMPACT OF CERVICOBRACHIAL NEURALGIA ON SLEEP: MOS SLEEP SCALE

C. Abid[1], H. Hachfi[2], R. I. M. Fakhfekh[2], D. Khalifa[2], K. Baccouche[2], I. Bouajina[2]

[1]CHU hedi chaker sfax, Sfax, Tunisia; [2]CHU farhat hached sousse, Sousse, Tunisia

Introduction:
Cervicobrachial neuralgia (CBN) is a common degenerative condition that causes nociceptive or neuropathic pain, which can affect patients' quality of life, particularly their sleep. The aim of our study was to assess the impact of CBN on sleep quality using the MOS Sleep Scale (Medical Outcomes Study Sleep Scale).

Patients and methods:
This was a retrospective, cross-sectional, descriptive study conducted in the rheumatology department, collecting data on patients being treated for cervicobrachial neuralgia. We collected sociodemographic data, the duration of CBN, and pain intensity assessed using the VAS pain scale. We assessed sleep quality in these patients using the MOS Sleep Scale. This is a 12-item questionnaire that explores six dimensions: Sleep quantity (considered optimal for a duration of between 7 and 8 hours, and suboptimal if less than 7 hours), number of hours of sleep, sleep disturbances, sleep adequacy, daytime sleepiness, snoring, and waking up with shortness of breath or headaches.

Each subdomain of the MOS Sleep Scale was converted into a score on a scale of 0-100, where 0 represents poor sleep quality and 100 represents good sleep quality. Depending on the domain, a high score indicates favorable sleep, or conversely, sleep disorders.

Results:
Thirty patients with cervicobrachial neuralgia were included, 90% of whom were women. The average age was 50.5 years [22–75]. In 90% of patients, CBN had been present for more than three months. The average pain intensity, as assessed by the VAS, was 6.2/10. Approximately one-quarter of patients (26.7%) reported waking up during the night.

Regarding the MOS Sleep Scale, for sleep quantity, we observed an average of 5.83 hours of sleep per night [4–8], with optimal sleep (7–8 hours) reported in 30% of patients. The sleep adequacy score was 34.7 ± 10, while the sleep disturbance score was 57.8 ± 26.8. The daytime sleepiness score was 63.6 [20–60], the score for waking up with shortness of breath or headaches was 75 [45–80], and the snoring score was 58.3 [37–95]. These results reflect a significant impairment in sleep quality in our population.

Conclusion:
Cervicobrachial neuralgia causes pain that can be chronic and intense, leading to sleep disturbance. Our study shows that CBN impacts sleep quality, contributing to an impairment in patients' quality of life.

P361

FAMILIAL RISKS OF OSTEOPOROSIS AND OSTEOPOROSIS RELATED FRACTURES IN FIRST-, SECOND- AND THIRD-DEGREE RELATIVES - A NATIONWIDE FAMILY STUDY

C. Anker-Hansen[1], M. Pirouzifard[1], J. Sundquist[1], K. Sundquist[1], B. Zöller[1]

[1]Center for Primary Health Care Research, Lund University, Malmö, Sweden

Abstract

Objective: Osteoporosis (OP) is a common degenerative disorder with complex genetic distribution. No large nationwide family study of the hereditary of OP has been published. This first nationwide study aimed to determine the familial risks of OP and OP related fractures in twins, full-siblings, half-siblings, and cousins in Sweden.

Design: The Swedish Multigeneration register was linked to the National Patient Register (NPR) to investigate the heredity of OP between 1997 and 2018. Offspring born by Swedish parents were included. The adjusted familial hazard ratios (HRs) with 95% confidence interval (CI) were determined for OP and OP fractures among twins, siblings, half-siblings, and cousins. Adjustments were made for birth year, sex, educational level, and comorbidities.

Results: Totally 6 548 562 individuals (48.77% women) were included with mean age 41 years (range 0-87 years) at end of follow up of. Totally 57 869 (0.88 %) individuals were affected with OP and 403 660 (6,16%) individuals with OP fractures. Familial adjusted HRs were increased for both OP and OP related fractures in twins, siblings, half-siblings, and cousins. The adjusted familial HR for OP were for twins HR=2.92 (95%CI 2.32-3.67), siblings HR=2.22 (95%CI 2.14-2.31), half-siblings HR=1.74 (95%CI (1.55-1.94), and cousins HR=1.81 (95%CI 1.55-2.11). The familial risk was especially high for young individuals born before 1976 with adjusted familial HR=22.88 (95%CI. 13.98-37.45).

Conclusions: Heredity is a predictor for future risk of OP and OP related fractures in the Swedish population. Heredity might be of value to identify individuals predisposed for OP for individualized targeted intervention.

P362

INDICATION CRITERIAS FOR AGN1 TO RESTORE BONE STRUCTURE IN THE PROXIMAL FEMUR

C. B. Frank[1], A. Stuetzle[2], A. Wirries[2], M. Pfefferle[1]

[1]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland; [2]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland

Background: While the need for systemic pharmacological therapy after osteoporosis related index fractures is well documented, surgical adjuncts like local osteo enhancement procedure (LOEP) and AgN1 are still not very often used in clinical work. Furthermore, there are still no established indication criteria for the application of AgN1. We have developed the following indications at our institution.

Material and Methods: AgN1 is approved as a void filler in the proximal femur. Since 2023, we have used AgN1 in 37 patients and 46 proximal femurs with the aim of creating an anatomical bone structure. We identified three indications and also developed a list of criteria (medical items, context factors) for the indication to perform LOEP based on pharmacological osteoporosis therapy recommendations.

Results: AgN1 was used for 3 different indications: Secondary fracture prevention after major osteoporotic fracture (MOF). As concomitant procedure in the treatment of MOF. For defect filling after osteosynthesis material removal (OSME). Important factors in decision-making were the risk of re-fracture in connection with OSME, sufficient time for informed consent in combination with emergency surgery (fracture treatment) and fracture prevention (elective). The strictest criteria were applied in elective secondary prevention due to possible complications. Decision-making aids were: MOF, a fracture under established osteoporosis therapy, history of fragility fractures, family history of osteoporosis and -associated fractures, glucocorticoid use, lifestyle (smoking and alcohol), DXA T-score < -2.5, FRAX fracture risk of > 10%, unsteady gait and tendency to fall. Ultimately, experts consisting of orthopedic surgeons and an internist decided whether surgery was indicated. Contraindications are poor general health, frailty, cognitive impairment and apparent coxarthrosis. AgN1 was used in 37 patients or 46 proximal femurs (OSME 11 patients, secondary fracture prevention 19, concomitant 6) without adverse events.

Conclusion: To date, no indication criteria for the use of AgN1, LOEP, have been defined for the clinical setting outside of studies. Our criterias may help other surgeons in the future indicating LOEP. However, surgeons must be trained in this simple but still demanding procedure. As some patients have fallen after surgery without suffering a fracture of the proximal femur, the results appear promising.

P363

SOMETHING IS NOT RIGHT! – SUBSEQUENT FRACTURES AND THERAPY GAPS

C. B. Frank[1], P. Bartusevicius[2], C. Haag[1], M. Pfefferle[1]

[1]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland; [2]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland

Objectives With secondary fracture rates reaching 5–10% or higher, Fracture Liaison Services (FLS) are essential for mitigating risk. Pharmacological interventions can reduce fractures by 20–68%. Although FLS is effective at identifying high-risk patients, the real-world efficacy of FLS in preventing recurrences is still in question.

Materials and Methods: In 2024, our FLS provided specific treatment recommendations to all 484 patients identified with osteoporosis-related fractures. Here we present our 1-year follow-up (FU) data, regarding new fractures, treatment adherence, and possible reasons for treatment failure.

Results: In 2024, 484 mostly female patients (69.2%; mean age 72.7) received a specific outpatient treatment proposal after osteoporosis assessment. Of those, only 180 received treatment. We lost 59 patients (12.2%) to FU: 4 moved, and 55 died. 57 patients (82.5% women), had at least one subsequent fracture; 8 had 2; and 3 had 3 subsequent incidents with fractures. This resulted in 57 patients with 71 events and 81 fractures. Index fracture sites were vertebral body (18; 31.6%); hip

(11; 19.3%); pelvis, pelvic ring (9; 15.8%); proximal humerus (5; 8.8%); and others (14; 24.5%). Subsequent fractures were major osteoporotic fractures (MOF) in 74.1% (60 patients), 20 were osteoporosis-related but not MOFs, and 1 resulted from adequate trauma. 27 fractures (47.4%) occurred under therapy. In 13 cases (43.3%), therapy was not initiated by general practitioners. In 2 cases (6.7%), therapy could not begin due to medical issues. 4 (13.3%) refused therapy, and in 11 cases (36.7%), the fracture occurred before the therapy appointment. Only 2 had a change in therapy after a subsequent fracture. 17/81 new fractures were proximal femur fractures, and 12 were pelvic ring fractures.

Conclusion: 11.8% fracture rate suggests that standard care often fails to address individual risk profiles. Infrastructural barriers are primary causes of delayed treatment, severely compromising patient adherence. Streamlining workflows is therefore essential for rapid therapy initiation. The incidence of proximal femur fractures underscores the limited efficacy of systemic pharmacotherapy at these specific site. This highlights a critical need for surgical adjuncts, such as local osteo-enhancement procedure, to provide immediate mechanical stability where drugs alone are insufficient.

P364

REAL LIFE DATA FROM AN ORTHOPEDIC FRACTURE LIAISON SERVICE (FLS)

C. B. Frank[1], P. Bartusevicius[2], C. Haag[1], M. Pfefferle[1]

[1]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland; [2]University Center for the Musculoskeletal System/ Dep. for Orthopedics and Traumatology of the Musculoskeletal System/ Kantonsspital Baselland Bruderholz, Baselland, Switzerland

Objectives While International Osteoporosis Foundation (IOF) sets global standards via the Best Practice Framework, local success of a Fracture Liaison Service (FLS) depends on regional networks and stakeholder integration. These factors directly influence the «therapy gap" (TG). Our orthopedic department's FLS addresses all surgical inpatients, providing structured diagnostic and treatment recommendations for follow-up (FU) care.

Materials and Methods: We prospectively screen all inpatient fractures, excluding patients under 50, those with high-energy trauma and orthogeriatric patients who start therapy during hospital stay. The remaining undergo osteoporosis assessment, including dental status, laboratory findings, medical history, comorbidities, previous fractures, menopause, lifestyle, and family history. FLS offers individualized diagnostic and therapeutic proposals. During 1-year FU, we check whether recommendations had been implemented. Other questions concern DXA, specific therapy, new fractures, adverse events, mortality, and involved specialists.

Results: In 2024, we treated over 1300 inpatient fractures. After excluding 291 orthogeriatric patients and others 484 underwent specific osteoporosis assessment (mean age 72.7), all having osteoporosis (37%). 335 (69.2%) were female. Lost to FU was 4/484 (0.82%). 55 (11.4%) died in the first year. 58 (12%) needed dental therapy. DXA was proposed in 444, performed in 208, (46.8%). 40 had no DXA indication. 34 (7.7%) declined DXA and in 80 it was not indicated due to further physicians (18%). In 122 reason for missing DXA remains unclear (27.5%). 180/484 (37.2%) had therapy. Non-initiation included patient refusal (41; 8.5%), contraindications despite willingness (7; 5.6%) and refusal by GP (119; 24.6%). Different human factors led to non-initiation in 20 (4.1%). Diagnostic gap (DG) was 53.2%; TG 62.8%. TG calculated with deceased patients, patients lost to follow-up, waiting for dental therapy, with contraindications and "overruled" indication by GPs was 27.4% (68/180). How DG and (estimated) first year mortality influence TG remains unclear.

Conclusion: TG is not just a service failure; it reflects complex correlations between human factors, clinical judgment, patient preferences, and contraindications. While FLS coordinates care, final decisions must involve primary care physicians and patient-centered context. Thus, the gap functions less as a rigid metric and more as a guiding framework for integrated, individualized treatment.

GLP-1 RECEPTOR AGONISTS AND MUSCULOSKELETAL OUTCOMES: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

C. Beaudart[1], Y. Malréchauffé[1], S. van Heden[1], D. Sanchez-Rodriguez[2], A. Scheen[3], O. Bruyère[4], A. Mobasheri[5], G. Duque[6], R. Rizzoli[7], J.-Y. Reginster[8]

[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), Research Institute for Life Sciences (NARILIS), University of Namur, Namur, Belgium; [2]Department of Geriatrics, Brugmann University Hospital, Université Libre de Bruxelles, Bruxelles, Belgium; [3]Division of Diabetes, Nutrition and Metabolic Disorders, Department of Medicine, CHU Liège, Liège, Belgium; [4]Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium; [5]Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu, Finland; [6]Bone, Muscle & Geroscience Group, Research Institute of the McGill University Health Centre, Montréal, Canada; [7]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland; [8]Department of Biochemistry, College of Science, King Saud University, Riyadh, Saudi Arabia

Introduction: This systematic review/meta-analysis aims to synthesize clinical data on the effects of Glucagon-like peptide-1 (GLP-1) receptor agonists (RAs) on key relevant bone, muscle, and joint outcomes. The primary objective is to establish whether these agents are safe for the musculoskeletal system; secondarily, the study examines their potential protective role in mitigating age- and disease-related decline and in improving some key relevant outcomes in musculoskeletal health.

Methods: MEDLINE, Cochrane Central Register of Controlled Trials (CENTRAL) (both via Ovid® platform) and Embase were searched in March 2025 to identify relevant randomized controlled trials (RCTs) or real-world evidence (RWE) studies to be included. This bibliographic search was completed with manual search. A random-effect model meta-analysis was performed for any outcome reported in at least 2 studies. Subgroup analyses were performed on the type of GLP-1 RAs, type of comparator used and study design. Sensitivity analyses were performed to test the robustness of the data. This work has been performed in adherence with PRISMA statement. (PROSPERO Record ID: CRD420251024082).

Results: From 1,148 potentially relevant references, 61 articles (47 RCTs, 13 RWE studies and 1 pharmacovigilance study, combining a

total of 1,250,778 individuals) met the inclusion criteria. Different GLP1-RAs were represented across the panel of studies i.e., semaglutide, liraglutide, exenatide, dulaglutide, and tirzepatide (dual agonist GIP/GLP-1), as well as others such as albiglutide, lixisenatide, and SAR425899 (bamadutide). No effect on bone outcomes (i.e., bone mineral density (all sites) and fractures (all sites) were observed when models included the most adjusted effect size. Regarding muscle outcomes, a significant decrease of lean body mass/fat-free mass was consistently observed with GLP1-RAs in the global model (k=28, SMD0.52, 95%CI -0.8; -0.23, I^2 88%, p-value for heterogeneity <0.0001), which remained robust in all sensitivity analyses. Subgroup analyses showed that the effect was mainly driven by liraglutide and semaglutide, with a decrease in lean body mass/fat-free mass observed when GLP-1 RAs were compared with placebo. No publication bias was found. Regarding joint outcome, models revealed no significant change in WOMAC pain, physical function and stiffness.

Conclusion: This meta-analysis is the first to investigate the effects of GLP-1 RAs on a large panel of musculoskeletal health outcomes. While no effect on bone outcomes and joint outcomes was found, effects on muscle mass outcomes (i.e., decrease of lean body mass/fat-free mass) were observed, apparently in line with body weight reduction. The clinical relevance of these results needs to be firmly established. Further studies in this field, including those looking at muscle function and using multivariate models considering confounding are needed to better reinforce the models and final findings.

EFFECTS OF ROMOSOZUMAB AND TERIPARATIDE ON BONE CALLUS FORMATION ENHANCEMENT AFTER INTRAMEDULLARY NAILING IN OSTEOPOROTIC PATIENTS WITH INTERTROCHANTERIC FRACTURES: A COMPARATIVE STUDY

C. C. Coppola[1], R. A. Randazzo[2], B. A. Balzano[3], A. D. Agnusdei[4]

[1]Dept. of Orthopedics & Traumatology, Trauma Center 'Ospedale del Mare' General Hospital, ASL NA1 Center, Italian NHS, Naples, Italy, Napoli, Italy; [2]Dept. of Rehabilitation Medicine, Trauma Center 'Ospedale del Mare' General Hospital, ASL NA1 Center, Italian NHS, Naples, Italy, Napoli, Italy; [3]Dept. of Economics & Law, University of Cassino (FR), Italy, Cassino, Italy; [4]Indipendent Scientific Consultant, Siena, Italy

INTRODUCTION

Intertrochanteric fragility fractures in osteoporotic patients are associated, one year after surgical treatment, with high morbidity and delayed fracture healing due to impaired bone metabolism. Intramedullary nailing is the standard procedure, however, enhancement of bone callus formation remains a critical determinant of successful fracture union. Bone anabolic agents, such as Romosozumab (ROMO) and Teriparatide (TPTD) besides preventing a new fracture, have also shown potential to improve bone healing, but comparative data in these patients are limited. The aim of the present study was to compare the effects of ROMO versus TPTD on bone callus formation and the fracture healing process.

MATERIALS AND METHODS

This 12 months study was performed at the Trauma Center of "Ospedale del Mare" in Naples, Italy. Sixty postmenopausal women (age 67-83), were selected for the study; other inclusion criteria were: BMI 23-26, BMD T-score between -2.5 and -4, ASA score 2, and an AO31 A2-A3 femoral fracture type.

The study population was divided into two groups: 30 patients were treated with ROMO 210 mg/month sc, and 30 patients with TPTD 20 mcg/day sc, respectively.

X-rays were performed to evaluate callus formation and progression to fracture union by the mRUST score (modified Radiographic Union Scale for Tibia) adapted for femur at predetermined intervals (3-6-12 months).

Adapted Femoral mRUST Score PROFORMA

SECTION 1 – Patient Demographics

Variable	Value
Patient Study ID	_____
Age (years)	_____
Sex	☐ Male ☐ Female
BMI (kg/m²)	_____
Affected side	☐ Left ☐ Right
Date of injury	____ / ____ / _____
Mechanism of injury	☐ Low-energy fall ☐ Other: _____

SECTION 2 – Baseline Clinical Characteristics

Variable	Value
Osteoporosis diagnosed	☐ Yes ☐ No
DEXA available	☐ Yes ☐ No
If yes – T-score	_____
ASA score	☐ I ☐ II ☐ III ☐ IV
Relevant comorbidities	☐ Diabetes ☐ Smoking ☐ CKD ☐ Steroid use ☐ Other:

SECTION 3 – Fracture Characteristics

Variable	Value
AO/OTA classification	☐ 31-A1 ☐ 31-A2 ☐ 31-A3
Stability	☐ Stable ☐ Unstable
Comminution	☐ Yes ☐ No
Reduction quality	☐ Good ☐ Acceptable ☐ Poor

SECTION 4 - Surgical Details

Variable	Value
Date of surgery	____ / ____ / _____
Time from injury to surgery (days)	_____
Implant type	☐ Short IM nail ☐ Long IM nail
Cephalomedullary device	☐ Yes ☐ No
Distal locking	☐ Static ☐ Dynamic
Intraoperative complications If yes, specify	☐ Yes ☐ No _____

SECTION 5 – Postoperative Management

Variable	Value
Weight bearing	☐ Immediate WBAT ☐ Partial ☐ Delayed
Osteoporosis treatment initiated If yes	☐ Yes ☐ No ☐ Bisphosphonates ☐ Denosumab ☐ Teriparatide ☐ Romosozumab
Rehabilitation protocol	☐ Standard ☐ Modified

SECTION 6 – Radiographic Assessment Schedule

3-Month Follow-up

Cortex	Score (1–4)
Medial	☐1 ☐2 ☐3 ☐4
Lateral	☐1 ☐2 ☐3 ☐4
Anterior	☐1 ☐2 ☐3 ☐4
Posterior	☐1 ☐2 ☐3 ☐4
Total mRUST (4–16)	_____

6-Month Follow-up

Cortex	Score (1–4)
Medial	☐1 ☐2 ☐3 ☐4
Lateral	☐1 ☐2 ☐3 ☐4
Anterior	☐1 ☐2 ☐3 ☐4
Posterior	☐1 ☐2 ☐3 ☐4
Total mRUST (4–16)	_____

12-Month Follow-up

Cortex	Score (1–4)
Medial	☐1 ☐2 ☐3 ☐4
Lateral	☐1 ☐2 ☐3 ☐4
Anterior	☐1 ☐2 ☐3 ☐4
Posterior	☐1 ☐2 ☐3 ☐4
Total mRUST (4–16)	_____

SECTION 8 – Healing Interpretation

Time Point	Healing Status
3 months	☐ Poor ☐ Progressive ☐ Advanced
6 months	☐ Delayed ☐ Progressive ☐ Advanced
12 months	☐ Union ☐ Delayed union ☐ Non-union

SECTION 9 – Complications and Reoperations

Variable	Value
Mechanical failure	☐ Yes ☐ No
Cut-out / Cut-through	☐ Yes ☐ No
Non-union	☐ Yes ☐ No
Reoperation required If yes, reason	☐ Yes ☐ No _____

RESULTS

Patients treated with ROMO, six months after surgery, demonstrated a significantly higher mRUST scores compared with those receiving TPTD

(13.7 ± 1.3 vs 12.2 ± 1.4, p<0.01), indicating earlier cortical bridging and enhanced radiographic callus maturation; these differences were reduced at 12 months.

Radiographic Bone Healing Assessed by mRUST Score after Intramedullary Nailing of Intertrochanteric Fractures

Comparison between Romosozumab and Teriparatide Groups

Outcome	Time Point	Romosozumab (n = 30)	Teriparatide (n = 30)	Mean Difference (95% CI)	p value
mRUST score (mean ± SD)	3 months	10.5 ± 1.5	9.3 ± 1.6	1.2 (0.5 to 1.9)	0.002
	6 months	13.8 ± 1.3	12.3 ± 1.4	1.5 (0.9 to 2.1)	<0.001
	12 months	15.4 ± 0.8	14.9 ± 1.0	0.5 (−0.1 to 1.0)	0.081
Patients with ≥3 bridged cortices, n (%)	3 months	19 (63%)	13 (43%)	—	0.11
	6 months	25 (83%)	18 (60%)	—	0.041
	12 months	29 (97%)	28 (93%)	—	0.55
Radiographic union achieved, n (%)	6 months	23 (77%)	19 (63%)	—	0.26
	12 months	29 (97%)	28 (93%)	—	0.55
Time to radiographic union (months, mean ± SD)	—	5.4 ± 1.1	6.3 ± 1.4	−0.9 (−1.5 to −0.3)	0.004

Data are presented as mean ± standard deviation or number (percentage). mRUST, modified Radiographic Union Score for Tibial fractures. Between-group comparisons were performed using independent t-tests or Mann–Whitney U tests for continuous variables and chi-square or Fisher's exact tests for categorical variables. A two-sided p-value < 0.05 was considered statistically significant.

CONCLUSIONS

In osteoporotic patients, following intramedullary nailing of intertrochanteric fragility fractures, Romosozumab may promote a more rapid and pronounced bone callus formation than Teriparatide. Further randomized controlled studies are needed to confirm these results and define optimal treatment protocols.

HUMAN UCMSC-DERIVED EXOSOMES ENHANCE KNEE FUNCTION AND ATTENUATE OSTEOARTHRITIS PROGRESSION IN A PRECLINICAL ANIMAL STUDY

C. Chen[1], Y. Lin[2], S. Chuang[3], S. Lin[2], Y. Kao[3]

[1]Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan; [2]Koahsiung Medical University, Kaohsiung City, Taiwan; [3]Kaohsiung Medical University, Kaohsiung City, Taiwan

Background: Mesenchymal stem cells (MSCs) show therapeutic potential in osteoarthritis (OA), but their clinical use is limited by low cell yield and the need for extensive ex vivo expansion. Exosomes derived from human umbilical cord MSCs (UCMSCs) represent a promising cell-free alternative with comparable regenerative and anti-inflammatory properties.

Methods: UCMSC-derived exosomes (UCMSC-Exos) were isolated and characterized by nanoparticle tracking analysis. Their in vitro effects were assessed in IL-1β–stimulated chondrocytes via mRNA expression profiling and Alcian blue staining. In vivo efficacy was evaluated in a rat anterior cruciate ligament transection (ACLT) model using functional assessments and histological analyses.

Results: UCMSC-Exos suppressed catabolic markers (IL-1β, MMP-3, Col X) and increased anabolic markers (TIMP-1, aggrecan, Col II) in chondrocytes. Intra-articular administration of UCMSC-Exos attenuated OA progression, improving gross joint morphology and reducing cartilage degeneration. Treated knees showed higher glycosaminoglycan and Col II content and reduced MMP13 expression. Functionally, UCMSC-Exos improved weight-bearing symmetry and treadmill endurance after ACLT.

Conclusion: UCMSC-derived exosomes mitigate IL-1β–induced chondrocyte inflammation, promote matrix synthesis, and reduce catabolic activity. In vivo, they preserve cartilage integrity and enhance knee function following joint injury. These findings support UCMSC-Exos as a promising cell-free therapeutic strategy for OA.

AUTOMATED DEEP LEARNING ESTIMATION OF BONE MINERAL DENSITY AND T-SCORE FROM RADIOGRAPHS FOR ENHANCED BONE HEALTH ASSESSMENT

C. Chui[1], L. Liu[2], X. Xie[2], W. Wong[1], Y. Yung[1], C. Cheung[1]

[1]CUHK, N.T., Hong Kong SAR China; [2]CUHK, N.T., China

Abstract

Objective(s): Osteoporosis is widely prevalent worldwide, characterized by decreased bone mineral density (BMD) and an increased risk of fractures. Accurate assessment of BMD and T-scores is crucial for early detection, intervention, and risk stratification. This study aims to develop a non-invasive deep learning-based method capable of predicting BMD and T-scores from routine radiography, enabling broader and lower-cost bone health screening and improving early screening coverage at the public health level.

Material and Methods: To overcome the reliance of traditional BMD measurements on specialized equipment and trained operators, we propose a multi-model fusion deep learning framework. The framework integrates three convolutional neural networks (Xception, EfficientNetV2S, and MaxBlurPooling model) and fuses their predictions via a simple average to improve accuracy and stability. The dataset spans multiple centers, comprising 5,000 radiographies, and is split into training, validation, and external evaluation stages. Evaluation metrics include Pearson correlation coefficient (r) and area under the receiver operating characteristic curve (AUC), simultaneously assessing BMD prediction, T-score inference, and osteoporosis classification performance. Additionally, the study analyzes the impact of inter-center data distribution on predictive robustness to provide evidence for applicability across diverse populations and devices.

Results: On the internal dataset, the model achieved a r = 0.86; on the external validation set, r = 0.82, with osteoporosis classification AUCs reaching up to 0.90, indicating robust predictive performance and good generalization. Further analyses show that despite distribution differences across centers, the model maintains stable predictive confidence across multiple imaging devices and acquisition conditions. Compared with traditional screening, the method offers clear advantages in cost, accessibility, and turnaround time, supporting broad applicability in clinical practice and public health settings.

Conclusion(s): These results demonstrate the potential of this AI-driven, non-invasive approach as a cost-effective adjunct for opportunistic osteoporosis screening, complementing DXA in settings with limited access and addressing population-specific needs in Asian cohorts.

P369

AI AND LLM-INTEGRATED REVERSE SHOULDER ARTHROPLASTY PLANNING IMPROVES EFFICIENCY, IMPLANT POSITIONING, AND SAFETY: A COMPARATIVE STUDY

C. Chui[1], X. Xie[2], L. Liu[2], W. Wong[1], Y. Yung[1]

[1]CUHK, N.T., Hong Kong SAR China; [2]CUHK, N.T., China

Objective(s):
Develop and evaluate a fully offline AI- and large language model (LLM)-integrated Reverse shoulder arthroplasty (RSA) planning system to enhance efficiency, accuracy, and safety vs conventional manual planning.
Material and Methods:
We built an integrated RSA planning platform combining automated 3D reconstruction, landmark detection and measurement, implant and screw trajectory optimization, and dynamic impingement assessment. Scapula and humerus segmentation was performed using nnU-Net v2 for 3D reconstruction. Landmark detection employed principal component analysis and power iteration for axis estimation with sphere fitting for joint geometry. For scapular screw planning, multiple spiral trajectories were evaluated at 15° intervals using Rodrigues rotation, selecting the longest intraosseous path. Bony impingement was assessed by collision detection. An LLM assistant (Llama-2-7B) was fine-tuned using low-rank adaptation (LoRA, rank=8) on 5,000 surgical commands to enable multilingual function calling and interactive implant adjustment. Planning performance was compared with a manual workflow using standard commercial tools (segmentation, implant positioning, screw planning, and surgical guide design).
Results:
AI/LLM markedly improved planning efficiency (AI < 9 minutes vs manual ≥ 25 minutes; 64% faster, $p<0.001$). Implant positioning accuracy favored AI (mean angular error 2° vs 5°, $p<0.01$). Screw trajectory safety improved (cortical breach <1% AI vs 20% manual, $p<0.05$). Dynamic impingement gain: +15° in impingement-free elevation ($p<0.05$). Landmark measurements: glenoid center 4.83 mm, radius 2.51 mm, orientation 5.92°, retroversion 5.20°, inclination 4.30°. The LLM module achieved 95.2% task completion with 93.75% function call accuracy across 160 command sets in English and Chinese (Putonghua and Cantonese).
Conclusion(s):
Fully offline AI- and LLM-integrated RSA planning significantly enhances efficiency, implant alignment, and screw trajectory safety relative to manual planning. The multilingual LLM assistant enables intuitive adjustments while preserving surgeon control, supporting standardized, faster, and safer shoulder arthroplasty workflows

P370

LOOK THRICE BUT FRACTURE ONCE- A CLOSED LOOP THREE CYCLE AUDIT OF BONE PROTECTION PRESCRIPTION POST HIP FRACTURE AT DISCHARGE AND 12 MONTHS LATER IN A MODEL FOUR HOSPITAL ON THE ATLANTIC COAST

C. Conlon[1], C. Clancy[1], C. Armstrong[1], R. Waters[1]

[1]University Hospital Galway, Galway, Ireland

Objective
To assess practice of prescribing of bone protective treatment in a post hip fracture patient cohort at the time of discharge and at one year post discharge, assessing at three time points.
Material and Methods
A closed loop three phase audit in the form of a retrospective review of bone protection post hip fracture was undertaken in a model four hospital in Ireland. The Plan-Do-Study-Act tool was utilised to guide this audit, the standard being audited against was the fifth Irish Hip Fracture Standard (IHFS). Each cycle of the audit looked at a one month period namely August of 2021, 2022 and 2024 with follow up at one year to assess adherence. The inclusion criteria being aged sixty-five or above with a hip fracture within the time period of the study, those with fracture of shaft of femur were excluded.
Results
There were 32 patients in the first cycle of the audit, 18 patients in the second cycle and 17 in the third cycle of the audit. The majority of the cohort in the first and second cycle were female, 23(74%) and 16(89%), with the majority being male in the third cycle 9(53%) with mean age of 82 years. The first cycle demonstrated that 21(65%) were prescribed bone protective treatment with 8(31%) on treatment one year post hip fracture. The second cycle demonstrated that 9(50%) were initiated on bone protection on discharge with 7(78%) on treatment at the one year juncture. The third cycle showed that 14(82%) were prescribed bone protective treatment on or before discharge with 7(50%) on treatment one year post hip fracture.
Conclusions
This audit demonstrates suboptimal adherence to the IHFS and will serve as the catalyst for rethinking our orthogeriatric service with an emphasis on education of staff along with improving communication with community colleagues on the need for ongoing active management of these patients. Of note the second cycle demonstrates that whilst prescription of bone protection has disimproved adherence for those prescribed these agents has in fact improved since the first cycle. The third cycle demonstrates similar adherence with the standard as in the second cycle but disimproved long term adherence.

P371

INVESTIGATION OF THE SAFETY AND EFFICACY OF A SINGLE INTRA-ARTICULAR INJECTION OF SINOGEL® FOR THE MANAGEMENT OF KNEE OSTEOARTHRITIS

C. Costantino[1], M. A. Minetto[2], C. Melchior[3], S. Bernasconi[4], A. Massè[5], M. Fortina[6], A. Loro[7,8], S. Masiero[9], F. Quattrini[10,11]

[1]Department of Medicine and Surgery, University of Parma, Parma, Italy; [2]Division of Physical Medicine and Rehabilitation, Department of Surgical Sciences, University of Turin, Turin, Italy; [3]Azienda ULSS 2 Marca Trevigiana, Conegliano Hospital, Conegliano (TV), Italy, Conegliano, Italy; [4]Villa Aprica Clinical Institute, San Donato Group, Como, Italy; [5]Department of Orthopaedic Surgery and Traumatology, Città Della Salute e Della Scienza Torino-CTO, Turin, Italy; [6]Department of Orthopaedics and Traumatology, University Hospital of Siena, Siena, Italy; [7]Physical and Rehabilitation Medicine, Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy; [8]Physical and Rehabilitation Medicine Unit, Maggiore della Carità University Hospital, Novara, Italy; [9]Department of Neurosciences, Neurorehabilitation Unit, University Hospital of Padua, Padua, Italy; [10]University of Parma, Parma, Italy; [11]Orthopaedics and Traumatology Department, Guglielmo da Saliceto Hospital, Piacenza, Italy

The objectives for this study were i) to investigate the safety and local tolerance of Sinogel® administered by intra-articular (IA) injection to the knee and ii) to evaluate its effect upon knee pain.
Sinogel®, is medical device containing sodium hyaluronate 2.4% and sodium chondroitin 1.6%, indicated for pain or reduced mobility due to degenerative affections, post-traumatic disorders or joint alterations. In this open-label multicentre prospective study, 82 patients with knee osteoarthritis (OA) received a single 3ml IA injection of Sinogel®. Principal eligibility criteria were age ≥45 and ≤80 years; Kellgren-Lawrence Grade 2 to 3 severity OA of the knee and moderate pre-treatment pain intensity defined as a Visual Analogue Scale (VAS) score ≥50mm on a 0-100mm VAS for pain. After informed consent, screening and treatment (Day 0) patients attended for up to 4 in-person visits 1, 2, 4 weeks and 6 months after IA injection, plus a phone follow-up at 3 months.
A total of 82 of 89 patients screened were included and received treatment – 81 completed follow-up. Sinogel® was well tolerated, with no serious adverse events (SAEs) or device deficiencies reported. Treatment-emergent adverse events (TEAEs) occurred in 41.5% of patients, but all were mild or moderate in intensity. Adverse device effects (ADEs) were reported in 7.3% of patients, none were severe. All ADEs resolved within 3 days. No significant changes in erythema, swelling, hardening, or injection site pain were observed after treatment. No significant changes in vital signs (systolic blood pressure, diastolic blood pressure and heart rate), weight, or severe local reactions were reported.
Significant pain reduction was observed over 6 months. The mean (SD) VAS score decreased from 67.5 (10.4) mm at baseline to 14.5 (16.3) mm at 6 months ($p<0.0001$). Use of rescue medication (paracetamol) was limited, with 59.8% of patients taking at least 1 dose during the study.
Sinogel® demonstrated a favourable safety and tolerability profile, with minimal adverse effects and no SAEs. The device effectively reduced knee pain, with sustained improvement over 6 months. Although uncontrolled, the results support the safety and efficacy of Sinogel® for treating knee OA.

P372

SKELETAL IMPACT OF PARATHYROID SURGERY IN PATIENTS EVALUATED IN A RHEUMATOLOGY SETTING

C. Demory[1], C. Marciniak[1], M. Gobert[1], G. Baud[1], M. Chetboun[1], B. Cortet[1], R. Caiazzo[1], F. Pattou[1]

[1]Lille University Hospital, Lille, France

Background: Mild Primary Hyperparathyroidism (MPH), whether normocalcemic or not, is frequently identified within rheumatology pathways but remains poorly characterized. In these forms, the skeletal benefit of parathyroidectomy is uncertain. Better defining its impact may help clarify the value of surgery beyond biochemical cure alone.
Methods: we conducted a single-center retrospective study between 2011 and 2024, including patients initially evaluated in rheumatology for skeletal involvement and subsequently operated on for MPH (total calcium ≤ 110 mg/l). The skeletal impact of parathyroidectomy was assessed at 2 years on lumbar spine and total hip Bone Mineral Density (BMD), two relevant sites because of their sensitivity to postoperative changes.
Results: among the 160 patients seen in rheumatology, 27 had MPH (mean total calcium 102,7 g/l; mean PTH 105 pg/ml) with skeletal involvement (osteoporosis in 81,5 %) (Table 1, Figure 1). Immediate surgical success was 100 % according to the Miami criterion (≥ 50 % PTH drop). Postoperative complications including transient hypoparathyroidism (18,5 %), transient recurrent nerve palsy (7,4 %), and one surgical site infection. At 2 years, total calcium and PTH had normalized in all patients (mean reductions of 9,3 mg/l and 64,3 pg/mL, respectively), confirming sustained biochemical cure. In contrast, BMD remained stable at both the lumbar spine and total hip, with no significant postoperative improvement (Figure 2).
Conclusion: in patients with MPH and skeletal involvement, parathyroidectomy stabilizes BMD at 2 years but does not induce measurable improvement, despite complete biochemical normalization. These findings suggest that the skeletal benefits of surgery may be limited in mild forms.

Variables	All n = 27 (%)

RETROSPECTIVE ANALYSIS OF ADULT PATIENTS WITH LOW ALKALINE PHOSPHATASE LEVELS

C. Dincer Yazan[1], D. Gogas Yavuz[1]

[1]Marmara university Faculty of Medicine, Pendik Research and Training Hospital, Istanbul, Türkiye

Objectives: Low serum alkaline phosphatase (ALP) level is a hallmark of hypophosphatasia, but may also be associated with some secondary causes. Low ALP levels may frequently remain unrecognized and therefore not undergo further diagnostic evaluation. Identifying the patients with persistently low ALP levels is important for diagnosis of adult onset hypophosphatasia.

Methods: Low readings of ALP levels, under 30 IU/L in the recent year were evaluated. Medical records of patients with low ALP levels were extracted. Comorbidities, medications, calcium, inorganic phosphor, magnesium parathormone levels were recorded from files.

Results: Medical records of 294 patients with ALP levels under 30 IU/L within the last year were analyzed. 219 were female and 75 were male. The mean age of the group was 40.2 years. 18 patients had inflammatory diseases (inflammatory bowel disease, rheumatologic diseases), 23 patients had malignancy, 7 patients were under antiresorbtive drugs, 7 patients had chronic kidney disease, 1 patient had chronic liver disease. 20 patients were analyzed as low ALP levels during hospitalisation/intensive care unit admittance. 13 patients were under steroid treatment. 4 patients had bariatric surgery and 6 patients had severe hypertriglyceridemia. All of the patients had normal calcium and phosphor levels. 171 patients had low ALP with repeated measurements. 58 patients had persistently low ALP levels without identifiable secondary cause in medical records. One patient had daughter with known odontohypophosphatasia, the patients' genetic result is unknown. Two patients were referred for genetic evaluation recently. There were 4 patients diagnosed as hypophosphatasia in adulthood period. One patient who was diagnosed at 64 years old due to low ALP levels and atypical femoral fractures and through family evaluation, two daughters of her were diagnosed as hypophosphatasia. They had no dental problems but they had fatigue and chronic pain. One 45 year old female patient was diagnosed as hypophosphatasia after evaluation due to persistently low ALP levels and poor dental history beginning in childhood period. 54 of these patients were not evaluated for persistantly low ALP levels.

Discussion: Adult onset hypophosphatasia is a rare disorder and due to non-specific clinical manifestations may frequently be underdiagnosed. Low ALP levels are frequently under recognized. Being aware of persistently low ALP levels in patients without secondary causes is important to identify adult onset hypophosphatasia particularly in clinically mild phenotypes.

P374

BUROSUMAB IS ASSOCIATED WITH A DECREASED FREQUENCY OF HYPERTENSION IN ADULTS WITH X-LINKED HYPOPHOSPHATEMIA

C. Grimbly[1], K. Young[1], J. Ringrose[1], P. Mandhane[1], L. M. Ward[2], R. T. Alexander[1]

[1]University of Alberta, Edmonton, Canada; [2]University of Ottawa, Ottawa, Canada

Introduction:
X-linked Hypophosphatemia (XLH) is characterized by elevated FGF23 levels resulting in renal phosphate wasting and osteomalacic bone disease. Treatment options include burosumab, an FGF23 neutralizing antibody which improves renal phosphate reabsorption. XLH is a multi-system disease with increasingly recognized cardiovascular risk factors including obesity and hypertension (HTN). This study aimed to identify the frequency of HTN in adults with XLH and associated risk factors.
Methods:
We examined adult blood pressure (BP) data from the multinational prospective outcomes in XLH Disease Monitoring Program (NCT03651505) and the randomized control trial, burosumab vs conventional therapy (NCT02312687 / 02526160). BP was collected during study visits.
Hypertension (HTN) was defined as systolic BP≥140 mmHg or diastolic BP≥90 mmHg as per the International Society of Hypertension. Clinical parameters including age, sex, body mass index (BMI), parathyroid hormone (PTH) levels and treatment were assessed for association with HTN. Clustered cohort data were analyzed using a generalized estimated equation.
Results:
The study included 359 participants (252 female, 70%) with a median age of 39.7 years (IQR 30.4, 50.0) at first BP measurement. A total of 5,804 BPs were collected over 4.95 years (IQR 2.36, 5.39). Burosumab therapy increased from 18% (66/359) at study initiation to 99% (356/359) at study completion, with a median treatment duration of 3.74 years (IQR 1.86–5.55). Overall, 16% of BP measurements (922/5,804) met criteria for hypertension. Systolic blood pressure was ≥130 mmHg in 29% of measurements (1,715/5,804) and ≥140 mmHg in 11% (657/5,804).
Multivariable analysis identified that older age (OR 1.02, p<0.001, 95%CI CI 1.01-1.04), male sex (OR 1.64, p=0.002, 95%CI 1.20-2.25), increased BMI (OR 1.06, p<0.001, 95%CI 1.04-1.07) and serum PTH levels (OR 1.02, p=0.02, 95%CI 1.00-1.03) were independently associated with HTN. Conversely, burosumab treatment was associated with a decreased odds of HTN (OR 0.68, p<0.001, 95% CI 0.57-0.81).
Conclusions:
Adults with XLH have a frequency of HTN comparable to that of the general population and share similar associated risk factors including older age, male sex, and higher BMI and PTH levels. Burosumab was associated with a 32% reduction in HTN, an observation which merits further study to determine the mechanism of this finding.

P375

CLINICAL AND DENSITOMETRIC PROFILE OF OSTEOPOROSIS IN RHEUMATOID ARTHRITIS: SEX-RELATED DIFFERENCES IN REAL-WORLD PRACTICE

C. H. Knani[1], R. Grassa[1], M. Ghali[1], N. Ben Chekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Monastir, Monastir, Tunisia

Introduction :
Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with an increased risk of osteoporosis and fragility fractures. Bone loss in RA results from multifactorial mechanisms, including systemic inflammation, disease duration, functional disability and long-term glucocorticoid exposure. Although female sex is traditionally considered a major risk factor for osteoporosis, sex-related differences in bone involvement among patients with RA remain insufficiently characterized in real-world clinical settings. The aim of this study was to analyze the clinical and densitometric profile of osteoporosis in RA according to sex and to identify associated factors.

Methods :
This was a retrospective, single-center study including patients with RA fulfilling the 2010 ACR/EULAR classification criteria. Collected data included demographic characteristics, body mass index (BMI), disease duration, disease activity assessed by DAS28, and exposure to glucocorticoids.
Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) at the lumbar spine and femoral neck. Osteoporosis was defined by a T-score ≤ −2.5 and/or the presence of fragility fractures. Clinical and densitometric characteristics were analyzed according to sex.

Results :
A total of 118 patients with RA were included, comprising 99 women and 19 men (female-to-male ratio = 5.2). The mean age was 56.9 ± 11.6 years, and the mean disease duration was 12.1 ± 5.5 years. The mean BMI was 29.2 ± 5.1 kg/m², with 70.7% of patients being overweight or obese.
Disease activity was high, with a mean DAS28 of 5.66 ± 1.09 and a mean C-reactive protein level of 29.3 mg/L. Mean BMD T-scores were −1.8 ± 1.44 at the lumbar spine and −1.5 ± 1.43 at the femoral neck.
Osteoporosis was diagnosed in 47% of patients and was significantly more prevalent in women than in men (p = 0.015), demonstrating a significant association between female sex and osteoporosis in RA. Women showed predominantly lumbar spine involvement, whereas men presented greater femoral neck impairment.
Fragility fractures were observed in 16.9% of patients (6.8% femoral fractures, 6.8% vertebral fractures, and 3.4% wrist fractures), occurring more frequently in women (p = 0.02). Osteoporosis was significantly associated with older age, longer RA duration, higher inflammatory activity, and glucocorticoid exposure (p < 0.05).

Conclusion :
Osteoporosis is a frequent complication of rheumatoid arthritis and is significantly associated with female sex, with distinct densitometric and fracture patterns according to sex. These findings highlight the importance of systematic bone health assessment in patients with RA, integrating sex and inflammatory burden to improve fracture risk prevention strategies.

P376

SEX AS A DETERMINANT OF COMORBIDITY PROFILE AND THERAPEUTIC RESPONSE IN RHEUMATOID ARTHRITIS

R. Grassa[1], C. H. Knani[1], N. Ben Chekaya[1], M. Ghali[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Monastir, Monastir, Tunisia

Introduction: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease frequently associated with multiple comorbidities that may influence disease severity, functional outcomes, and therapeutic response. Sex-related biological and behavioral differences may contribute to variations in comorbidity patterns and their clinical impact. Understanding these differences is essential for optimizing personalized management strategies in RA. This study aimed to investigate sex-related differences in comorbidity profiles among patients with RA and to evaluate their impact on disease activity and therapeutic response.

Methods: We conducted a retrospective, single-center study including patients diagnosed with RA according to the 2010 ACR/EULAR classification criteria. Comorbidities assessed included major cardiovascular risk factors (hypertension, diabetes mellitus, and smoking) and osteoporosis. Comparative analyses were performed according to sex to evaluate differences in comorbidity prevalence and their association with disease activity and treatment response. Disease activity was assessed using the Disease Activity Score in 28 joints (DAS28), inflammatory burden by C-reactive protein (CRP), pain by visual analog scale (VAS), and functional disability by the Health Assessment Questionnaire (HAQ). Multivariate analysis was performed to identify independent predictors of therapeutic response.

Results: A total of 118 patients were included, comprising 99 women and 19 men (male-to-female ratio = 0.19). The mean age was 56.9 ± 11.6 years, and the mean disease duration was 12.1 ± 5.5 years.Osteoporosis was the most prevalent comorbidity, affecting 47% of patients, and was significantly more frequent in women than in men (65% vs. 35%, $p < 0.0001$). Diabetes mellitus was present in 34.7% of patients, with no significant sex difference (18% in women vs. 16% in men, $p = 0.63$). Hypertension was observed in 33.1% of patients and was more prevalent in women (37% vs. 25%, $p = 0.01$). Active smoking was significantly more frequent in men compared to women (53% vs. 4%, $p < 0.0001$).Disease activity was high, with a mean DAS28 of 5.66 ± 1.09 and a mean CRP level of 29.3 mg/L, reflecting substantial inflammatory burden. The mean pain VAS score was 52.5 ± 20.3 mm, and the mean HAQ score was 1.66 ± 0.85, indicating moderate to severe functional impairment.

Multivariate analysis demonstrated that osteoporosis ($p = 0.01$), cardiovascular risk factors ($p < 0.01$), and active smoking ($p < 0.01$) were independently associated with poorer therapeutic response, regardless of age, sex, or baseline inflammatory activity. These findings suggest that comorbidities significantly contribute to disease severity and may negatively influence treatment outcomes.

Conclusion: Comorbidities are highly prevalent in patients with RA and significantly influence disease severity and therapeutic response. Sex-related differences in comorbidity profiles, particularly osteoporosis and smoking, highlight the importance of comprehensive, individualized assessment. Integrating comorbidity management into routine RA care may improve therapeutic outcomes and support a more personalized treatment approach.

P377

FROM BELIEFS TO BEHAVIOR: BARRIERS SHAPING PHYSICAL ACTIVITY ENGAGEMENT IN CHRONIC INFLAMMATORY DISEASES

C. H. Knani[1], M. Ghali[1], R. Grassa[1], N. Ben Chekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Monastir, Monastir, Tunisia

Background

Chronic inflammatory rheumatic diseases (CIRD) are characterized by chronic inflammation and functional impairment, often leading to physical inactivity. Evidence supports that regular physical activity improves physical function, reduces disability, and enhances quality of life in this population.

Objectives

To evaluate physical activity levels in patients with chronic inflammatory rheumatic diseases (CIRD) and to identify key perceived barriers and patient beliefs related to exercise participation.

Methods

We conducted a cross-sectional study including patients followed for chronic inflammatory rheumatic diseases. Sociodemographic and clinical characteristics, disease activity, pain intensity assessed by visual analog scale (VAS), and functional disability measured by the Health Assessment Questionnaire (HAQ) were collected. Physical activity levels, perceived barriers, and patient beliefs regarding exercise were assessed using a self-administered questionnaire.

Results

A total of 55 patients were included, of whom 63.3% had rheumatoid arthritis, 26.7% spondyloarthritis, and 10% psoriatic arthritis. The female-to-male ratio was 1.63, with women accounting for 70% of the cohort. The mean age was 48.4 ± 13.6 years, and the mean disease duration was 13.5 ± 5.3 years. Mean body mass index was 28 ± 3.4 kg/m², mean pain VAS score was 52.5 ± 20.3 mm, and mean HAQ score was 0.8 ± 0.4. Educational attainment was distributed as follows: university or higher (29%), secondary (22%), primary (33%), and illiteracy (16%). Regular physical activity was reported by 22% of patients. Among physically inactive patients, 90% expressed willingness to engage in exercise. The main reported barriers were joint pain (48%), lack of motivation (24%), fatigue (14%), joint deformities (10%), and limited access to appropriate facilities (5%). Patients with higher educational levels (secondary or university) were significantly more likely to engage in regular physical activity compared with those with primary education or illiteracy ($p = 0.02$). Nearly all patients (97%) perceived physical activity as beneficial and expressed interest in adapted exercise programs. Factors positively associated with favorable exercise perceptions included younger age ($p = 0.025$), higher educational level ($p = 0.04$), and higher socioeconomic status ($p = 0.02$).

Conclusions

Physical activity participation in patients with chronic inflammatory rheumatic diseases is strongly influenced by patient beliefs and perceived barriers. Higher educational and socioeconomic levels are associated with greater engagement in exercise. These findings highlight the importance of developing tailored, patient-centered physical activity programs to enhance adherence, improve functional outcomes, and optimize quality of life in this population.

P378

BEYOND PAIN: FUNCTIONAL DISABILITY AND PSYCHOLOGICAL DISTRESS IN CERVICOBRACHIAL NEURALGIA

C. H. Knani[1], D. Khalifa[1], R. Fakhfakh[1], N. El Amri[1], H. Hachfi[1], K. Baccouche[1], I. Bouagina[1]

[1]Farhat Hached hospital, Sousse, Sousse, Tunisia

Background
Cervicobrachial neuralgia (CBN), resulting from cervical nerve root compression, is a frequent cause of consultation in outpatient practice. Beyond pain and motor impairment, CBN may lead to substantial functional limitations and psychological distress, ultimately compromising patients' quality of life.
Objectives
To evaluate the extent of functional disability and psychological burden in patients with cervicobrachial neuralgia and to assess their impact on quality of life, with the aim of informing more comprehensive management strategies.
Methods
We conducted a descriptive cross-sectional study including 47 patients diagnosed with cervicobrachial neuralgia. Pain intensity was assessed using the visual analogue scale (VAS) for cervical and radicular pain. Functional disability was evaluated using the Neck Disability Index (NDI), while psychological distress was assessed using the Hospital Anxiety and Depression Scale (HADS).
Results
Forty-seven patients were included, comprising 40 women and 7 men (female-to-male ratio 5.7). The mean age was 52.3 ± 13.7 years (range 22–75), and 67.4% were professionally active. Mean disease duration was 4.34 years. The most common comorbidities were diabetes mellitus (26.2%), hypertension (7.1%), and connective tissue diseases (7.1%). Mechanical factors were predominant, with heavy load carrying (38.3%) and exposure to vibratory movements (35.2%) identified as major triggering factors. Clinical presentation was unilateral in 51.1% of cases and bilateral in 46.8%, with a non-dermatomal distribution observed in 46.8%. Mechanical pain was reported by 70.2% of patients, and cervical stiffness was present in 74.5%. The main etiologies were cervical osteoarthritis (68.1%) and cervical spinal canal stenosis (47.8%).
Mean VAS scores were 5.98 ± 1.6 for cervical pain and 6.26 ± 1.9 for radicular pain. Functional assessment revealed a mean NDI score of 34.6 ± 8, corresponding to severe disability. Psychological evaluation demonstrated a high prevalence of anxiety symptoms (HADS-A: 89.4%), exceeding that of depressive symptoms (HADS-D: 52.8%). Pain intensity was significantly correlated with functional disability ($p = 0.038$), and functional disability was significantly associated with sex ($p = 0.046$). No significant association was observed between NDI and age ($p = 0.20$) or disease duration ($p = 0.405$). Anxiety symptoms were significantly more pronounced in women than in men ($p = 0.04$).
Conclusions
Cervicobrachial neuralgia is associated with marked functional disability and a substantial psychological burden, particularly anxiety, resulting in a significant impairment of quality of life. These findings emphasize the need for a comprehensive, multidisciplinary, and personalized approach to management that integrates both physical and psychological dimensions of the disease.

P379

SEXUAL DYSFUNCTION AS AN OVERLOOKED DIMENSION OF QUALITY OF LIFE IN WOMEN WITH RHEUMATOID ARTHRITIS

C. H. Knani[1], N. El Amri[1], D. Khalifa[1], R. Fakhfakh[1], H. Hachfi[1], K. Baccouche[1], I. Bouagina[1]

[1]Farhat Hached hospital, Sousse, Sousse, Tunisia

Introduction:
Rheumatoid arthritis (RA), as a chronic inflammatory disease, has a profound impact on multiple aspects of patients' daily lives, including sexual health and intimacy. Despite its importance, sexual dysfunction remains an underrecognized and insufficiently addressed dimension of quality of life in women with RA, and is rarely evaluated systematically in routine clinical practice. The aim of this study was to assess sexual function in sexually active women with rheumatoid arthritis and to evaluate the relationship between sexual dysfunction and disease-related clinical parameters.
Methods:
We conducted a descriptive cross-sectional study including women diagnosed with rheumatoid arthritis according to the 2010 ACR/EULAR classification criteria. Sexual function was assessed using the validated Female Sexual Function Index (FSFI), a self-administered questionnaire evaluating six domains: desire, arousal, lubrication, orgasm, satisfaction, and pain. Sexual dysfunction was defined as an FSFI score <26. Fatigue was assessed using a visual analog scale (VAS), disease activity was measured using the Disease Activity Score in 28 joints (DAS28), and functional disability was evaluated using the Health Assessment Questionnaire (HAQ).
Results:
A total of 30 women were included. The mean age was 40.03 ± 8.5 years (range: 27–55), and the mean disease duration was 6.7 years. Most patients (84%) were professionally active. The most common comorbidities were diabetes mellitus (26.2%) and thyroid disorders (6.7%). Deforming RA was present in 33.3% of patients, and hip involvement was observed in 23.3%. The mean fatigue VAS score was 7 ± 1.6, and the mean HAQ score was 1.07 ± 0.43.
Regarding disease activity, 33.3% of patients were in remission, 43.4% had moderate disease activity, and 23.3% had high disease activity. Corticosteroids were prescribed in 91.5% of patients. The most frequently used disease-modifying antirheumatic drugs were methotrexate (66.7%) and biologic therapies (70.3%).
All patients reported a decrease in sexual desire since disease onset, mainly related to pain, physical limitations, fatigue, and psychological distress. The mean FSFI score was 23.6, indicating a high prevalence of sexual dysfunction. Overall, 63.3% of patients reported a negative impact of RA on their sexual activity. Statistical analysis demonstrated a significant association between sexual dysfunction and fatigue ($p = 0.03$), higher disease activity ($p = 0.05$), and greater functional disability, as reflected by higher HAQ scores ($p = 0.01$). No significant association was found between sexual dysfunction and patient age ($p = 0.2$).
Conclusion:
This study demonstrates a high prevalence of sexual dysfunction among women with rheumatoid arthritis, significantly associated with fatigue, disease activity, and functional impairment. These findings highlight the importance of systematically assessing sexual health as an integral component of comprehensive RA management. Addressing sexual dysfunction may contribute to improving overall quality of life and patient-centered care outcomes.

P380

SEASONAL CLIMATIC VARIABILITY AND ITS CLINICAL IMPACT ON DISEASE ACTIVITY IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES

C. H. Knani[1], R. Fakhfakh[1], D. Khalifa[1], N. El Amri[1], H. Hachfi[1], K. Baccouche[1], I. Bouagina[1]

[1]Farhat Hached hospital, Sousse, Sousse, Tunisia

Introduction:
Climate change has led to increasing variability in environmental conditions, including temperature, humidity, and other climatic factors, which may potentially influence the activity of chronic inflammatory diseases. Determining whether these climatic variations have a measurable impact on disease activity is essential to improve patient management. This study aimed to evaluate the impact of seasonal climatic variability on disease activity in patients with chronic inflammatory rheumatic diseases.
Patients and Methods:
We conducted a retrospective cross-sectional study in the rheumatology department including 30 patients diagnosed with chronic inflammatory rheumatic diseases. Patients were interviewed regarding seasonal variations in their symptoms. Disease activity was assessed using the Disease Activity Score in 28 joints (DAS28) for rheumatoid arthritis (RA) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for ankylosing spondylitis (AS). Subjective patient-reported outcomes were compared with objective disease activity scores to assess potential seasonal associations.
Results:
Thirty patients were included, with a mean age of 49.43 ± 12.33 years. There was a female predominance, with a male-to-female ratio of 0.5. Regarding educational level, 20% had higher education, 30% secondary education, 13.3% primary education, and 36.7% were illiterate. More than half of the patients (53.3%) were unemployed. Urban residence was reported in 53.3% of patients, while 46.7% lived in rural areas. Rheumatoid arthritis was present in 73.3% of patients and ankylosing spondylitis in 26.7%.
Overall, 73.3% of patients (n=22) reported a perceived impact of climatic changes on disease activity, including 15 patients with RA and 7 with AS. Symptom worsening was most frequently reported during summer (40%), followed by winter (30%). In response to symptom exacerbation, 16 patients reported self-medication, while 6 sought medical consultation.
DAS28 scores were higher during periods of elevated temperatures, with 70% of RA patients presenting a DAS28 score >3.5. Similarly, patients with AS reported increased symptom severity during summer, with 71.4% reporting symptom exacerbation and a mean BASDAI score of 2.1. However, univariate analysis showed that climatic variation was not significantly associated with objective worsening of disease activity scores ($p > 0.01$).
Conclusion:
Although most patients reported subjective worsening of symptoms associated with seasonal climatic variability, objective disease activity measures, including DAS28 and BASDAI, did not demonstrate significant associations. These findings highlight the discrepancy between patient perception and objective disease activity and underscore the need for larger prospective studies to better understand the impact of climatic factors on chronic inflammatory rheumatic diseases and to optimize patient management strategies.

P381

REAL-WORLD PREDICTORS OF BIOLOGIC THERAPY RESPONSE IN RHEUMATOID ARTHRITIS: FOCUS ON COMORBIDITIES AND BIOMARKERS

C. H. Knani[1], R. Grassa[1], M. Ghali[1], N. Ben Chekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Monastir, Monastir, Tunisia

Introduction: The management of rheumatoid arthritis (RA) has been substantially improved by the introduction of biologic disease-modifying antirheumatic drugs. However, therapeutic response remains variable, highlighting the need for a more individualized approach to treatment. The identification of clinical, biological, and comorbidity-related predictors of response represents a key step toward optimizing therapeutic decisions and improving outcomes, particularly in real-world and resource-constrained settings. This study aimed to identify independent predictors of clinical response to biologic therapies at 6 months in patients with RA managed in routine rheumatology practice.
Methods: We conducted a cross-sectional study including 118 patients with rheumatoid arthritis (RA) fulfilling the 2010 ACR/EULAR classification criteria, all treated with biologic DMARDs for at least 6 months. Demographic data (age, sex, BMI), clinical characteristics (disease duration, DAS28, presence of erosions), biological markers (CRP, rheumatoid factor, anti-CCP antibodies), ongoing treatments (conventional DMARDs, biologic DMARDs, corticosteroids), and cardiovascular comorbidities (hypertension, diabetes, dyslipidemia, obesity, smoking) were systematically recorded. Multivariate analyses were performed to identify factors independently associated with clinical response to biologic therapy at 6 months.
Results: A total of 118 patients with rheumatoid arthritis (RA) were included, comprising 99 women and 19 men (female-to-male ratio = 0.19). The mean age was 56.9 ± 11.6 years (range: 28–81), with a mean disease duration of 12.1 ± 5.5 years (2–23). The most frequently observed comorbidities were diabetes mellitus (34.7%), arterial hypertension (33.1%), and dyslipidaemia (11.9%). The mean body mass index was 29.2 ± 5.1 kg/m² (range: 18.9–49.3).
Overall, disease activity was high, with a mean DAS28 score of 5.66 ± 1.09 (range: 2.93–7.93) and a mean C-reactive protein level of 29.3 mg/L (range: 0–154). Mean pain intensity assessed by the visual analogue scale was 52.5 ± 20.3 mm, and functional disability, evaluated using the Health Assessment Questionnaire (HAQ), averaged 1.66 ± 0.85 (range: 0.12–2.87). Rheumatoid arthritis was seropositive in 71.8% of patients and erosive in 94.1%.
Regarding treatment, 83.9% of patients were receiving conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), and 99.2% were on oral corticosteroid therapy. At six months of follow-up, 60.1% of patients achieved a good therapeutic response to biologic agents.
In multivariate analysis, anti–citrullinated protein antibody (ACPA) positivity ($p = 0.001$) and early initiation of biologic therapy (≤ 1 year) ($p < 0.001$) were identified as independent predictors of a favourable therapeutic response. Conversely, elevated C-reactive protein levels ($p < 0.001$) and the presence of diabetes mellitus ($p = 0.003$) were significantly associated with a poorer response to biologic treatments.
Conclusion: In this cohort of RA patients, early initiation of biologic therapy and positive response for anti-CCP antibodies were independent predictors of a favorable clinical response at 6 months. Conversely, elevated baseline CRP levels and the presence of diabetes were

associated with reduced therapeutic efficacy. These findings underscore the importance of integrating both biological markers and comorbidities into treatment decision-making, to optimize personalized management strategies and improve outcomes in RA patients receiving biologic therapies.

P382

EFFECTS OF INTEGRATED INTERVENTION ON BONE MINERAL DENSITY AND CLINICAL SYMPTOMS IN PATIENTS WITH OSTEOPOROSIS

C. H. Liang[1], X. R. Li[2], H. C. Hsieh[2]

[1]Department of Orthopedics, Tungs' Taichung MetroHarbor Hospital, Taiwan, Taichung, Taiwan; [2]Department of Nursing, Tungs' Taichung MetroHarbor Hospital, Taiwan, Taichung, Taiwan

Objective: Osteoporosis is a primary disease leading to fractures, chronic low back pain, and impaired physical mobility. When bone mineral density (BMD) falls significantly below the normal range, patients suffer not only from persistent pain but also from a substantially increased risk of fractures. With the advancement of osteoanabolic therapies, concurrent nutritional supplementation and resistance training can further enhance bone mass accrual and symptom relief. This study presents the specific outcomes in bone density improvement and pain reduction of two very-high-risk osteoporotic patients who underwent osteoanabolic treatment integrated with nutritional counseling and resistance exercise guidance provided by health educators.

Materials and Methods: This study is presented as a case report involving two very-high-risk osteoporotic patients. Both subjects received consistent osteoanabolic therapy. During the treatment period, a professional health educator provided nutritional counseling—including recommendations for calcium, vitamin D, and protein intake—and designed individualized resistance exercise programs, such as resistance band training, simple weight-bearing exercises, and core stability exercises. Clinical outcomes were assessed using the Numerical Rating Scale (NRS) for low back pain and bone mineral density (BMD) scans before and after treatment. Follow-up BMD scans were conducted two years post-treatment, specifically measuring changes in the lumbar spine T-score to compare the magnitude of improvement.

Results: This study is presented as a case report involving two very-high-risk osteoporotic patients. Both subjects received consistent osteoanabolic therapy. During the treatment period, a professional health educator provided nutritional counseling—including recommendations for calcium, vitamin D, and protein intake—and designed individualized resistance exercise programs, such as resistance band training, simple weight-bearing exercises, and core stability exercises. Clinical outcomes were assessed using the Numerical Rating Scale (NRS) for low back pain and bone mineral density (BMD) scans before and after treatment. Follow-up BMD scans were conducted two years post-treatment, specifically measuring changes in the lumbar spine T-score to compare the magnitude of improvement.

Conclusion: Integrating nutritional counseling and resistance exercise into an osteoanabolic treatment regimen yields comprehensive benefits for very-high-risk osteoporotic patients. Both patients in this study demonstrated significant increases in bone mineral density (BMD) and substantial pain relief. These outcomes suggest that this combined therapeutic strategy not only promotes bone reconstruction but also enhances muscle strength and stability, leading to a marked improvement in the patients' quality of life. The findings support the clinical feasibility and efficacy of coupling osteoanabolic therapy with lifestyle interventions. Future large-scale, long-term studies are warranted to confirm the sustainability of these therapeutic effects.

P383

THE STATUS OF CARE FOR MALE OSTEOPOROSIS IN HUNGARY – INSIGHTS BASED ON THE EXPERIENCE OF A DENSITOMETRY LABORATORY

C. Horvath[1], T. Leel-Össy[1], Z. Farkas[1], A. May[1], E. Hosszu[2], E. Csupor[3], S. Meszaros[1]

[1]Department of Internal Medicine and Oncology, Semmelweis University, Budapest, Hungary; [2]Department of Pediatrics, Semmelweis University, Budapest, Hungary; [3]Buda Endocrine Center, Budapest, Hungary

Osteoporosis affects both sexes but becomes prevalent at a later age in men. After 70 years, hip fracture incidence is similar in men and women, while post-fracture mortality is higher in men. Despite this, men receive anti-osteoporotic care less frequently.

Objective: Patients from all regions of Hungary are referred to our laboratory for bone densitometry. We assessed the frequency of bone density testing in men compared with women and their osteological status at presentation.

Materials and Methods: We analyzed densitometry measurements performed between 2019 and 2023 using a Lunar Prodigy device. Bone mineral density (BMD) was measured at the lumbar spine, femoral neck, total hip, and proximal radius. Prior low-trauma fractures, FRAX risk factors and fracture probability, and treatment status were recorded. Each male patient was matched with a female control based on age, BMI, and femoral neck T-score.

Results: Over five years, 12,205 patients were examined; 915 (7.5%) were men, 60% older than 60 years. The proportion of men remained unchanged. Prior fractures occurred in 222 men (24%), 77% in those over 60 years (prevalence 31%). Based on femoral T-scores, 30% had normal bone mass, 49% osteopenia, and 21% osteoporosis; prior fractures were present in 17%, 22%, and 41% of men versus 9%, 40%, and 46% of female controls. FRAX-HIP was 5.3% in osteoporotic men and normal in other groups, while in female controls it reached 3.1% in osteopenia and 7.3% in osteoporosis. Smoking, parental fracture, secondary osteoporosis, and glucocorticoid therapy were the most frequent risk factors. Only 34 men (3.7%) received anti-osteoporotic treatment. Seventy-nine osteoporotic men were re-evaluated after a mean of 2.5 years; treatment rates increased from 15% to 32%.

Conclusion: Above 70 years of age, fracture incidence is similar in men and women and represents the third leading cause of mortality. Nevertheless, male osteoporosis remains severely underdiagnosed and undertreated, contributing substantially to the increasing burden of low-trauma fractures.

P384

COMPARISON OF URINARY TRACT INFECTION IN ELDERLY HIP FRACTURE PATIENTS: EARLY VERSUS DELAYED INSERTION OF URINARY CATHETERS

C. Jaruwan[1]

[1]Department of Orthopedic Surgery, Ratchaphiphat Hospital, Bangkok Metropolitan Administration, Bangkok, Thailand

Objective: To compare urinary tract infection (UTI) in elderly hip fracture patients between early and delayed urinary catheterization.
Material and Methods: A retrospective chart review was conducted in hip fracture patients aged ≥60 years between January 2018 and December 2022. A total of 199 patients met the inclusion criteria: 70 in the early catheterization group (catheter inserted upon admission) and 129 in the delayed catheterization group (catheter inserted when unable to void). UTI was defined using CDC criteria. Primary outcome was UTI; secondary outcomes were length of hospital stay (LOS) and mortality. Multivariable regression analysis was performed to adjust for catheter duration.
Results: UTI incidence was significantly higher in the early catheterization group than in the delayed group (22.9% vs 10.9%, p=0.024). Catheter duration was longer in the early group (9.5±3.6 vs 4.1±3.1 days, p<0.001). LOS and mortality were not significantly different on univariate analysis. After adjustment for catheter duration, the difference in UTI was no longer statistically significant (adjusted OR 1.06, 95% CI 0.35–3.15), while LOS remained significantly longer in the early catheterization group.
Conclusion: Although early urinary catheterization was associated with higher UTI incidence, this association disappeared after adjusting for catheter duration, suggesting that prolonged catheter use—not timing of insertion—is the key driver of UTI risk. Delaying catheterization when feasible and minimizing catheter duration may reduce UTI risk and shorten hospitalization in elderly hip fracture patients.

RISK FACTORS FOR LOW-ENERGY DISTAL RADIUS FRACTURE IN OLDER ADULTS FOLLOWING MINOR FALLS: A RETROSPECTIVE STUDY

C. Jaruwan[1], P. Sitthisen[1], W. Eaimjinnasuwat[2], T. Jongjaid[3], T. Harnroongroj[4]

[1]Department of Orthopedic Surgery, Ratchaphiphat Hospital, Bangkok Metropolitan Administration, Bangkok, Thailand; [2]Department of Geriatric Medicine, Ratchaphiphat Hospital, Bangkok Metropolitan Administration, Bangkok, Thailand; [3]Department of Community Medicine, Ratchaphiphat Hospital, Bangkok Metropolitan Administration, Bangkok, Thailand; [4]Department of Orthopedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objective: To identify risk and protective factors associated with low-energy distal radius fracture in older adults following minor falls.

Material and Methods: We conducted a retrospective study of adults aged ≥60 years presenting after minor falls between January 1, 2018 and December 31, 2022. Patients were classified into a distal radius fracture group and a no-fracture group. Demographic characteristics and potential risk/protective factors, including clinical and lifestyle variables, were collected from medical records. Univariable and multivariable logistic regression analyses were performed to identify independent associations.

Results: 80 patients met the inclusion criteria (60 with distal radius fractures and 20 without fractures). Female sex was associated with higher fracture risk (OR 4.17–4.71; 95% CI 1.25–17.72; p=0.022). Calcium and vitamin D intake were protective (calcium: OR 0.06, 95% CI 0.01–0.34, p=0.001; vitamin D: OR 0.03, 95% CI 0.00–0.28, p=0.002). After adjustment for sex, calcium and vitamin D intake remained independently protective (adjusted OR 0.05, 95% CI 0.01–0.28; adjusted OR 0.02, 95% CI 0.00–0.22, respectively).

Conclusion: In older adults sustaining minor falls, female sex was associated with increased risk of low-energy distal radius fracture, while calcium and vitamin D intake were independently protective. These findings support fracture-prevention strategies in older adults that emphasize adequate calcium and vitamin D intake, particularly among higher-risk groups.

Acknowledgments: This study received funding support from the Medical Council of Thailand (Police General Dr. Jongjate Aojanepong Foundation).

Disclosures: The authors declare no conflict of interest.

FRACTURES AND BONE MINERAL DENSITY LOSS IN ADULTS LIVING WITH HIV IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. L. Gregson[1], M. Westby[2], A. De Wilton[1], T. Madanhire[3], J. Savovic[2], G. Gwaze[4], M. Vitoria[5], J. Amuthavalli Thiyagarajan[5], K. A. Ward[6]

[1]Global Health and Ageing Research Unit, University of Bristol, Bristol, United Kingdom; [2]Population Health Sciences, University of Bristol, Bristol, United Kingdom; [3]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom; [4]The Health Research Unit, Biomedical Research and Training Institute, Harare, Zimbabwe; [5]The World Health Organization, Geneva, Switzerland; [6]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective
To synthesise low- and middle-income country (LMIC) evidence on fractures and bone mineral density (BMD) loss, including associations with antiretroviral therapy (ART) and pre-exposure prophylaxis (PrEP) and fracture/BMD risk factors, in adult people living with HIV (PLHIV) or using PrEP.
Methods
We searched Embase, Medline, SciElo, WHO Global Index Medicus for evidence on fractures and BMD in PLHIV in LMICs. Analysis included meta-analysis, network meta-analysis (NMA) and component NMA. We

examined heterogeneity with subgroup analysis and meta-regression. 38 studies were included. PROSPERO: CRD42024587101

Results

Pooled fracture prevalence was 10% [95%CI 5, 16%] (self-reported/vertebral imaging) (n=20 studies), 19% [11, 30%] in PLHIV for >5 years, and 25% [14, 39%] with vertebral imaging. HIV is associated with prevalent fracture OR 2.1 [1.2, 3.6] (n=2 studies). In longitudinal DXA studies PLHIV have greater BMD loss than HIV-negative adults, varying with type of ART: over 1-year TDF-ART is associated with 3.5% [3.0, 4.1] more BMD loss (4 studies; n=577) than HIV negative groups. In PLHIV, fracture risk factor analyses for traditional risk factors were sparse and imprecise (few fractures). Lower BMI and smoking were most consistently associated with future BMD loss. TDF ART vs non-TDF ART may be associated with prevalent fracture (pooled OR 1.7, [0.72, 4.1]). For PrEP, NMA of 7 RCTs (21,236 people) suggests TDF monotherapy vs placebo may increase fracture risk (RR 1.3 [0.97, 1.7], but GRADE low certainty evidence). However, TDF PrEP (vs placebo) is associated with greater BMD loss, more so in those adhering to PrEP (BMD difference −1.2% [−1.6, −0.81]). In PLHIV, RCT evidence shows lower BMD for TDF vs non-TDF ART. No study investigated fracture prevention. Two small pilot studies showed possible benefits of exercise on BMD. Two studies concluded FRAX assessment may underestimate fracture risk in PLHIV.

Conclusion

Fractures are frequent in adult PLHIV in LMICs. Exposure to TDF and smoking accelerate bone loss and may increase fracture risk, with TDF-related BMD declines like those seen in menopause. Other risk factors are understudied, and research mainly involves adults <50yrs. Existing risk assessment tools may underestimate fracture risk in adult PLHIV, and significant evidence gaps remain.

P387

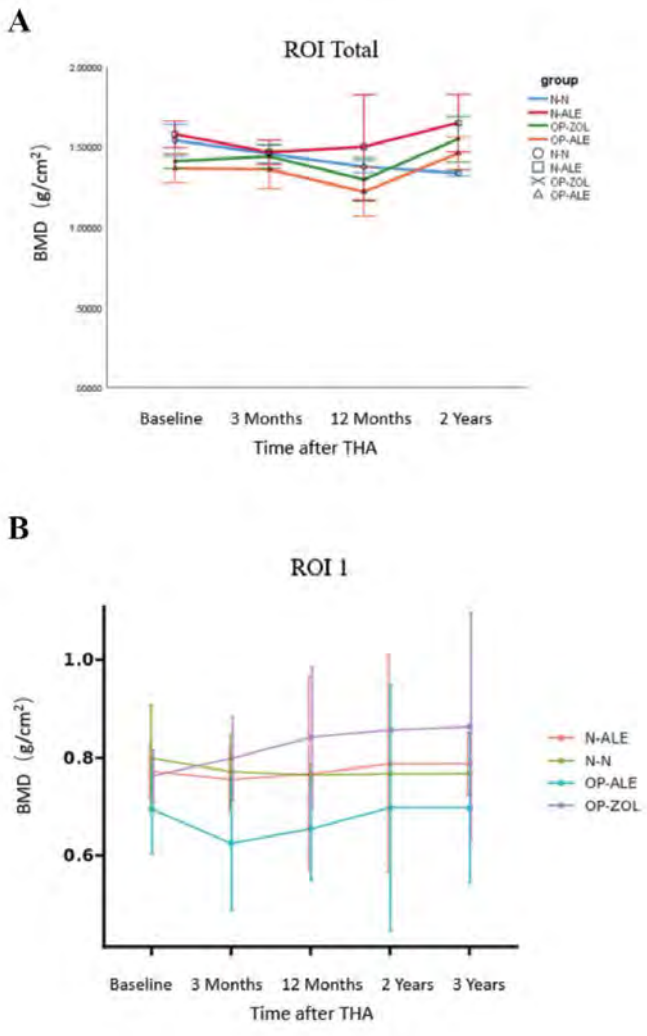
EFFECTS OF BISPHOSPHONATES ON PERIPROSTHETIC BONE LOSS AFTER TOTAL HIP ARTHROPLASTY

C. Li[1], W. C. Ko[1], Y. Ding[1]

[1]Department of Orthopaedic Surgery, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Objective: Periprosthetic bone loss is a major cause of implant loosening after total hip arthroplasty (THA). Bisphosphonates may mitigate postoperative loss, but comparative effects remain unclear. This study aims to assess the effect of alendronate in patients with normal preoperative bone mass undergoing THA and to compare zoledronic acid with alendronate in osteoporotic patients.

Material and Methods: In this prospective randomized study, adults undergoing primary THA were allocated according to baseline bone status. Normal BMD (bone mineral density) patients received either no specific postoperative treatment (control) or alendronate (calcium-vitamin D 600 mg/day plus alendronate-vitamin D 70 mg/week). Osteoporotic patients received zoledronic acid (calcium-vitamin D 600 mg/day, calcitriol 0.25 μg/day, and zoledronic acid 5 mg annually) or alendronate (calcium-vitamin D 600 mg/day, calcitriol 0.25 μg/day, and alendronate-vitamin D 70 mg/week). BMD of seven Gruen zones, spine, and hip was measured at day 7, month 3, month 12, and annually. Ethical approval and informed consent were obtained.



Results: A total of 202 patients were included (normal BMD control 42; normal BMD + alendronate 42; osteoporosis + zoledronic acid 62; osteoporosis + alendronate 56). In normal BMD patients, controls showed decreased total Gruen-zone BMD at 3 months (−4.82%, p = 0.013) and remained below baseline at years 2–3 (−5.23%, −5.10%). The alendronate group showed a smaller early decrease, and significant increases above baseline at 2 years (+4.47%, p = 0.048) and 3 years (+4.52%, p = 0.047). Among osteoporotic patients, alendronate caused approximately 5% BMD loss at 3 months, most prominent in zone 1 (−9.25%). Zoledronic acid produced consistent zone-1 BMD gains at years 1–3 (+11.40%, p = 0.018; +12.23%, p = 0.013; +12.83%, p = 0.038), significantly exceeding alendronate, except at 3 months (+4.74%, p = 0.089).

Conclusions: Alendronate preserves periprosthetic BMD in normal BMD patients after THA, whereas zoledronic acid provides superior protection in osteoporotic patients.

THE USE OF TRASPEDICULAR SCREWS IN THORACIC SPINE AFTER TRAUMA

C. M. Matzaroglou[1], J. G. Gliatis[1], C. K. Koutserimpas[1], M. T. Tsekoura[1], E. B. Billis[1], K. K. Kafchitsas[1]

[1]School of Health Sciences, Department of Physiotherpy and Department of Orthopedics, University of Patras, Patras, Greece

PURPOSE OF THE STUDY: The evaluation and adaptation of the surgical technique through the prism of the gold screws in the neck of the fractured vertebra. Correlation with the torque of the screws in the adjacent levels.

MATERIAL AND METHODS: During 42 consecutive surgeries after a fracture in the thoracolumbar spine (fractured vertebra O1 or T12) the torque of all screws was measured. A specially designed instrument was used for the measurements, which can also be used intraoperatively and covers the range of measurable torque. Statistical correlation of the parameters followed (Sigma Plot).

RESULTS: The maximum value of the torque was in the fractured vertebra 1.7 Nm and the minimum 0.346 Nm. The maximum value of the torque was in the normal vertebrae 1.23 Nm and the minimum 0.108 Nm. The torque was statistically significantly different ($p<0.05$) and greater than the torque in the normal vertebrae.

CONCLUSIONS: Transcervical screws are used for stabilization in the vertebral body. Based on the conclusions of this study and previous ones made by the same group, we connect the biomechanical behavior of transcervical screws with the torque. We also connect the answer to the question of whether cement reinforcement is required in osteoporotic vertebrae or not. Based on the results of this study, the use of a transcervical screw in the fractured vertebra is necessary for the spinal fusion to gain stability. In further studies, it may be shown and ultimately proven that in this way the length of the spinal fusion can be reduced.

A HOME-BASED ONLINE EXERCISE PILATES PROGRAM IN PATIENTS WITH DEGENERATIVE SCOLIOSIS

C. M. Matzaroglou[1], E. B. Billis[1], K. K. Kafchitsas[1], M. T. Tsekoura[1], C. K. Koutserimpas[1], S. L. Lampropoulou[1]

[1]School of Health Sciences, Department of Physiotherpy and Department of Orthopedics, University of Patras, Patras, Greece

Introduction: The importance of the spine for human movement and for the proper functioning of all structural units of the body is immense. A very common condition for the spine is degenerative scoliosis. Researchers are still testing various methods, within the framework of physiotherapy exercise, in their attempt to halt the progression of scoliosis or even reverse it. One of the newest methods, which is under investigation for its effectiveness, is that of Pilates.

Patients and Methods: A single prospective cohort design was used involving 45 patients (54 – 82 years old - 32 female and 13 male), with Cobb angle (15°-42°). Participants engaged in supervised online Schroth-Pilates sessions (Picture-1) two times per week for two months. Primary measures included Cobb angle, ODI (Oswestry Disability Index) and HADS (Hospital Anxiety and Depression Scale) recorded at baseline and post-program.

Results: The overall program completion rate was 82.4%, with no significant adherence differences between age groups and sex. The primary outcome of the parent study was ≥ 30% improvement in Oswestry Disability Index (ODI), 10% improvement in HADS at 8 weeks, and significant improvements were observed in Cobb angle [$F(1,08) = 12.42$, $p < .001$, $\eta^2 = .245$]

Conclusions: A home-based Schroth-Pilates program is a clinically effective method in patients with degenerative scoliosis, achieving high adherence and meaningful improvements in pain and spine functionality. These results support the clinical viability of Pilates program in scoliosis rehabilitation and highlight the need for future controlled and longitudinal studies to confirm the long-term outcomes.

IMPACT OF A SECONDARY FRAGILITY FRACTURE PREVENTION PROGRAM IN AN ORTHOGERIATRIC CARE CENTER (2014–2024)

A. M. Lopez[1], C. Rojas[1], J. F. Perdomo[1], C. M. Olarte[1], V. Canedo[1], R. F. Pesantez[1], A. Patiño[1], V. Sanint[1], J. E. Salavarrieta[1], D. Morales[1], M. X. Meneses[1]

[1]Fundacion Santa Fe de Bogota, Bogota, Colombia

Objectives: Fragility fractures, particularly hip fractures, are associated with increased mortality, disability, and reduced quality of life, with a high risk of subsequent fractures in the early post-fracture period. The objective of this study is to evaluate the impact of a Secondary Fragility Fracture Prevention Program in an Orthogeriatric Center, characterizing its implementation in patients aged 65 years and older and analyzing adherence to osteoporosis treatment and its effect on the reduction of new fragility fractures.

Material and Methods: A retrospective descriptive cohort study was conducted including patients aged ≥65 years with fragility hip fractures managed at an Orthogeriatric Clinical Care Center between 2014 and 2024. Only patients with completed follow-up were included.

Results: A total of 701 patients were analyzed, with a mean age of 83 years. Over time, the program was associated with substantial improvements in secondary fracture prevention indicators. While no patients received osteoporosis treatment indication in 2014, treatment rates increased to 88.7%, 87.0% and 66.0% in 2022, 2023 and 2024, respectively. Densitometry at discharge increased markedly, reaching over 90% in 2022 and remaining high thereafter. The incidence of falls during the first postoperative year decreased to below 10% in recent years. Refracture rates remained relatively low (11.6%, 5.6% and 9.1% in 2022–2024). Lower vitamin D levels at admission were significantly associated with refracture occurrence ($p < 0.05$).

Conclusion: The orthogeriatric secondary fracture prevention program demonstrated a sustained positive impact on osteoporosis management, reducing falls and maintaining low refracture rates over a ten-year period. The association between low vitamin D levels and refracture underscores the importance of metabolic optimization within comprehensive secondary prevention strategies.

Disclosures: The authors declare no conflicts of interest.

COST–CONSEQUENCE ANALYSIS IN GERIATRIC PATIENTS WITH FRAGILITY HIP FRACTURES TREATED BETWEEN 2018 AND 2022 AT FUNDACIÓN SANTA FE DE BOGOTÁ, COLOMBIA

C. M. Olarte[1], A. M. Lopez[2], J. F. Perdomo[1], C. Rojas[1], D. Morales[2], V. Sanint[2], A. Patiño[2], D. Londoño[3], K. K. Rojas[3], J. D. Bernate[1], A. Solano[1]

[1]Orthopedics Department, Fundación Santa Fe de Bogotá University Hospital, Bogota, Colombia; [2]Geriatrics Department, Fundación Santa Fe de Bogotá University Hospital, Bogota, Colombia; [3]Division of Clinical and Epidemiological Studies, Fundación Santa Fe de Bogotá, Bogota, Colombia

Objective: The global population, including Colombia, is aging, which increases the risk of hip fragility fractures due to loss of muscle mass, mobility limitations, and comorbidities. It is estimated that 1 in 3 women and 1 in 5 men over the age of 50 will experience this type of fracture. In Latin America, their management involves direct costs ranging from 4,500 to 6,000 USD. Therefore, the present study aims to determine, through an economic evaluation, the potential cost savings associated with the management of fragility hip fracture fixation compared with an international comparator.

Materials and Methods: A cost–consequence study was conducted in patients aged 65 years or older with hip fractures, treated with osteosynthesis or arthroplasty between 2018 and 2022 within a specialized orthogeriatric program. The results were compared with the 2022 Spanish National Hip Fracture Registry and with international literature.

Results: The average cost per procedure in Spain ranged from 9,231.9 to 10,723.9 USD, while in Colombia it ranged from 1,717.8 to 2,742.0 USD. Compared to the international reference, better clinical outcomes were observed: lower incidence of delirium (-3.4 days), a higher proportion of timely surgeries (+39.2%), reduced length of stay (-3.92 days), and a lower surgical site infection rate (-6). Readmissions were slightly higher (+1.06%). A monthly savings of 3,235.23 USD per patient was identified. If 40% of the city's procedures were performed under this model, the estimated annual savings would be 21,399,105.31 USD.

Conclusion: The implementation of an organized model based on early surgery and a multidisciplinary approach improves clinical outcomes and reduces the costs associated with the treatment of these fractures.

Disclosures: The authors declare no conflicts of interest.

POPULATION-BASED STUDY OF FUNCTIONAL ABILITY AND SARCOPENIA PREVALENCE IN AFRICA: DEVELOPING CONTEXT APPROPRIATE THRESHOLDS (AFRO-SARC)

C. M. Pearse[1], A. Manyara[2], L. Micklesfield[3], E. I. Y. Madela[4], E. De Lucia Rolfe[1], A. J. Burton[2], H. Wilson[2], I. Drammeh[5], L. S. Gates[1], C. Grundy[6], B. Cassim[4], R. A. Ferrand[7], C. L. Gregson[2], K. A. Ward[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Global Health and Ageing Research Unit, University of Bristol, Bristol, United Kingdom; [3]Univeristy of the Witwatersrand, Johannesburg, South Africa; [4]Department of Geriatrics, University of KwaZulu-Natal, Durban, South Africa; [5]MRC Unit The Gambia, Fajara, Gambia; [6]London School of Hygiene and Tropical Medicine, London, United Kingdom; [7]Biomedical Research and Training Institute, Harare, Zimbabwe

Objective: To establish African-specific thresholds for physical function and sarcopenia (AFRO-SARC) and to describe the prevalence of impaired function and sarcopenia across three African populations.
Methods: A population-based sample of adults aged ≥40 years, stratified by sex- and age-band, was recruited using GIS mapping in The Gambia (G), Zimbabwe (Z) and South Africa (SA). Grip strength, gait speed, and chair rise times (CRT) were measured. Harmonised African thresholds were derived using 40-49 years as a reference population, taking 2SD below the mean (grip and gait) or 10th centile (CRT) to define thresholds; interclass correlations assessed country-pooling feasibility. The prevalence of sarcopenia, defined as low grip strength plus slow walk speed, was calculated.
Results: AFRO-SARC thresholds, calculated in 4776 adults (2537[53%] women) were: **grip strength** <28 kg (men) and <18 kg (women); **gait speed** <0.6 m/s (men and women), and **CRT** >17 s (men) and >19 s (women). Prevalence of impaired function was: **grip strength** men: 11.4% (G), 20.7% (SA), 10.4% (Z), women: 13.3% (G), 24.4% (SA), 8.1% (Z); **gait speed** men: 5.2% (G), 5.9% (SA), 6.1% (Z), women: 12.4% (G), 12.6% (SA), 14.0% (Z); **CRT** men: 18.9% (G), 24.2% (Z), women: 16.9% (G), 22.3% (Z). Sarcopenia prevalence overall was 2.3% in men and 3.7% in women (figure), and was greatest in those aged ≥70 years, affecting 7.3% men and 9.1% women. Individuals with showed markedly poorer functional performance, with over 80% scoring below 8 on the SPPB across age groups and had higher prevalence of disability and multimorbidity.
Conclusions: This study provides the first harmonised African thresholds defining poor physical performance and sarcopenia. Findings support context-specific screening strategies by which to target interventions to reduce disability and improve ageing in resource-limited settings.

ANTI-OSTEOPOROTIC TREATMENT EFFICACY IN PATIENTS WITH SPONDYLOARTHROPATHIES – DESCRIPTION OF A TERTIARY CENTER EXPERIENCE

C. Martins[1], H. Cecílio[1], S. Chaves[1], I. T. Pereira[2], A. R. Cruz-Machado[1], A. Silva[1]

[1]Rheumatology Department, Unidade Local de Saúde Santa Maria, Centro Académico de Medicina de Lisboa, Lisbon, Portugal; [2]Unidade de Saúde Familiar Venda Nova, Unidade Local de Saúde Amadora/Sintra, Lisbon, Portugal

Introduction: Spondyloarthropathies are a major group of inflammatory rheumatic diseases affecting the axial skeleton and peripheral joints, with spondyloarthritis (SpA) and psoriatic arthritis (PsA) as the most prevalent subtypes. These conditions are recognized risk factors for osteoporosis (OP); however, data on the impact and effectiveness of anti-osteoporotic therapy in these patients remains limited.
Objective: To evaluate the efficiency of anti-OP therapy in patients with PsA/SpA.
Material and Methods: All consecutive patients attending our outpatient clinic over a 3-month period (September to November 2025) with a concomitant diagnosis of SpA or PsA and OP were included. Patients were matched in a 1:2 ratio by age and sex with individuals diagnosed with primary OP. Patients with known secondary causes of OP were excluded. Inclusion criteria required the availability of at least two dual-energy X-ray absorptiometry assessments.
Results: Forty-seven patients with SpA/PsA and concomitant OP (80.9% female) were compared with 83 patients with primary OP (91.6% female). No significant differences were observed in sex, age at OP diagnosis, current age, or use of medications related to secondary OP except for glucocorticoids (p=0.001) [Figure 1].
At baseline, the SpA/PsA group had higher bone mineral density (BMD) at the femoral neck (FN; p=0.035) and lumbar spine (LS; p=0.022), higher C-reactive protein (CRP) levels (p=0.006), and lower bone turnover markers (P1NP, p=0.035; B-CTx, p=0.037).
Following anti-osteoporotic treatment, BMD remained significantly higher in the SpA/PsA group at the FN (0.602±0.101 vs 0.582±0.094 g/cm², p=0.002), total femur (0.739±0.108 vs 0.715±0.095 g/cm², p=0.001), and LS (0.802±0.136 vs 0.773±0.117 g/cm², p=0.003). CRP levels remained higher (0.61±0.86 vs 0.27±0.31 mg/dL, p=0.006), while P1NP (13.10±5.20 vs 51.90±35.60 ng/mL, p=0.035), B-CTx (0.09±0.04 vs 0.38±0.37 ng/mL, p=0.037), and vitamin D levels (29.70±12.80 vs 38.60±15.10 IU, p=0.001) were lower.
Fracture incidence did not differ between groups. In fully adjusted multivariate analyses accounting for OP treatment characteristics, smoking status, and fracture burden, no significant between-group differences were observed.
Conclusions: In our cohort, anti-osteoporotic treatment in patients with SpA/PsA and concomitant OP demonstrated comparable effectiveness to that observed in patients with primary OP, with no differences in fracture incidence. These findings warrant confirmation in larger, well-powered cohorts.

BILATERAL FEMORAL SHAFT FRACTURES ASSOCIATED WITH LONG-TERM BISPHOSPHONATE THERAPY

S. Naoum[1], S. Nahas[1], J. Duncan[1], K. Kaliarntas[2], M. Tsekoura[2], S. Lampropoulou[2], C. Matzaroglou[2], C. Koutserimpas[2]

[1]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [2]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece

Objective:
To report the clinical course, imaging findings, and management of bilateral atypical femoral fractures (AFFs) in a postmenopausal woman receiving long-term bisphosphonate therapy, emphasizing early recognition and multidisciplinary management.

Material and Methods:
A 64-year-old female with severe osteoporosis on oral alendronate for 3.5 years presented with insidious bilateral thigh pain. MRI demonstrated bilateral mid-diaphyseal stress changes with lateral cortical thickening, endosteal sclerosis, marrow oedema, and periosteal reaction, consistent with incomplete AFFs. Despite offloading, she sustained an acute right femoral shaft fracture following a low-energy fall. Radiographs confirmed a displaced transverse fracture with lateral cortical "beaking."

Surgical management included open reduction, valgisation osteotomy, intramedullary nailing, and lateral plate fixation. Postoperative care included cessation of bisphosphonate therapy, initiation of teriparatide, calcium and vitamin D supplementation, and monitoring of the contralateral femur for prophylactic fixation.

Results:
The right femur achieved stable fixation and satisfactory alignment, permitting early mobilization. Contralateral femoral surveillance identified an incomplete AFF, with prophylactic nailing planned. Metabolic bone evaluation guided long-term osteoporosis management and transition from bisphosphonate therapy.

Conclusion:
AFFs are rare but serious complications of long-term bisphosphonate therapy, often preceded by prodromal thigh pain and stress-related cortical changes detectable on MRI. Early recognition, surgical stabilization of complete fractures, prophylactic management of incomplete fractures, and tailored pharmacological therapy, including anabolic agents, are essential to optimize outcomes and prevent bilateral injury.

ROBOTIC ARM-ASSISTED TOTAL HIP ARTHROPLASTY PERFORMS EXCELLENTLY AT A MINIMUM OF 3 YEARS FOLLOW-UP

K. Dretakis[1], S. Naoum[2], C. Matzaroglou[3], K. Kaliarntas[3], M. Piagkou[4], E. Billis[5], C. Koutserimpas[3]

[1]Second Department of Orthopaedic Surgery, 'Hygeia' General Hospital of Athens, Athens, Greece; [2]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [3]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [4]Department of Anatomy, School of Medicine, Faculty of Health Sciences, National and Kapodistrian University of Athens, Athens, Greece; [5]Schools of Health Rehabilitation Sciences, University of Patras, Patras, Greece

Objectives
Total hip arthroplasty (THA) aims to relieve pain and restore function in patients with end-stage hip disease. Accurate reconstruction of hip anatomy and precise component positioning are important determinants of clinical outcome and implant longevity. Image-based robotic systems facilitate CT-based planning and reproducible execution. This study assessed radiographic accuracy and clinical outcomes after image-based robotic THA at a minimum follow-up of 3 years.
Materials and Methods
This retrospective study included 95 consecutive patients (69 females, 72.6%) who underwent image-based robotic THA between 2019 and 2021. Mean age was 77.5 years (SD 6.2). Mean follow-up was 3.6 years (SD 0.3), with a minimum follow-up of 3 years. Functional outcome was evaluated using the Harris Hip Score (HHS) preoperatively and at latest follow-up. Accuracy of acetabular component placement was assessed by comparing planned versus achieved cup inclination and anteversion.
Results
Mean preoperative HHS was 49.8 (SD 7.8) and improved to 92.4 (SD 4.6) at final follow-up, corresponding to a +42.6-point improvement and an 85.6% relative increase. Mean absolute deviation between planned and final cup inclination was 1.8° (SD 0.4°), while mean absolute deviation for anteversion was 1.3° (SD 0.2°). One patient (1/95, 1.1%) sustained a traumatic dislocation requiring open reduction. No other complications were recorded.
Conclusions
Image-based robotic THA demonstrated high accuracy in restoring hip joint anatomy, with minimal deviation from planned acetabular positioning, and was associated with substantial functional improvement at a minimum of 3 years follow-up. These findings support the reliability of image-based robotic THA in achieving consistent component placement and favorable mid-term outcomes. Longer-term studies are warranted to confirm durability.

P397

THE EFFECTIVENESS OF CLOSED VERSUS OPEN KINETIC CHAIN EXERCISES ON PAIN AND FUNCTIONALITY IN ADULTS WITH PATELLOFEMORAL PAIN SYNDROME: A SYSTEMATIC REVIEW

P. Reppas[1], K. Vogiatzis[1], S. Naoum[2], C. Matzaroglou[1], C. Koutserimpas[1]

[1]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [2]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom

Objective:

To compare the effectiveness of open kinetic chain (OKC) and closed kinetic chain (CKC) exercise interventions in reducing pain and improving functional outcomes in adults with patellofemoral pain syndrome (PFPS).
Materials and Methods:

A systematic review was conducted in accordance with PRISMA guidelines. Randomized controlled trials (RCTs) published in English between 2016 and 2026 were identified through structured searches of the PubMed and Scopus (Elsevier) databases. Inclusion criteria comprised adults aged >18 years with a confirmed diagnosis of PFPS, a minimum sample size of 50 participants, and a follow-up duration of at least six weeks. Studies evaluating OKC, CKC, or combined exercise interventions were included. Outcomes were assessed using validated clinical measures, including the Visual Analogue Scale (VAS) for pain and the Anterior Knee Pain Scale (AKPS/Kujala) for functional assessment.
Results:

A total of 3,548 records were initially identified. After title and abstract screening, 39 studies underwent full-text review, of which five RCTs met the inclusion criteria. Across the included studies, 484 participants were analyzed, with mean ages ranging from 26.3 ± 7.0 to 39 ± 12.7 years and mean body mass index values between 23.4 ± 5.4 and 30 ± 2.3 kg/m². Participants were allocated to CKC, OKC, or combined CKC-OKC intervention groups. Post-intervention VAS scores improved to 2.5–2.7 in the CKC group, 3.7 in the OKC group, and 1.1 ± 1.7 in the combined group. Corresponding Kujala scores increased to 78.4–80.2, 73.3, and 85.9 ± 13.3, respectively, indicating superior pain reduction and functional improvement with combined interventions.
Conclusion:

Exercise-based rehabilitation is effective in managing patellofemoral pain syndrome. Combined OKC and CKC exercise programs demonstrate greater improvements in pain relief and functional outcomes compared with isolated approaches, with CKC exercises showing relative superiority over OKC alone. A multimodal rehabilitation strategy emphasizing CKC exercises is recommended, although further high-quality studies are required to optimize exercise selection and treatment protocols.

P398

HIP DISLOCATION AS A CAUSE FOR AVASCULAR NECROSIS OF THE FEMORAL HEAD

S. Naoum[1], A. Elkhouly[1], N. Davies[1], E. Billis[2], M. Piagkou[3], K. Kaliarntas[4], C. Matzaroglou[4], C. Koutserimpas[4]

[1]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [2]Schools of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [3]Department of Anatomy, School of Medicine, Faculty of Health Sciences, National and Kapodistrian University of Athens, Athens, Greece; [4]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece

Objective:
To describe the clinical course, imaging features, and management of traumatic avascular necrosis (AVN) of the femoral head following posterior hip dislocation in an adolescent, with emphasis on early MRI diagnosis and risk stratification.

Material and Methods:
A 15-year-old male presented eight months after a traumatic posterior hip dislocation sustained during a football match, initially reduced within approximately two hours. Post-reduction radiographs confirmed concentric reduction with a minimally displaced posterior wall fracture and no intra-articular fragments. The patient underwent protected weight bearing and physiotherapy. Recurrent activity-related groin pain developed six months after injury. Clinical assessment and serial radiographs were followed by magnetic resonance imaging (MRI) for evaluation of post-traumatic complications.

Results:
Radiographs demonstrated preserved joint congruence with subtle superolateral femoral head contour irregularity and no definite collapse. MRI revealed a superolateral necrotic lesion with T1 hypointensity, surrounding T2/STIR marrow oedema, and a subchondral low-signal rim with minimal surface flattening, consistent with traumatic AVN, ARCO stage II (Steinberg IIb). The combined Kerboul angle measured 157 degrees, indicating limited necrotic involvement. Given preserved femoral head sphericity and absence of established collapse, conservative management was selected. Follow-up imaging demonstrated increased marginal sclerosis without progression. At 12 months post-injury, the patient remained ambulatory with near-full pain-free range of motion and stable femoral head morphology.

Conclusion:
Traumatic posterior hip dislocation in adolescents carries a substantial risk of femoral head AVN, even following timely reduction. MRI is essential for early diagnosis and staging when symptoms recur. Lesion extent, structural integrity, and risk stratification tools such as the Kerboul angle are critical in guiding management. Selected early-stage cases may be managed non-operatively with careful surveillance.

THE USE OF THE IMAGE-BASED SYSTEM FOR FEMORAL NECK FRACTURES: A CASE SERIES

C. Koutserimpas[1], C. Matzaroglou[1], S. Naoum[2], K. Dretakis[3]

[1]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [2]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [3]Second Department of Orthopaedic Surgery, 'Hygeia' General Hospital of Athens, Athens, Greece

Objective:
To evaluate early clinical and radiographic outcomes of robotic-arm assisted total hip arthroplasty (THA) using dual mobility (DM) cups in patients with displaced femoral neck fractures, with particular emphasis on implant positioning accuracy, biomechanical restoration, and early functional recovery.

Materials and Methods:
A prospective case series was conducted involving six female patients who sustained displaced femoral neck fractures and underwent robotic-arm assisted THA with DM acetabular components. The mean patient age was 64.8 years (range 55–72), with a mean body mass index of 30.4 kg/m² (range 28.9–32.3). Preoperative CT-based planning and intraoperative robotic execution were employed to optimize acetabular cup orientation and restoration of limb length and femoral offset. Outcome measures included radiographic evaluation of component positioning relative to predefined safe zones, assessment of limb length and offset restoration, Harris Hip Score (HHS), time to independent ambulation, and incidence of early postoperative complications.

Results:
All acetabular components were positioned within predefined safe zones (6/6, 100%). Mean absolute deviation from the preoperative plan was 1.3° ± 0.4° for cup inclination and 1.5° ± 0.6° for anteversion. Mean deviation from planned limb length was +1.6 ± 0.4 mm, and from planned offset was +1.7 ± 0.6 mm. No postoperative dislocations, periprosthetic fractures, implant malposition, or early loosening were observed (0/6, 0%). All patients achieved stable, independent ambulation within six weeks postoperatively. Postoperative HHS values ranged from 80 to 92, with a median score of 86.

Conclusion:
Robotic-arm assisted THA combined with dual mobility acetabular components demonstrated high accuracy in implant positioning, reliable restoration of hip biomechanics, and consistent early functional recovery in patients with displaced femoral neck fractures, without early instability. These preliminary findings support the clinical utility of robotic-assisted strategies in the management of fragility hip fractures and warrant further investigation in larger comparative studies.

OSTEOMYELITIS OF THE STERNOCLAVICULAR JOINT MIMICKING AN ANTERIOR THORACIC MASS

S. Naoum[1], C. Matzaroglou[2], M. Tsekoura[2], S. Lampropoulou[2], M. Piagkou[3], C. Koutserimpas[2]

[1]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [2]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [3]Department of Anatomy, School of Medicine, Faculty of Health Sciences, National and Kapodistrian University of Athens, Athens, Greece

Objective:
To highlight the diagnostic challenges of sternoclavicular joint osteomyelitis (SCJ OM), an exceptionally rare entity that may mimic neoplastic or soft-tissue processes.

Material and Methods:
A 69-year-old man with a history of myocardial infarctions, osteoporosis, and chronic respiratory disease presented with a one-month history of progressive swelling over the left sternoclavicular and cervical region, associated with low-grade fever, malaise, and ipsilateral shoulder pain. Clinical examination revealed a firm, tender, mobile anterior chest wall mass with palpable supraclavicular lymph nodes. Laboratory tests demonstrated elevated inflammatory markers (CRP 162 mg/L; neutrophils 13.7 × 10⁹/L). Imaging included computed tomography (CT) and magnetic resonance imaging (MRI) to assess osseous and soft-tissue involvement and exclude malignancy.

Results:
CT showed inflammatory changes surrounding the left SCJ, joint space widening, fat stranding into the supraclavicular and retrosternal spaces, and early cortical sternal erosion suggestive of osteomyelitis. MRI confirmed these findings, excluded alternative diagnoses, and delineated soft-tissue involvement. The patient was treated with a prolonged course of intravenous broad-spectrum antibiotics. Clinical and laboratory follow-up demonstrated complete symptom resolution and normalization of inflammatory markers without the need for surgical intervention.

Conclusion:
Sternoclavicular osteomyelitis is rare and can mimic anterior chest wall masses, posing a diagnostic challenge. MRI plays a pivotal role in confirming diagnosis and guiding management. Early recognition and a multidisciplinary approach allow timely initiation of appropriate therapy, potentially avoiding unnecessary surgery.

10-YEAR EXPERIENCE WITH THE IMAGE-BASED ROBOTIC MEDIAL UNICOMPARTMENTAL ARTHROPLASTY

C. Koutserimpas[1], C. Matzaroglou[1], S. Naoum[2], E. Billis[3], K. Dretakis[4]

[1]School of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [2]Department of Trauma and Orthopaedics, Royal Berkshire Hospital, Reading, United Kingdom; [3]Schools of Health Rehabilitation Sciences, University of Patras, Patras, Greece; [4]Second Department of Orthopaedic Surgery, 'Hygeia' General Hospital of Athens, Athens, Greece

Objective:
To evaluate mid- to long-term implant survivorship, complication rates, and clinical outcomes following robotic arm-assisted medial unicompartmental knee arthroplasty (UKA) in the first reported cohort from Greece, at a minimum follow-up of eight years.

Materials and Methods:
This prospective cohort study included 80 consecutive patients who underwent robotic arm-assisted medial UKA between 2014 and 2016. At final follow-up, five patients were lost, leaving 75 patients available for outcome analysis. Implant survivorship, revision procedures, and surgery-related complications were recorded. Clinical outcomes were assessed preoperatively and at latest follow-up using the Knee Society Score (KSS-knee and KSS-function) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Follow-up duration and revision characteristics were documented.

Results:
The minimum follow-up was eight years, with a mean follow-up duration of 107.6 ± 3.8 months. Two revisions to total knee arthroplasty were required (2/75, 2.7%), both performed using the MAKO robotic system with a primary TKA construct incorporating a 5 mm medial augment. Crude implant survivorship at latest follow-up was 97.3% (73/75).
Significant improvements were observed in all clinical outcome measures. Mean KSS-knee improved from 52.4 ± 11.3 preoperatively to 91.2 ± 7.1 at latest follow-up, and KSS-function improved from 55.6 ± 13.0 to 88.5 ± 9.2 (both $p < 0.001$). Mean WOMAC total score improved from 55.1 ± 12.6 to 13.2 ± 9.1 ($p < 0.001$). WOMAC subscale scores also demonstrated significant improvements in pain, stiffness, and function (all $p < 0.001$). No additional surgery-related complications were recorded.

Conclusion:
Robotic arm-assisted medial unicompartmental knee arthroplasty demonstrated excellent mid- to long-term outcomes at a minimum eight-year follow-up, with high implant survivorship, a low revision rate, and substantial improvements in patient-reported and clinician-based outcome measures. When revision was necessary, conversion to total knee arthroplasty using a robotic-assisted primary construct with a limited medial augment was feasible and effective. These findings support the durability and clinical reliability of robotic-assisted medial UKA.

SCIATIC NERVE SIZE AS A MARKER OF SARCOPENIA IN DISCOPATHY

C. Matzaroglou[1], C. K. Koutserimpas[1], K. Kaliarntas[1], K. Kafchitsas[1], E. Chroni[2], M. T. Tsekoura[1], S. Xergia Sophia[1], J. Gliatis[1]

[1]School of Health Sciences, Department of Physiotherpy and Department of Orthopedics, University of Patras, Patras, Greece; [2]Department of Neurology, University Hospital of Patras, Patras, Greece

Objective: Patients suffering from chronic low back pain with associated sciatica, experience neurological symptoms in the lower back and leg. Ultrasonography (US) has been used recently to characterize sciatic nerves. And because of less daily activities and exercise in these patients are likely to experience sarcopenia. We examine the sciatic nerve with ultrasound in patients with LBP and unilateral radiculopathy (sciatica). We evaluate the possible changes of nerve structure (1) in patients with low back pain with unilateral sciatica due to lumbar disc herniation by ultrasound imaging and possible relation with sarcopenia.

Methods: One hundred and twelve (112) volunteer patients' 224 sciatic nerves, aged 19-86 years old, complained for sciatica and they identified with lumbar disc prolapse in MRI, were studied (2),(6) with US (sciatic nerve). Age, sex, height, weight was recorded, and the size and morphology of sciatic nerve were obtained. Sarcopenia was identified by muscle strength, muscle mass and gait speed assessment using the (&) European Working Group on Sarcopenia in Older People (EWGSOP2) criteria. **Results:** The mean size of sciatic nerves were 0.564± 0.033 cm2 in males and 0.482 ± 0.04 cm2 females respectively. Pearson's correlation analysis showed that the mean size was correlated with height and weight. There was no difference in mean size among the different ages. Women had smaller size of the sciatic nerves than men. Also, the "pathologic sciatic nerves (6) have morphology of "edema" and the size were smaller in patients with recently diagnosed disc prolapse in MRI, and in contrast enlargement sciatic nerves in patients with chronic sciatica, radiculopathy and positive MRI for disc prolapse more than 3 years ago (difference = 0.052 cm2). In addition, 23.3.% were diagnosed with probable sarcopenia and 4.8% with severe sarcopenia. Using regression analyses, sarcopenia was positively associated with sciatica (OR=0.11; CI 0.07-0.14); and age (OR=0.007; CI 0.006-0.01).

Conclusion: Peripheral nerve ultrasonography is reliableAnd reproducible (4), (5) diagnostic method in the hands of experienced examiners. The reliability aspect of measuring sciatic nerves and echo - intensity of the sciatic nerve with ultrasound in patients with LBP and unilateral radiculopathy has received little attention in the literature. Also, the relative magnitude of fat/fibrosis infiltration was observed in all cases of chronic sciatica and radiculopathy. The results of this study show that there is a positive correlation between sarcopenia and sciatica in patients with radiculopathy; this association had not been previously confirmed in Greece. Further research with larger samples is indicated in order clarify the precise association of specific characteristics of patients with sarcopenia and discopathy.

Keywords: Sciatic nerve, sciatica, discopathy, disc prolapse, low back pain, sarcopenia, osteoporosis, ultrasonography of sciatic nerve.

TELE-EXERCISE WITH PILATES PROGRAM IN INDIVIDUALS WITH SPINAL STENOSIS

C. Matzaroglou[1], C. S. Chatzivasilis[1], G. Petropoulou[1], K. Kaliarntas[1], K. Kafchitsas[1], E. Chroni[2], F. Bania[1], A. Evangelatou[1], D. Stathis[1], E. Tsepis[1], S. L. Lampropoulou[1]

[1]School of Health Sciences, Department of Physiotherpy and Department of Orthopedics, University of Patras, Patras, Greece; [2]Department of Neurology, University Hospital of Patras, Patras, Greece

Introduction: After the coronavirus disease (COVID-19) pandemic the tele-exercise has seen as an important mean of therapeutic exercise. This is particularly crucial given that individuals with spinal stenosis often engage with lower levels of physical activity due to barriers of pain and neurological symptoms. **Methods:** We employed synchronous tele-exercise interventions, with Zoom software and Viber software which being the most prevalent platforms (93.8%) in 43 patients [28 female – 15 male, Men age 68m years old] with spinal stenosis certified with MR. Focuses on reducing pain, improving mobility, and strengthening the core through supervised, remote, low-impact movements like lumbar rotations, pelvic tilts, and prone press-ups. It is an effective, accessible alternative to in-person care, using 8-week structured routines to enhance spinal stabilization and reduce nerve compression

Results: We employed synchronous tele-exercise interventions, with Zoom software and Viber software being the most prevalent platforms Interventions primarily focused on muscle strength (Improvement 25.0%) and aerobic training with a median duration of 8.0 weeks [two times per week for one hour]. The mean (standard deviation) adherence was 77.8% (18.7), with variations observed between sex and approaches (synchronous, asynchronous, or hybrid). The most assessed outcomes included physical activity levels (58.3%), adherence (35.3%), pain (25.0%), and physical activity behavior (25.0%). Significant improvements were noted in health status, physical capacity, Anxiety and Depression [HADS - 32%] after tele-exercise implementation.

Conclusions: Tele-exercise interventions, predominantly utilizing synchronous methods and emphasizing muscle strength and aerobic training, are effective and feasible for individuals with Spinal Stenosis. These interventions contribute to improved health outcomes and increased exercise adherence, establishing them as a viable option for promoting physical activity among individuals with SCI. However, the results should be interpreted with caution as the quality of the studies was not considered in this review.

DESIGN OF A HYBRID REHABILITATION PROGRAM FOR PATIENTS WITH PARKINSON'S DISEASE

A. Gotsopoulou[1], E. Nastou[2], E. Trachani[2], E. Papakosta[2], S. Pappas[2], P. Chatziioannou[2], E. Forliaka[2], K. Vogiatzis[2], D. Protopsaltis[2], N. Vasileiadou[2], P. Koutroumpa[2], D. Radi[2], E. Kili[2], V. Kammenou[2], C. Matzaroglou[2], S. Lampropoulou[2]

[1]University of Patras, Patras, Greece; [2]University of Patras, Physiotherapy Department, Rio, Greece

Introduction

Parkinson's disease is a progressive neurodegenerative disorder of the central nervous system, characterized by a broad range of motor and non-motor features that significantly affect patients' functional capacity and quality of life (1). In recent years, therapeutic exercise has been established as a key non-pharmacological intervention, with documented benefits on motor symptoms and quality of life (2). Evidence suggests that different training modalities, including moderate and high-intensity aerobic exercise, progressive resistance training, balance and gait training programs, lead to clinically meaningful improvements. In addition, specialized exercise approaches such as LSVT BIG characterized by high training frequency and a primary focus on large-amplitude movements have been developed (3). However, despite the documented benefits of therapeutic exercise, long-term patient compliance with structured exercise programs remains one of the greatest challenges, limiting the sustainability of therapeutic results.

Purpose

The purpose of the present study was to investigate the most effective forms of therapeutic exercise for improving motor and functional impairments in patients with Parkinson's disease (PD), as well as to design a standardized hybrid exercise program based on international clinical guidelines. Furthermore, it aims to identify the most appropriate method of exercise guidance to ensure optimal patient adherence and long-term commitment.

Materials and Methods

A literature review was conducted in the PubMed, Scopus, and Google Scholar databases, covering the last 10 years, and including systematic reviews and randomized clinical trials. Based on the findings, a hybrid exercise program was designed, with three modes of intervention: (a) face-to-face intervention (including exercise demonstration, verbal guidance, and immediate corrective feedback through physical contact), (b) telerehabilitation via videoconferencing (with exercise demonstration and verbal guidance), and (c) self-guided implementation through an illustrated leaflet (with clear execution instructions). The selection of exercises was based on their effectiveness, safety, and ease of implementation, with the ultimate goal of establishing exercise as a daily routine (Fig. 1). During the pilot implementation of the program, targeted modifications were made, such as rearranging the order of exercises, adding music and rhythmic cues, adjusting intensity, and improving verbal instructions, in order to optimize performance.

Figure 1: Examples of aerobic exercises in sited and standing position

Results

The review indicated that multifactorial exercise programs combining aerobic training, coordination, static and dynamic balance, and functional task practice are the most effective interventions. The proposed rehabilitation program integrates these components and includes exercises performed in various positions and across multiple levels, aiming to enhance functional capacity and motor performance, while prioritizing progression and safety.

Conclusions

Systematic therapeutic exercise substantially improves motor impairments in Parkinson's disease (PD), by enhancing neuroprotective mechanisms. Although most studies demonstrate benefits across a wide range of exercise modalities, the comparative differences between specific approaches have not yet been fully clarified. Therefore, a critical research priority is the optimal "prescription" of exercise in terms of intensity, frequency, duration, and progression, in order to maximize and maintain clinical benefits.

THE EFFECTIVENESS OF COMBINED THERAPEUTIC EXERCISE AND PLATELET-RICH PLASMA IN THE CASE OF KNEE OSTEOARTHRITIS

C. Matzaroglou[1], C. H. Foi[1], C. Koutserimpas[1], K. Kafchitsas[1], K. Kanistras[1], M. Giatra[1], E. Matzaroglou-Chairistanidou[2], D. Papachristou[3], A. Evangelatou[1], D. Makrinioti[1]

[Purpose]: Osteoarthritis is the most common form of arthritis worldwide and has detrimental effects on an individual's quality of life. We compared two interventions—an exercise program alone and an exercise program combined with the intra-articular platelet-rich plasma (PRP) injection—focusing on pain and functionality in patients with mild knee osteoarthritis.

[Participants and Methods]: A total of 76 patients (41 men and 35 women) participated in the study. They were divided equally into the control and intervention groups. To assess knee functionality in both groups, we used state-of-the-art assessment tools, namely the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Knee Injury and Osteoarthritis Outcome Score (KOOS).

[Results]: The results revealed that following the eight-week exercise program, the intervention group showed significantly better values in the WOMAC scale and in three of the four components of the KOOS scale (pain, symptoms, and activities of daily living). Additionally, we observed that the improvement in WOMAC and KOOS scores was significantly better in the intervention group than in the control group. [Conclusion] Combining PRP and exercise therapy can help improve patients' quality of life. However, PRP preparation protocols and exercise prescriptions must be optimized and tailored to individual patient needs.

[Conclusions - Discussion]: The biological mechanism of the combination of PRP and exercise therapy involves PRP-derived grown factors that reduces inflammation, promotes tissue repair and enhance natural body healing process. Concurrently exercise improves muscle strength and joint function contributing to pain relief targeting the complex pathology of Knee OA, which affects the cartilage and the entire joint. The observed improvements in pain and inflammation may lead to a reduction in medical interventions, thereby lowering the risk of surgery and supporting the cost-effectiveness of this combined approach[13]. By empowering patients to control their condition through non-invasive therapies, the long-term outcomes of OA management can be improved, offering a more sustainable approach to pain relief and the long-term

preservation of joint function. Our findings align with those of previous studies demonstrating the efficacy of PRP in treating OA symptoms and achieving better WOMAC parameters, particularly in the early stages of cartilage degradation[14, 15]. Unsurprisingly, better outcomes were observed in younger patients with lower body mass index and low-grade OA. **Keywords:** Knee osteoarthritis, Platelet-rich plasma injection, Exercise therapy

Control group	Intervention group	Mean difference	
Mean ± SD	Mean ± SD		
KOOS pain initial	64.34 ± 13.88	65.63 ± 13.52	−1.29
KOOS symptom initial	71.58 ± 12.38	65.63 ± 13.52	−0.58

EFFECTIVENESS OF AN INNOVATIVE THERAPEUTIC EXERCISE PROGRAM ON PHYSICAL AND COGNITIVE FUNCTION IN PEOPLE WITH MILD COGNITIVE IMPAIRMENT DUE TO ALZHEIMER'S DISEASE: A STUDY PROTOCOL FOR A RANDOMIZED CONTROLLED TRIAL

E. Nastou[1], P. Alexopoulos[2], P. Felemegas[2], M. Skondra[2], M. Frouda[2], S. Xergia[1], E. Billis[1], C. Matzaroglou[1], S. Lampropoulou[1]

[1]University of Patras, Physiotherapy Department, Rio, Greece;
[2]University of Patras, School of Medicine, Patras, Greece

Objective

Individuals with Mild Cognitive Impairment (MCI) are at increased risk of developing dementia, and non-pharmacological interventions recommended for the management/ prevention of their symptoms (1). Physical exercise has emerged as an effective non-pharmacological intervention for reducing age-related cognitive decline and delaying/ inhibiting the progression of MCI to dementia, as well as for improving physical function in people with MCI (2, 3). The purpose of this randomized clinical trial is to investigate the effectiveness of a multicomponent exercise program (MExeProMCI) on cognitive and functional parameters in individuals with MCI.

Materials and Methods

The study was designed as a parallel, single-blind, randomized controlled trial with three arms. 45 volunteers with MCI aged >50 years will participate. They will be assessed before and after the intervention in terms of gait, balance, functionality, global cognitive function, executive function, and word fluency. The intervention will last three months, with a frequency of two sessions per week in small groups. The intervention groups will be: (EXP1) MExeProMCI program with dual-task exercises (combination with cognitive exercises), (EXP2) same program without cognitive exercises, (CG) control group without structured exercise. The analysis will be performed with descriptive statistics and mixed ANOVA ($p<0.05$). Trial registration: ClinicalTrials.gov NCT07334392.

Results

Main outcome measures will be indicators of kinematic and motor analysis (Nexus Vicon) (Fig. 1), balance (Mini-BESTest), gait (FGA), global cognition (MoCA, COGTEL), and executive function (Stroop test). Secondary outcome measures will include physical performance parameters (SPPB), grip strength (HGST), timed walking (TUG, 6MWT), timed repetitive stand- to- sitting (30sec Sit-to-Stand), fear of falling (FES-I), verbal fluency (WoFiBrief), visuospatial ability and memory (CERAD constructional praxis and constructional praxis recall), and neuropsychiatric parameters (GDS, NPI-12).

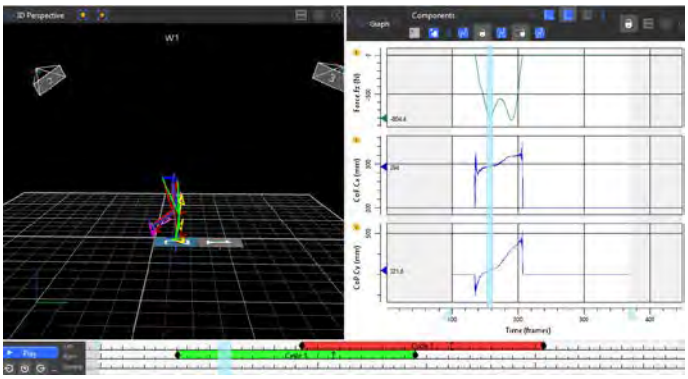

Figure 1. Vertical Ground Reaction Force (Fz) and displacement of Center of Pressure in anterioposterior and mediolateral axis (CoPx, CoPy) in one gait cycle.

Conclusions

It is expected that structured intervention programs will improve physical and cognitive function and contribute to delaying the progression to Alzheimer's disease, while providing useful information on motor variations in people with MCI.

Key words: gait, balance, global cognition, executive function, mci, multicomponent program

BEYOND BONE DENSITY: THE SILENT ALLIANCE BETWEEN SARCOPENIA AND OSTEOPOROSIS IN THE ELDERLY

C. Mocci[1], A. Sanna[1], G. Caggiari[1], C. Doria[1], S. Sardu[1]

[1]SC CLINICA ORTOPEDICA AOU SASSARI, SASSARI, Italy

Introduction:
Sarcopenia and osteoporosis are two chronic conditions frequently associated in older adults, characterized respectively by a reduction in muscle mass and bone mineral density. Both contribute to a progressive functional decline, with an increased risk of falls, fractures, and loss of independence. Early and multidimensional diagnosis is essential to identify individuals at risk and to initiate targeted therapeutic interventions. This study aims to evaluate the prevalence and interaction between sarcopenia and osteoporosis in an elderly population through the combined use of bioelectrical impedance vector analysis (BIVA), laboratory testing, physiotherapeutic functional assessments, and quality-of-life questionnaires.
Materials and methods:
A total of 100 patients aged over 65 years, with a residual life expectancy of at least six months, were recruited from geriatric and rehabilitation

services. Each participant underwent blood sampling to assess key bone and muscle markers, including vitamin D, calcium, parathyroid hormone, albumin, and creatinine. Body composition was evaluated using BIVA to detect alterations in lean mass and hydration status. Functional assessment was performed using standardized physiotherapy tests (Timed Up and Go, 5 Times Sit-to-Stand, and Handgrip Strength), while quality of life was assessed using the SF-36 questionnaire. Sarcopenia was diagnosed according to EWGSOP2 criteria, while osteoporosis was identified based on medical history, densitometric findings, and clinical data.
Results:
In the studied sample, the prevalence of sarcopenia was 34%, while osteoporosis was identified in 41% of patients. Twenty-two percent of participants presented with both conditions. Sarcopenic patients showed significantly reduced handgrip strength and poorer performance on functional tests, with statistically significant differences in Timed Up and Go and 5xSTS completion times. BIVA analysis revealed a vector displacement consistent with reduced active cell mass and impaired nutritional status. SF-36 scores demonstrated a marked deterioration in quality of life, particularly in domains related to physical functioning and pain perception, among patients with sarcopenia and osteoporosis. Furthermore, individuals affected by both conditions exhibited a significant vitamin D deficiency, with serum levels below 20 ng/mL in more than two-thirds of cases.
Conclusions:
The integration of laboratory investigations, instrumental assessments, and functional testing allows for a more accurate identification of frailty in older patients. The coexistence of sarcopenia and osteoporosis represents a strong indicator of functional impairment and reduced quality of life. The findings of this study support the importance of multidisciplinary screening strategies in the population aged over 65, aimed at preventing disability, optimizing therapeutic interventions, and improving long-term clinical outcomes.

HYPOPARATHYROIDISM: INCIDENCE AND PREVALENCE IN THE ITALIAN REGION OF VENETO

C. Mogno[1], G. Voltan[1], G. Contini[1], C. Mian[1], L. Salmaso[2], M. Saia[2], V. Camozzi[1]

[1]Endocrinology Unit, University Hospital of Padua, Padua, Italy; [2]Clinical Governance Unit, Azienda Zero Regione Veneto, Padua, Italy

INTRODUCTION
Hypoparathyroidism is a disorder characterized by parathyroid hormone deficiency, leading to hypocalcemia, hyperphosphatemia, and hypercalciuria. Worldwide prevalence ranges between 6.4-37 cases per 100,000 people, while incidence is estimated at 0.8-2.3 cases per 100,000 people per year.
OBJECTIVES
This study aimed to evaluate the incidence and prevalence of hypoparathyroidism in the population of the Veneto Region in Italy.
MATERIALS AND METHODS
A retrospective, population-based study was conducted using population registry and administrative healthcare databases of the Veneto Region. Prevalent cases were identified between 2012 and 2025 through either hospital diagnoses of hypoparathyroidism (ICD-9 252.1) or healthcare co-payment exemptions (national code 026 combined with ICD-9 252.1) whichever occurred first. Incident cases were assessed from 2013 to 2024 to exclude prevalent cases. Individuals alive on 01/01/2025 were linked to thyroidectomy procedures and to co-payment exemptions for rare diseases associated with hypoparathyroidism.
RESULTS
During the study period, a total of 3,460 prevalent cases of hypoparathyroidism were identified, corresponding to a mean yearly prevalence of 44.21 cases per 100,000 inhabitants. The total number of incident cases was 1,752, with a mean yearly incidence of 2.99 cases per 100,000 inhabitants. Sex-specific analyses showed that women had a higher mean yearly incidence than men (4.56 vs 1.36 cases per 100,000) and a higher mean yearly prevalence (70.92 vs 16.43 cases per 100,000). The age group with the highest incidence in women was 50–54 years, accounting for 11.9% of incident cases (6.74 per 100,000), whereas in men it was 55–59 years, representing 13.7% of incident cases (2.44 per 100,000). Rare diseases associated with hypoparathyroidism, identified through specific exemption codes, accounted for 1.18% of prevalent cases until 01/01/2025.
CONCLUSIONS
The incidence and prevalence of hypoparathyroidism in the Veneto region are consistent with global estimates. Women show both a higher incidence and prevalence than men, and in both sexes the highest incidence occurs between the fifth and sixth decades of life. Finally, although considered rare diseases, these conditions account for more than 1% of prevalent hypoparathyroidism cases.

EFFECT OF CHRONIC ADMINISTRATION BASED ON HYDROXYAPATITE-CALCITONIN POLYMERIC NANOPARTICLES FOR OSTEOPOROSIS TREATMENT IN A STREPTOZOTOCIN-INDUCED DIABETES MICE MODEL

C. Mothe[1], J. Leos[1], M. Franco[1], L. Ponce[2], A. Martínez[2], J. Jiménez[2], D. Zárate[1], C. Rodriguez[1]

[1]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Mexico; [2]Universidad Autónoma de Tamaulipas, Reynosa, Mexico

Type-1 Diabetes is one of the most prevalent chronic diseases worldwide, principally characterized by chronic hyperglycemia, which results in painful peripheral neuropathy, bone deterioration and high risk of bone fractures. Recently, the development of nanoparticles has acquired great relevance to promote bone regeneration, because of their oral administration and easy functionalization with molecules can improve the effects of pharmaceutical drugs accelerating considerably the process of regeneration. Nanoparticles of hydroxyapatite-calcitonin were synthetized and evaluated as an alternative treatment. The capability to promote proliferation and mineralization was determined in vitro, meanwhile in vivo, the repair of bone microarchitecture was evaluated using a streptozotocin-induced diabetes mice model. *Invitro*, the administration of hydroxyapatite-calcitonin affects the cell viability, bone mineralization process and the expression of bone proteins such as alkaline phosphatase, osteoprotegerin, osteocalcin and type 2/4 bone metalloproteins related to bone formation. Additionally, *invivo* female BALB/c mice treated with hydroxyapatite-calcitonin nanoparticles (NHCal) showed significant improvement of bone recovery such as an increase of bone volume percentage and trabecular number. Meanwhile,

the histological analysis revealed a significant increase of sympathetic innervation expression, blood vessel formation and the number of infiltrating macrophages into the bone marrow compared to healthy mice.

P410

ANKYLOSING SPONDYLITIS COMPLICATED BY HYPOPHOSPHATASIA AND RENAL COMORBIDITY: A CASE REPORT

C. N. B. Bas[1], K. K. Kalkan[1], C. B. Bes[1]

[1]cam and sakura city hospital, Istanbul, Türkiye

Objective(s)

To highlight how renal comorbidity, pregnancy–postpartum period, latent tuberculosis infection, and rare genetic disorders influence treatment decisions in the management of ankylosing spondylitis (AS).

Material and Methods

A 25-year-old female patient with a 7-year history of ankylosing spondylitis and a solitary kidney secondary to vesicoureteral reflux was evaluated. Initial treatment consisted of nonsteroidal anti-inflammatory drugs (NSAIDs); however, full-dose therapy could not be administered due to renal comorbidity. During follow-up, the patient became pregnant, and the disease remained in remission throughout pregnancy. In the postpartum period, disease flare occurred with complaints of back and low back pain. Magnetic resonance imaging revealed bilateral active sacroiliitis.

Results

Biological therapy was planned; however, interferon-gamma release assay testing was positive. Following isoniazid prophylaxis, certolizumab therapy was scheduled, but the patient declined biological treatment. Postpartum lumbar magnetic resonance imaging demonstrated vertebral height loss, which was interpreted as early-onset osteoporosis. Genetic testing revealed a heterozygous mutation in the ALPL gene, consistent with hypophosphatasia, and a likely pathogenic mutation in the COL4A3 gene, prompting follow-up for possible Alport syndrome.

Conclusion(s)

As the patient achieved clinical remission with regard to ankylosing spondylitis, follow-up with NSAIDs was continued, and teriparatide therapy was initiated for early-onset osteoporosis. This case demonstrates how renal comorbidity, pregnancy–postpartum period, latent tuberculosis infection, and rare genetic disorders can significantly impact treatment decisions in ankylosing spondylitis. Coexisting genetic and systemic diseases necessitate a personalized treatment approach, and this case emphasizes the importance of disease activity, comorbidities, and patient preferences during the transition to biological therapy.

THE SIMILARITIES AND DIFFERENCES BETWEEN ATYPICAL FEMORAL FRACTURES (AFFS) AND ATYPICAL PERIPROSTHETIC FEMORAL FRACTURES (APFFS): A SCOPING REVIEW

C. Patamamongkonchai[1], T. Tutaworn[1], T. Songpatanasilp[1], O.-A. Phruetthiphat[1]

[1]Department of orthopedics, Phramongkutklao hospital, Bangkok, Thailand

Atypical Femoral Fractures (AFFs) and Atypical Periprosthetic Femoral Fractures (APFFs) are rare but significant orthopedic challenges, primarily linked to the long-term use of anti-resorptive agents like bisphosphonates.

Shared Etiology and Pathophysiology: The core pathology for both is substantially suppressed bone turnover due to prolonged BP exposure. This suppression causes microdamage to accumulate without repair, leading to bone hyper-mineralization and brittleness.

Clinically, they share hallmark features, including Prodromal thigh, groin pain lasting weeks to months. And radiologically, A transverse or short oblique fracture line originating at the lateral cortex with minimal comminution, Focal lateral cortical thickening. Leading to the poor outcomes, including delayed healing and high nonunion rates, due to the suppressed healing capacity.

Key Distinctions and Management lies in the context and surgical complexity: for context: AFFs occur in the intact femoral diaphysis and are defined by the ASBMR criteria; APFFs occur around a pre-existing femoral implant, which excluded by the ASBMR criteria. And for surgical Management: AFFs are primarily treated with Intramedullary Nailing. APFFs present a greater technical challenge, often requiring complex options like Open Reduction with Internal Fixation using plates with augmentation, or revision hip arthroplasty.

For both, the anabolic agent Teriparatide is a recommended adjunct to stimulate bone formation and overcome the suppressed bone turnover, thereby accelerating healing. The evidence suggests APFFs are a biologically distinct entity, and a reconsideration of the ASBMR criteria to include PFFs with atypical features is necessary.

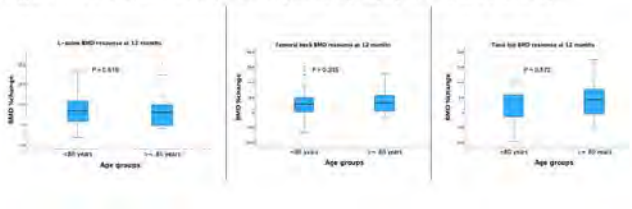
BONE DENSITY RESPONSE TO ROMOSOZUMAB IS MAINTAINED IN THE OLDEST OLD (≥80 YEARS): REAL-WORLD DATA FROM THE UK

C. Rakieh[1], D. Powell[1], T. Roberts[1], J. Cole[1], C. Mennan[1]

[1]Metabolic Bone Unit, The Robert Jones & Agnes Hunt Orthopaedic Hospital NHS Foundation Trust, Oswestry, United Kingdom



Objectives:
To compare 12-month BMD response to romosozumab in adults ≥80 years versus <80 years and to examine predictors of response, including baseline BMD and bone turnover (PINP).
Materials and Methods:
This prospective, real-world study was undertaken at a UK metabolic bone centre. Post menopausal women initiated on romosozumab for osteoporotic BMD and imminent fracture risk were included. DXA was performed at baseline and 12 months, and percentage BMD change at the total hip (TH), femoral neck (FN), and lumbar spine (LS) was calculated. Twelve-month BMD response was compared between adults ≥80 years and <80 years using independent t-tests (α=0.05). Linear regression models assessed predictors of response.
Results
Among 114 patients, 30 were ≥80 years. Age ranged from 42 to 91 years. The ≥80 group had significantly lower FN BMD, trabecular bone score (TBS), and eGFR, and higher QRISK3 scores compared with those <80 years (all p<0.005). At 12 months, romosozumab increased BMD by 13.1% (±10.3) at the LS, 5.7% (±8.4) at the TH, and 4.1% (±10.6) at the FN (all p<0.001). In multivariable models adjusted for age, baseline BMD, and baseline PINP, baseline BMD was negatively associated with response at the TH (B=−40, p=0.001) and LS (B=−32.2, p<0.001). Each 10 ng/mL increase in baseline PINP contributed to a 1.26% gain at the LS and 0.6% at the FN (both p<0.05). Age did not attenuate anabolic response at any site. Twelve-month BMD response was similar in patients ≥80 and <80 years at all sites (all p>0.05; Figure 2).
Conclusions
Romosozumab elicits significant bone density gains in adults ≥80 years, with preserved anabolic response across all skeletal sites. Age alone does not blunt treatment effect, while baseline turnover and bone density influence response magnitude. These findings support romosozumab as an effective option in the oldest-old, a population with the highest unmet fracture risk.

NURSE'S ROLE IN PAIN ASSESSMENT FOR ADULTS WITH OSTEOGENESIS IMPERFECTA

C. Rebelo Silva[1,2], M. C. Portelada[1,2], J. Laranjeira[1,2], A. Barcelos[1,2,3]

[1]Rheumatology Department, Unidade Local de Saúde da Região de Aveiro, Aveiro – Portugal, Aveiro, Portugal; [2]Aveiro Rheumatology Research Centre, Egas Moniz Health Alliance – Portugal, Aveiro, Portugal; [3]EpiDoC Unit - NOVA Medical School, Comprehensive Health Research Centre (CHRC), NOVA University, Lisbon – Portugal, Lisbon, Portugal

Objective
Osteogenesis imperfecta (OI) is a hereditary connective tissue disorder characterized by various phenotypic manifestations, including bone fragility, osteopenia, recurrent fractures, and progressive skeletal deformities, which can sometimes be lethal. Pain is a common experience for patients with OI, yet few studies address this issue. Also, a few healthcare professionals recognize this symptom. This study aims to evaluate the role of nursing in assessing pain and its intensity in OI patients.
Materials and Methods
Sociodemographic and clinical data were collected from OI patients treated in our department during 2025. Pain was evaluated using the Visual Analogue Scale (VAS), which measures pain intensity from 0 to 100 mm. Descriptive statistical analysis was performed.
Results
Ten patients (seven women) were evaluated (Table 1). The mean age was 53.2 years, and 3 patients were diagnosed in adulthood. According to the Sillence classification, OI type I was the most common form (n=5). The initial fractures primarily occurred in the lower limbs (n=6) during childhood. Kyphoscoliosis was the most prevalent musculoskeletal deformity (n=6). Bisphosphonates were the preferred anti-osteoporotic treatment (n=8). Most patients reported pain during the nursing consultation, with VAS score ranging from 10 to 60 mm. The highest pain levels were observed in patients who had experienced a recent fracture.
Conclusions
Our findings indicate that pain is a prevalent experience among adults with OI, affecting almost all patients in the study. However, in many existing studies, pain is often only assessed when a fracture occurs. Nursing professionals play a crucial role in evaluating this symptom.

ACUTE-PHASE RESPONSE FOLLOWING ZOLEDRONIC ACID INFUSION IN OSTEOPOROSIS PORTUGUESE PATIENTS

C. Rebelo Silva[1,2], M. C. Portelada[2,3], J. Laranjeira[2,3], C. Mazeda[1,2,4], A. Barcelos[1,2,4]

[1]Rheumatology Department, Unidade Local de Saúde da Região de Aveiro, Aveiro – Portugal, Aveiro, Portugal; [2]Aveiro Rheumatology Research Centre, Egas Moniz Health Alliance – Portugal, Aveiro, Portugal; [3]Rheumatology Department / Unidade Local de Saúde da Região de Aveiro, Aveiro, Portugal; [4]EpiDoC Unit - NOVA Medical School, Comprehensive Health Research Centre (CHRC), NOVA University, Lisbon – Portugal, Lisbon, Portugal

Objective

Zoledronic acid infusion is commonly associated with an acute-phase response (APR), a transient inflammatory reaction characterized by fever, myalgia, and flu-like symptoms. This study aims to describe the frequency of APR and the predictors associated with its occurrence in a Portuguese osteoporosis population receiving zoledronic acid infusion.

Material and Methods

Prospective observational study of patients who received zoledronic acid infusion between May and December 2025 in our Fracture Liaison Service. APR was defined as the presence of at least one symptom (fatigue, myalgia, malaise, diffuse pain, headache, or fever) within 72 hours post-infusion and was assessed through a nurse-led telephone consultation one week after treatment.

Baseline demographic and clinical characteristics, comorbidities, analytical parameters, and infusion-related variables were collected. Baseline characteristics were compared according to APR status. Categorical variables were compared using the χ^2 test or Fisher's exact test, and continuous variables using Student's t-test or Mann–Whitney U test, as appropriate. A p-value <0.05 was considered statistically significant.

Variables considered clinically relevant and/or associated with APR in univariate analyses were included in the multivariable logistic regression model.

Results

Our cohort included 105 patients who received zoledronic acid infusion, and APR symptoms were observed in 53 (50.5%). Socio-demographic and clinical data are presented in Table 1.

The most frequent symptoms were fatigue (64.2%), myalgia (62.3%), malaise (58.5%), and diffuse pain (53.8%). Symptom onset occurred predominantly on the first (50.0%) and second day (66.0%), and symptoms typically lasted 1-2 days. First zoledronic acid infusion (OR 4.40, 95% CI 1.81–10.65, p=0.0010) and younger age (OR 0.93 per year, 95% IC 0.88–0.99, p=0.0246) were independently associated with APR symptoms in a multivariable logistic regression model.

Sex and calcium levels were not independently associated with APR.

Conclusion

APR following zoledronic acid infusion was frequent in this real-world osteoporosis cohort, particularly among younger patients and those receiving their first infusion. Nurse-led telephone follow-up proved to be a valuable strategy for the early identification and characterization of APR symptoms, reinforcing the pivotal role of nursing care in post-infusion monitoring, patient education, and timely symptom management.

DISUSE OSTEOPOROSIS: A CASE SERIES

C. Rua[1], C. Silva[1], M. Patela[1], R. Vieira[1,2]

[1]ULS Gaia e Espinho, Vila Nova de Gaia, Portugal; [2]Department of Medical Sciences Aveiro's University, Aveiro, Portugal

Objective: To describe a series of patients with disuse osteoporosis (DOP) and assess clinically relevant bone mineral density (BMD) changes by paired dual-energy X-ray absorptiometry (DXA) following anti-osteoporotic treatment.

Material and Methods: Patients with DOP followed in a rheumatology department were analysed. DOP was defined as a T-score ≤ −2.5 occurring in the context of reduced mechanical loading due to prolonged immobilization (bed-bound or wheelchair dependency), in the absence of primary bone disease. BMD was assessed at baseline and follow-up by DXA (Lunar DPX GE®) at the lumbar spine, femoral neck, total hip and radius. Least significant change (LSC) of the DXA scanner (0.03 g/cm³) was used to define a meaningful BMD variation. Anti-osteoporotic treatment was prescribed according to clinical indication. Paired comparisons were performed using the Wilcoxon signed-rank test.

Results: Seven patients were analysed (median age 53 years;19–81); 14% were female, with a median follow-up of 20 months (4–42). Conditions associated with reduced mechanical loading included neuromuscular disease, spinal cord injury and post-stroke hemiparesis. Additional secondary osteoporosis risk factors were common, including corticosteroid use, inflammatory disease, hypogonadism and prior oncological treatment. Prior fragility fractures were present in 71.4% of patients, mainly vertebral. Five patients had paired baseline and follow-

up DXA (median interval 37.5 months; 26–48) and were evaluable for longitudinal BMD analysis. The median treatment duration before follow-up DXA was 20 months (12–65). Four patients were treated with denosumab and one with teriparatide (12 months of follow-up). BMD increased at the lumbar spine (+15.1%), femoral neck (+12.3%), total hip (+18.1%) and total radius (+6.38%, n=1); a decrease of −1.14% at the one-third radius was observed in one patient (n=1). No differences were observed. One patient sustained a distal femur fragility fracture after 24 months of denosumab treatment.

Conclusion: In this cases series, denosumab was associated with increases in BMD in patients with DOP, in line with previous reports. Data on the use of teriparatide in this specific population are currently lacking. Further prospective studies are needed to define treatment strategies in DOP.

Table 1 - BMD Changes After Treatment with Denosumab (n=4) and teriparatide (n=1)

FROM WRIST TO HIP: CAN EARLY FLS INTERVENTION AFTER A DISTAL RADIUS FRACTURE PREVENT THE NEXT FRAGILITY FRACTURE

A. E. Elsalamwy[1], D. C. Charchoglyan[2], S. Z. Zidan[3], C. S. Singh[1]

[1]Trauma & Orthopaedic Department, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-sea, United Kingdom; [2]Emergency Department, Southend on sea, United Kingdom; [3]Trauma & Orthopaedic Department, North Middlesex University Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom

Background

Distal radius fracture (DRF) is frequently the first clinical manifestation of osteoporosis and a strong predictor of future major fragility fractures, particularly hip fractures. The risk of a subsequent hip fracture is reported to be **1.4–3.5 times higher** following a DRF, with the majority occurring within two years. This "imminent risk" period represents a key opportunity for secondary prevention. Despite NICE and Royal Osteoporosis Society (ROS) guidance, many patients with DRF are not referred for bone health assessment. The Fracture Liaison Service (FLS) model provides a structured approach for identification, investigation, and treatment. We evaluated whether FLS-led management following DRF at Southend University Hospital reduced the risk of subsequent hip and other fragility fractures.

Methods

We retrospectively reviewed all adults aged ≥50 years presenting with an index DRF between January 2018 and December 2024. Patients were stratified into:

(1) **FLS group:** completed FLS pathway (assessment ≤90 days, DXA scan, initiation of anti-osteoporosis therapy, and falls assessment).
(2) **Non-FLS group:** no referral or incomplete pathway.

The primary outcome was hospital admission with a hip fracture within 24 months. Secondary outcomes included any new major osteoporotic fracture and treatment adherence. Kaplan–Meier survival analysis and multivariable Cox regression were used to estimate hazard ratios (HR) adjusted for age, sex, comorbidities, and previous fractures.

Results

Among **612 eligible patients** (mean age 72 ± 10 years; 78% female), **48%** received full FLS follow-up. Over 24 months, **15.6%** of the non-FLS group sustained a second fragility fracture compared with **8.9%** in the FLS group. Hip fractures occurred in **5.1% vs 2.4%**, respectively. FLS management was associated with a **34% lower hazard** of any secondary fracture (adjusted HR 0.66; 95% CI 0.48–0.91; p = 0.01).

Conclusions

Patients presenting with a distal radius fracture face a high imminent risk of subsequent hip or major fragility fractures. Comprehensive post-fracture management through an FLS pathway significantly reduced secondary fracture rates within two years. These findings reinforce the value of universal FLS coverage and early bone-health optimisation to transform the distal radius fracture from a precursor to a preventable event in the fracture-care continuum.

TREAT-TO-TARGET APPROACH IN OSTEOPOROSIS: A REAL-WORLD COMPARISON OF TERIPARATIDE AND DENOSUMAB

C. Silva[1], C. Rua[1], M. Patela[1], P. Pinto[1], T. Meirinhos[1]

[1]ULS Gaia e Espinho, Vila Nova de Gaia, Portugal

Objective: To compare the effectiveness of teriparatide and denosumab in achieving a predefined Treat-to-Target (T2T) goal in a real-world osteoporosis (OP) cohort.

Material and Methods: A retrospective observational study was conducted including OP patients treated with teriparatide for 18-24 months or denosumab, with baseline and follow-up dual-energy X-ray absorptiometry after 2-3 years. The index skeletal site (IS) was defined as the site with the lowest baseline T-score. The primary outcome was target attainment, defined as achieving a T-score > −2.5 at the IS among patients below target at baseline; target maintenance was assessed separately. Secondary outcomes included site-specific target status and absolute bone mineral density (BMD) change.

Results: Forty-four patients were included (21 teriparatide, 23 denosumab). Most were female (84.1%), with a median treatment initiation age of 70 years. Prior fragility fractures (68.2%) and previous bisphosphonate exposure (65.9%) were common. Baseline characteristics were comparable between groups. The lumbar spine was the most frequent IS, with median baseline T-score of −3.5 in the teriparatide group and −3.1 in the denosumab group (p = 0.254). Among patients below target at baseline, target attainment occurred in 17.6% of teriparatide-treated and 36.4% of denosumab-treated patients (p=0.288). No patient below target at all three skeletal sites achieved simultaneous target attainment. The lumbar spine (LS) demonstrated the highest

attainment rates (28.6% vs 46.7%; p = 0.316). All teriparatide-treated patients already above target maintained target status (n = 4). Median BMD gains at the IS were similar between treatments (0.044 g/cm² vs 0.053 g/cm²; p=0.885), with greater gains at the LS (0.086 vs 0.065 g/cm²; p = 0.696). Treatment type was not associated with BMD change in adjusted analyses; smaller gains were observed with increasing age and higher baseline T-scores. Fragility fractures during follow-up were infrequent (2 vs 1; p=0.599).

Conclusion: In this real-world cohort, attainment of the predefined T2T goal was modest. Improvements were greatest at the LS, and no significant differences were observed between teriparatide and denosumab in adjusted BMD changes, highlighting challenges of implementing a T2T strategy in routine OP care.

Table 1. Baseline characteristics of the study population according to treatment strategy

Variable	Teriparatide (n=21)	Denosumab (n=23)	Overall (n=44)	*p*-value

TH	0.024 (0.001-0.057) (n=18)	0.035 (0.012-0.072) (n=17)	0.443

Values are expressed as median (IQR), with the number of patients with available data indicated in parentheses, or as n/N (%), where N represents the number of patients with available data for each analysis. Δ indicates change from baseline to follow-up. BMD – bone mineral density; FN – femoral neck; ISS – index skeletal site; LS – lumbar spine; NA – not available; TH – total hip.

P418

REDUCTION OF SUBCHONDRAL BONE MARROW LESIONS CONCURRENT WITH EARLY RECOVERY OF TRABECULAR BONE MINERAL DENSITY IN KNEE OSTEOARTHRITIS FOLLOWING RANKL INHIBITOR ADMINISTRATION FOR THE TREATMENT OF OSTEOPOROSIS: IMPLYING HUMAN OSTEOPOROTIC OSTEOARTHRITIS?

C. Sun[1], Y. Xue[1]

[1]Tianjin medical university general hospital, Tianjin, China

Objective
To investigate the correlation between reduction of subchondral bone marrow lesions (BMLs) and early recovery of trabecular bone mineral density (TBMD) in osteoporosis (OP) patients with symptomatic knee osteoarthritis (KOA).
Material and Methods
A retrospective study included 56 OP patients (mean age 58.05±5.19 years) with symptomatic KOA and subchondral BMLs refractory to nonsteroidal anti-inflammatory drug therapy. Patients received a RANKL inhibitor (60mg subcutaneously) for OP treatment. Clinical symptoms (visual analog scale and Western Ontario and McMaster Universities Osteoarthritis Index scores), health-related quality of life (Short Form-36), BMLs (modified Whole-Organ magnetic resonance imaging Score and area measurement), knee TBMD (computed tomography Hounsfield unit values), systemic bone mineral density (dual-energy x-ray absorptiometry), and bone turnover markers were evaluated at baseline, 4 weeks, 3 months, and 6 months.
Results
Following a RANKL inhibitor administration, knee pain significantly decreased from baseline (6.64±0.79) at 1-week (4.80±0.93), persisting through 3-month follow-up (1.43±0.49) (all P<0.05). BML scores improved from baseline (5.13±0.96) at 4-week (3.80±0.74) and 3-month (2.82±0.98) follow-ups (both P<0.05), with improvement rates of 26.79% and 46.42% respectively. BML areas decreased from 467.39±112.43 mm² at baseline to 343.38±93.55 mm² at 4 weeks and 294.30±94.55 mm² at 3 months (both P<0.05). Computed tomography Hounsfield unit values significantly increased from baseline (99.61±9.82) to 4-week (110.88±9.67) and 3-month (123.32±11.34) follow-ups (both P<0.05). At 3-month follow-up, reduction in BML areas positively correlated with increased computed tomography Hounsfield unit values (r=0.329, P<0.05). Bone turnover markers significantly decreased, and systemic bone mineral density improved at 6-month follow-up.
Conclusions
In this clinical study, after the application of a RANKL inhibitor for OP treatment, BMLs and knee pain were effectively reduced in OP patients with symptomatic KOA and BMLs. In addition, the correlation between early recovery of TBMD and reduction in BML area was also demonstrated. This study supports the concept of osteoporotic osteoarthritis (OPOA) and highlights the potential of subchondral bone as a target for KOA treatment.

PULSE DISTRIBUTION ANALYSIS (PDA) AS A DIGITAL BIOMARKER FOR QUANTIFYING MICROCIRCULATORY RESPONSES AND PREDICTING FUNCTIONAL RECOVERY IN ADHESIVE CAPSULITIS

C. T. Chen[1], M. J. Wang[1], H. Hsiu[2], R. N. Yu[2], F. C. Lin[3], C. M. Chang[4]

[1]Department of Chinese medicine, Taipei City Hospital, Renai Branch, Taipei, Taiwan; [2]Graduate Institute of Biomedical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan; [3]Department of Rehabilitation, Taipei City Hospital, RenAi Branch, Taipei, Taiwan; [4]Center for Traditional Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

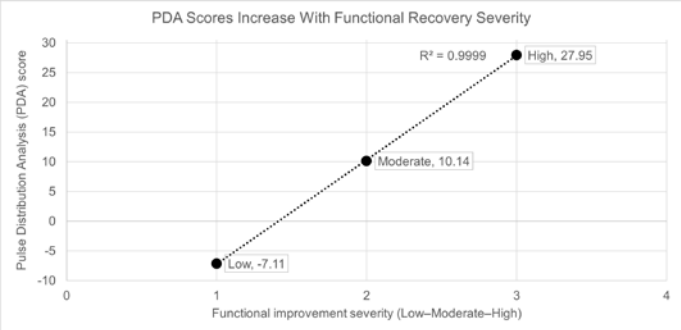
Objective

To evaluate the clinical utility of the Pulse Distribution Analysis (PDA) scoring system—a non-invasive digital biomarker—for quantifying microcirculatory hemodynamic responses and predicting functional recovery in patients with adhesive capsulitis.

Materials and Methods

Seventy patients with adhesive capsulitis were evaluated using Shoulder Pain and Disability Index (SPADI) and PDA scores derived from radial blood pressure waveforms before and after 3 weeks treatment to characterize longitudinal hemodynamic patterns. To validate the clinical relevance of PDA, four stratification strategies were compared: (1) changes in SPADI pain scores; (2) changes in SPADI disability scores; (3) total SPADI scores classified by median split; and (4) disease duration. Subjects were stratified using median-split and extreme-responder contrast approaches to determine which clinical parameter best reflected the physiological changes captured by the PDA scoring system.

Results



Stratification based on changes in SPADI disability scores demonstrated the strongest association with PDA variations. This functional recovery metric achieved perfect between-group explanatory power ($R^2 = 1.0$) and an inter-group correlation coefficient approaching 1.0, indicating clear separation of vascular response patterns. In contrast, stratification based on pain improvement, overall disease severity, or disease duration showed greater within-group variability and reduced discriminatory performance. Individual-level scatter plot analysis further demonstrated a moderate correlation ($R \approx 0.55$) between PDA score changes and functional disability improvement.

Conclusion

The PDA scoring system represents a robust digital biomarker that closely aligns with functional recovery in adhesive capsulitis. As microvascular responses were more strongly associated with disability improvement than with pain relief or disease duration, PDA provides an objective and physiologically meaningful tool for monitoring rehabilitation progress and predicting recovery trajectories.

P420

A MIDDLE AGE MAN WITH OSTEOGENESIS IMPERFECTA SWITCHING FROM DENOSUMAB TO ZOLENDRONIC ACID

C. W. Ho[1]

[1]United Christian Hospital, Hong Kong SAR China

A 60-year-old man was referred to the Endocrine Clinic in Nov 2025 for newly diagnosed osteogenesis imperfecta (OI) with history of recurrent fracture. He was detected to have OI after family screening of his son who was the proband of the family. The patient had fracture of metatarsal during sports activity at primary school age, then had fracture of the right upper arm during Taekwondo at age 22. He fell from stairs at age 58 and fractured his left 4th and 5th metatarsal. He did not receive any operation for fracture before. For family history, his mother had history of recurrent fracture. His son had fracture at 2-3 years old then second fracture at age 20s. His elder brother and elder sister did not have any history of fracture. Physical examination showed short stature of height 1.52m. BMI was 22.8. There was mild blue sclera and transparent teeth but no abnormal facies, no hearing loss, no limb deformity and no joint laxity. There was no thoracic cage deformity and no heart murmur. His genetics test revealed that he was heterozygous for the familial COLIA2 p.Gly193Ser missense variant, c. 577G>A. This variant has been reported in multiple cases of osteogenesis imperfecta type 1. The genetic mutation was the same as the proband.

Blood test showed normal bone profile. DXA in 11/2024 showed T score -4.4 at the lumbar spine, T score -2.7 at left total hip and T score of -2.2 at the left femoral neck(FN). The patient was given denosumab (Dmab) 60mg sc in Feb 2025 and Aug 2025 by orthopaedic surgeon. The b-CTX was below 50pg/ml (35-836) and P1NP was below 10 mcg/l (30-110) in Nov 2025. After discussion on the drug treatment, he decided to change to zolendronate 5mg IV infusion, to be scheduled in Feb 2026. The dilemma in this case lies in the difficulty of deciding whether to continue Dmab or switching to bisphosphonate. A case series on 10 adults with OI reported 2.6% gain in BMD at LS (P=0.100) and 4.4% BMD gain at FN (P=0.051) after using Dmab for 12 months. Bisphosphonate in OI patients was studied in 8 studies as compared with placebo, which showed BMD rise in LS in all studies and BMD rise in FN in some studies. Though fracture risk reduction was proven only in two of the studies. Hence, bisphosphonate has more robust evidence. On the other hand, the risk of BMD loss and risk of multiple vertebral collapse upon switching from Dmab to bisphosphonate was explained. In order to minimize risk of rebound vertebral collapse, the patient was planned have bone resorption marker, b-CTX, checked every 3 months after stopping Dmab and another dose of zolendronate may be needed earlier if there is rapid rise in b-CTX.

P421

COMPARISON OF HISTOLOGICAL AND BIOCHEMICAL FINDINGS WITH MAGNETIC RESONANCE IMAGING ON THE DEGENERATION SEVERITY OF MENISCUS

C. Whanyong[1]

[1]University of Catholic Kwandong , International St. Mary's Hospital, Incheon, South Korea

Objectives: The aim of this study is to determine whether degeneration severities of meniscus assessed using magnetic resonance imaging (MRI) would well estimate those assessed using histological and biochemical examinations.

Material & Methods: Seven lateral menisci from knees with osteoarthritis undergoing total knee arthroplasty (study group) and five from normal controls (control group) were examined for this study. Degeneration severities of the menisci were graded using MRI, histologic and biochemical examinations of the menisci were then performed. Comparative analyses of MRI grading and results of histological/biochemical examinations of the menisci were performed in each group. In addition, comparative analyses of histological/biochemical conditions were performed between specimens of the study group and the control group showing grade 0 on MRI.

Results: All specimens from the control group showed grade 0 on MRI and their histology was also grade 0. In addition, no significant differences in biochemical results were observed among the specimens of the control group. In the lateral meniscus from the study group showing degeneration on MRI it was found that the water and proteoglycan contents increased with increasing grade of degeneration whereas the collagen content decreased. The meniscus specimens of the control group and the study group showing grade 0 on MRI had similar histologic findings but had different biochemical properties. The grade I, II degenerations on MRI were not well matched with the histologic findings in the study group.

Conclusions: Severities of meniscus degeneration on MRI did not well reflect the histologic findings of the meniscus. This finding may be due to the water content of the meniscus. The factors of the high signal intensity of the degenerated lateral meniscus on MRI may be due to the decreased component of collagen and increased proteoglycan. Our findings suggested that caution should be taken when the severities of meniscus degeneration on MRI are attributed to histologic severities of degenerated meniscus.

P422

OPEN WEDGE HIGH TIBIAL OSTEOTOMY WITH BONE MARROW DERIVED MESENCHYMAL STEM CELL FOR MEDIAL KNEE OSTEOARTHRITIS

C. Whanyong[1]

[1]University of Catholic Kwandong , International St. Mary's Hospital, Incheon, South Korea

Objectives: To analyze the results of isolated autologous bone marrow derived mesenchymal stem cell (MSC) transplantation in conjunction with multiple drilling and medial opening-wedge high tibial osteotomy (HTO).

Material & Methods: Thirty knees in 29 patients with medial uni-compartmental osteoarthritic knee with genu varum were allocated to the cell-recipient group (n=15) or control group (n=15). Patients who had more than 2 compartment osteoarthritic knee joint, malalignment of the knee from femoral causes or more than 15 degree varus deformity were excluded. All patients underwent HTO and cartilage restoration procedure (multiple drilling or micro fracture). The cellrecipient group received transplantation of isolated bone marrow concentrate containing MSCs with hyaluronic biomaterial and fibrin glue whereas the control group only received microfracture alone. The primary outcome measure was International Knee Documentation Committee (IKDC) score at intervals of 3, 6, 9 months and 1 year postoperatively. Secondary outcome measures were 1-year postoperative Magnetic Resonance Observation of Cartilage Repair Tissue (MOCART) scores and secondary arthroscopic findings at implant removal surgery.

Results: Preoperatively defect size and ICRS grade were larger and more severe in the study group. Postoperatively filling up size with cartilage and recovery rate of chondral lesion were superior in the study group. Coverage size of study and control group were 4.4 ± 1.0 and 0.9 ± 0.4, and recovery rate were 79.6 ± 15.4 and 32.0 ± 20.9, respectively. ($p < 0.001$, both categories) MOCART and Koshino score were also better in the stem cell therapy group. (73.7 ± 10.4 and 51.5 ± 10.6 in MOCART and 2.8 ± 0.4 and 1.6 ±0.5 in Koshino score, $p < 0.001$, both categories) IKDC scores improved from 51.9 ± 12.3 to 81.1 ± 5.5 in the study group and 50.5 ± 12.8 to 80.2 ± 4.6 in the control group, respectively. ($p<0.001$, both groups) However there were no difference between two groups.

Conclusions: HTO and cartilage restoration procedure improved knee symptom in medial compartment knee osteoarthritic patients. And regenerative ability of chondral lesion was superior in isolated autologous bone marrow derived MSC transplantation group of patients over 50 years old.

P423

PERFORMANCE OF AN OPPORTUNISTIC SCREEN OF LOW BONE DENSITY FROM STANDARD X-RAY IN THE SINGAPORE POPULATION

C. Y. Phua[1], C. A. Syme[2], A. Bilbily[2], M. D. Cicero[2], J. Z. T. Sim[3]

[1]Ministry of Health Holdings, Singapore , Singapore; [2]16 Bit Inc, Toronto, Canada; [3]Tan Tock Seng Hospital, Singapore , Singapore

Objective: To assess the performance of an artificial intelligence opportunistic screening tool for low bone mineral density (BMD), Rho (which was validated using North American datasets with T-Scores calculated using white female references values), in patients from Singapore (where T-Scores are calculated with Singaporean reference values). We also aimed to identify the optimal Rho Score threshold to identify low BMD, with a preference for a high specificity to correctly rule-in low BMD.

Material and Methods: We identified patients at the Tan Tock Seng Hospital who had undergone a Rho-eligible x-ray (lumbar spine, thoracic spine, chest, pelvis, hand/wrist and knee) within 2020-2025 and a paired Dual-energy X-ray Absorptiometry (DXA) test within 1 year. These x-rays were retrospectively analyzed by Rho, and ground truth low BMD was determined using the lowest DXA T-Score (of lumbar spine, femoral neck or total hip) calculated with Singaporean reference values. We calculated the area under the receiver-operating characteristic curves (AUC) for the Rho Score at identifying low BMD (T-Score < -1) and identified the optimal Rho Score to yield a high specificity with reasonable sensitivity using the R package cutpointr.

Results: In 409 patients (77% female; 50-100 years of age; 72% low BMD by DXA), FRAX-Rho had an AUC of 0.85 (0.81-0.88). At a Rho Score of 7, specificity was 0.86 (0.81-0.91) and sensitivity was 0.65 (0.61-0.70).

Conclusion: Rho demonstrated high accuracy for identifying potential low BMD in Singapore patients. A score of 7 or higher should be used to flag patients as likely having low BMD. Customizing this threshold is key to optimizing device performance in different populations.

P424

MURIBACULUM GORDONCARTERI-DERIVED SAM MITIGATES RADIATION-INDUCED OSTEOPOROSIS VIA PROMOTING NUCLEOTIDE SYNTHESIS AND DNA REPAIR

C. Yu[1], R. Sun[1], S. Fan[1]

[1]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China

Objectives

Ionizing radiation (radiotherapy, spaceflight radiation, nuclear accidents) is a confirmed inducer of bone loss and osteoporosis. Improved cancer survival and deep-space exploration make radiation-induced bone injury an urgent challenge, with astronauts facing prolonged low-dose radiation risks. Mainstream treatments regulate bone metabolism broadly instead of targeting radiation-specific mechanisms. This non-specificity limits efficacy and raises long-term safety concerns, underscoring the need for targeted interventions. The "gut-bone axis" is pivotal for skeletal homeostasis, as intestinal microbiota and their metabolites modulate immunity, metabolism, and bone health. However, radiation's impact on gut microbiota and the causal link between radiation-induced dysbiosis and bone loss remain unclear, hampering microbiota-targeted therapies.

Material and Methods

Irradiated mice received FMT, with bone protection verified via microstructure and turnover markers. Fecal multi-omics sequencing (metagenomics, broad-target metabolomics, whole-genome sequencing) identified key bacteria (*Muribaculum gordoncarteri*) and metabolite (S-adenosylmethionine, SAM). Irradiated mice were administered *M. gordoncarteri* or SAM; engineered *Escherichia coli* confirmed SAM's synthesis pathway and bone-protective effect. Bone marrow stromal cells from SAM-supplemented/non-supplemented mice underwent scRNA-seq. Nucleotide metabolic sequencing, DNA damage staining, and electrophoresis evaluated nucleotide synthesis and DNA repair.

Results

FMT from healthy mice significantly improved osteoporosis in irradiated mice by boosting osteogenesis-related gene expression. Metagenomic sequencing revealed radiation altered intestinal microbial profiles, with reduced flora abundance, while supplementary *M. gordoncarteri* counteracted radiation-induced bone loss and enhanced osteogenic activity. Whole-genome sequencing of *M. gordoncarteri* indicated radiation activated its amino acid metabolism pathways. SAM was identified as the key metabolite mediating *M. gordoncarteri*'s bone protection. *M. gordoncarteri* expresses the *metK* gene to produce synthetase, catalyzing methionine conversion to SAM—gastrointestinal supplementation of *metK*-engineered *Escherichia coli* effectively prevented radiation-induced osteoporosis. The scRNA-seq showed radiation caused DNA damage in osteogenesis-related cells, which SAM reversed by activating DNA repair pathways. Nucleotide metabolism sequencing confirmed SAM promoted nucleotide synthesis in these cells, enhancing DNA repair against radiation damage. Clinical data linked intestinal microbiota changes, SAM levels, and radiation-induced bone mineral density alterations.

Conclusion

This study confirms gut microbiota mediates radiation-induced osteoporosis, identifying *M. gordoncarteri*-derived SAM as a key bone protector. SAM mitigates osteoblast DNA damage via enhancing nucleotide synthesis and DNA repair, clarifying the gut-bone axis' role in radiation exposure. The protection of *M. gordoncarteri* and SAM suggests broader systemic radioprotection potential, and clinical-preclinical consistency strengthens translation for radiotherapy patients and astronauts.

OSTEOBLASTIC 11B-HSD1-MEDIATED LOCAL GLUCOCORTICOID REACTIVATION DRIVES GLUCOCORTICOID-INDUCED OSTEOPOROSIS

C. Z. Chuanxin[1], X. L. Xinyi[1], Y. Q. Yonghua[1], H. L. Hongrui[1], N. L. Nanxi[1], X. W. Xiaoxin[1], Z. L. Zhanghao[1], C. Z. Chuanyi[2], B. C. Bin[2], A. L. Aiping[1], G. Z. Ge[1], J. L. Jin[1]

[1]Hong Kong Baptist Univerisity, Hong Kong, China; [2]The First Affiliated Hospital of Shantou University Medical College, Shantou, China

Objective:
Glucocorticoid-induced osteoporosis (GIOP) is a major clinical challenge, yet the contribution of local glucocorticoid (GC) metabolism to skeletal toxicity remains poorly understood [1, 2]. 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) amplifies GC signaling locally by converting inactive GCs to their active forms [3]. In our previous work, we showed that osteoblastic 11β-HSD1 mediates bone loss under metabolic stress [4]. In this study, we aimed to determine whether local GC reactivation driven by osteoblastic 11β-HSD1 contributes to bone loss in GIOP.

Methods:
A GIOP model was established in mice via oral corticosterone (CORT, 100 ug/ml) administration for 4 weeks. Bone microarchitecture and formation were quantified by micro-CT and dynamic histomorphometry. Systemic GC profiles were analyzed by ELISA, while local GC activation was assessed via gene expression of *11β-HSD1* and the GC-responsive gene *Gilz*. Osteoblast-specific 11β-HSD1 knockout mice (Bglap-Cre; Hsd11b1$^{flox/flox}$, CKO) were generated to evaluate the functional contribution of osteoblastic 11β-HSD1 to GC-induced bone loss.

Results:
CORT administration induced severe trabecular bone loss (BV/TV $p<0.05$ vs. vehicle, Fig. 1a) and marked suppression of bone formation (MAR: $p<0.05$ vs. vehicle, Fig. 1b). Although circulating levels of active GC (CORT) were unchanged (Fig. 1c), serum levels of inactive GC (11-dehydrocorticosterone) were significantly increased ($p<0.05$, Fig. 1d), indicating a dissociation between systemic GC exposure and skeletal damage. In contrast, bone tissue showed marked activation of local GC signaling, with significantly upregulated *Gilz* (GC-responsive gene, Fig. 1e) and *Hsd11b1* (Fig. 1f) expression (both $p<0.05$). Immunofluorescence confirmed that 11β-HSD1 was predominantly expressed in osteocalcin-positive osteoblasts rather than CTSK-positive osteoclasts (Fig. 1g), supporting the presence of osteoblast-localized GC reactivation. Importantly, osteoblast-specific deletion of 11β-HSD1 effectively protected against CORT-induced trabecular bone loss (Fig. 2). While WT mice showed significant reductions in BMD ($p<0.01$), BV/TV ($p<0.05$), and trabecular thickness (Tb.Th, $p<0.01$), these parameters were preserved in knockout mice (all $p>0.05$), supporting a causal role of osteoblastic 11β-HSD1 in mediating GC-induced bone toxicity.

Conclusion:
Our findings identify osteoblastic 11β-HSD1–mediated local GC reactivation as a key contributor to GC-induced bone loss. Targeting osteoblastic 11β-HSD1 may offer a bone-selective strategy to prevent GIOP.

PAIN CHARACTERISTICS AND CLINICAL ASSOCIATIONS IN MULTIPLE MYELOMA

C. Zayani[1], Z. Gassara[1], A. Farah[1], M. Ezzeddine[1], A. Feki[1], S. J. Ben Jmeaa[1], M. Kallel[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction:
Pain is a common and debilitating symptom in multiple myeloma (MM), resulting from structural bone lesions or neurological complications. It can be classified as nociceptive, neuropathic, or mixed. This study aimed to characterize pain patterns and their clinical associations in patients with MM.
Methods:
We conducted a retrospective study of MM patients. Pain was classified as nociceptive, neuropathic, or mixed; patients with mixed pain were excluded from comparative analyses. Data on pain intensity (VAS), MRI findings, and treatments were collected. Statistical significance was set at $p < 0.05$.
Results:
The study included 55 patients. Bone pain was the most common presenting symptom, reported in 48 patients (87.3%). Pain localization was predominantly lumbar (n = 20, 36.4%), followed by thoracic (n = 12, 21.8%), cervical (n = 8, 14.5%), long bones (n = 3, 5.5%), and flat bones (n = 4, 7.3%). MRI revealed vertebral compression in 24 patients (43.6%), multiple vertebral lesions in 29 (52.7%), spinal cord compression in 9 (16.4%), epiduritis in 8 (14.5%), and fractures in 5 (9.1%). Bone involvement per CRAB criteria was present in 49 patients (89.1%). Pain was classified as nociceptive in 25 patients (45.5%), neuropathic in 21 (38.2%), and mixed in 9 (16.4%). Mean VAS was 6.7 ± 1.9, with 31 patients (56.4%) reporting severe pain (VAS ≥ 7). Analgesic treatment included non-opioids (n = 9, 16.4%), weak opioids (n = 16, 29.1%), and strong opioids (n = 25, 45.5%); 5 patients (9.1%) received palliative radiotherapy. Pain mechanisms were significantly associated with MRI findings: nociceptive pain was more frequently linked to structural lesions (multiple lesions 52% vs 38.1%, p = 0.047; vertebral compression 40% vs 23.8%, p = 0.002), whereas neuropathic pain was associated with neurological complications (spinal cord compression 23.8% vs 0%, p = 0.001; epidural involvement 19% vs 0%, p = 0.001). No significant difference in pain intensity was observed between nociceptive and neuropathic pain (p = 0.49).
Conclusion:
Pain in MM is common and heterogeneous, with nociceptive pain primarily associated with structural bone involvement and neuropathic pain linked to neurological complications. Recognizing pain mechanisms can guide targeted management and improve patient care.

P427

OSTEOPOROSIS AND HEARING LOSS: NATIONWIDE EVIDENCE FOR AN EXTRA-SKELETAL PROTECTIVE EFFECT OF ZOLEDRONIC ACID AND DENOSUMAB

C.-F. Huang[1], S.-H. Hung[2], W. P. Chan[3]

[1]Department of Family Medicine, Chi Mei Medical Center, Tainan City, Taiwan; [2]Department of Otolaryngology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [3]Department of Radiology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Objective
To investigate the association between osteoporosis or fragility fractures and the risk of hearing loss, and to evaluate whether long-acting injectable osteoporosis treatments, specifically zoledronic acid and denosumab, are associated with a reduced risk of hearing loss.
Material and Methods
This nationwide retrospective cohort study used data from Taiwan's National Health Insurance Research Database between January 2011 and December 2020. Adults aged ≥50 years with a diagnosis of osteoporosis or fragility fractures were identified and compared with matched controls without these conditions. Propensity score matching was performed using age, sex, and Charlson Comorbidity Index. A second matched cohort compared patients treated with zoledronic acid or denosumab with untreated individuals. Incident hearing loss was the primary outcome. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazards models, with subgroup and sensitivity analyses conducted to assess sex differences and treatment duration effects.
Results
Individuals with osteoporosis or fragility fractures had a significantly higher risk of hearing loss compared with matched controls (adjusted HR 1.36, 95% CI 1.33–1.38). Among affected individuals, treatment with zoledronic acid (HR 0.87, 95% CI 0.81–0.93) or denosumab (HR 0.91, 95% CI 0.85–0.97) was associated with a significantly lower risk of hearing loss compared with no treatment. Subgroup analyses demonstrated that zoledronic acid was protective in both sexes, whereas the association for denosumab reached statistical significance only in males. Sensitivity analyses indicated that treatment durations of 2–4 years were associated with the greatest risk reduction.
Conclusion(s)
Osteoporosis and fragility fractures are associated with an increased risk of hearing loss. Long-acting injectable osteoporosis therapies, particularly zoledronic acid, are associated with a reduced risk of hearing loss, suggesting a potential extra-skeletal benefit beyond fracture prevention.

RE-VALIDATION OF THE FRACTURE RISK ASSESSMENT TOOL (FRAX®) IN TAIWAN: TWO COHORTS WITH TEN- YEAR FOLLOW-UP STUDY

C.-C. Li[1], I.-T. Liu[2], F. W. Liang[3], Y.-F. Chang[4], C.-S. Chang[4], Z.-J. Sun[4], S.-H. Fu[5], C.-Y. Li[6], L.-C. Kuo[7], C.-H. Wu[8]

[1]Institute of Allied Health Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [2]Department of Family Medicine, E-DA Hospital, Kaohsiung, Taiwan; [3]Department of Public Health, College of Health Science, Kaohsiung Medical University, Kaohsiung, Taiwan; [4]Department of Family Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [5]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [6]Department of Public Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [7]Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [8]Institute of Gerontology, Medical College, National Cheng Kung University, Tainan, Taiwan

Objective

The Fracture Risk Assessment Tool (FRAX®) is widely employed in Taiwan to estimate the 10-year probability of osteoporotic fractures. However, its predictive validity has not been comprehensively evaluated in this context. This study aims to examine the real-world performance of the FRAX® algorithm in estimating 10-year fracture risk among Taiwanese adults and to determine clinically relevant risk thresholds based on local epidemiological data.

Material and Methods

The data was obtained from two community cohorts established in Taiwan between 2009 and 2010, comprising 1,976 individuals aged 40 years or older. Participants were followed for up to 10 years through linkage with the National Health Insurance Research Database. Ten-year fracture probabilities for major osteoporotic fractures and hip fractures were calculated using Taiwan-specific FRAX models with and without femoral neck bone mineral density (BMD). Receiver operating characteristic analyses were conducted to define optimal intervention thresholds.

Results

During follow-up, 213 participants (10.8%) sustained major osteoporotic fractures (MOF), and 93 (4.7%) experienced hip fractures (HF). In contrast, the model incorporating bone mineral density tended to underestimate fracture occurrence, particularly in older adults. The locally derived fracture prevention risk thresholds, 9.0%~9.1% for MOF and 4.5%~4.7% for HF in FRAX without BMD, provide the most appropriate balance between sensitivity and specificity (Youden index) compared to international reference values and provide evidence-based support for further DXA scans.

Conclusion

FRAX remains a useful fracture risk assessment tool in Taiwan; however, its intervention threshold varies depending on whether BMD is included and the local prevalence of osteoporosis. Re-calibrated thresholds may enhance risk stratification and support more effective fracture prevention strategies in Taiwanese populations.

P430

SINGLE DOSE OF ZOLEDRONATE AFTER HIP AND VERTEBRAL FRACTURE ON LONG-TERM MORTALITY: A REAL-WORLD EVIDENCE STUDY

C.-H. Wu[1], C.-C. Li[2], Y.-F. Chang[3], C.-A. Shih[4], S.-H. Fu[5], T.-W. Tai[4]

[1]Institute of Gerontology, Medical College, National Cheng Kung University, Tainan, Taiwan; [2]Institute of Allied Health Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [3]Department of Family Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [4]Department of Orthopedics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [5]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan

Objective

Randomized trials have demonstrated that single dose of zoledronate administration can reduce ten-year fracture risk in low-risk, early postmenopausal women. Whether a single dose of zoledronate confers long-term survival benefits after major osteoporotic fractures in real-world practice is unknown. This study aims to evaluate the association between single-dose zoledronate use and long-term all-cause mortality among patients hospitalized for hip or vertebral fractures in Taiwan.

Material and Methods

We conducted a nationwide retrospective cohort study (n=349,098,455) using Taiwan's National Health Insurance Research Database from 2009 to 2021. Patients hospitalized for a first hip or vertebral fracture and with no prior anti-osteoporosis medication were identified. Individuals who received a single dose of zoledronate were compared with those who received no anti-osteoporosis treatment. A 1:4 propensity score matching was performed based on age, sex, and Charlson Comorbidity Index. Participants were followed until 2022, and mortality risk was analyzed using Cox proportional hazards models.

Results

After matching, a total of 14,261 fracture patients (zoledronate = 2853) were included (mean age 77.6±10.0 years; 73.4% female). The baseline characteristics were well balanced between two groups. After a ten-year follow-up, mortality occurred in 46.7% of patients receiving a single dose of zoledronate and 50.0% of untreated patients. Subjects with osteoporosis fracture received the zoledronate usage were associated with a significantly lower risk of all-cause mortality (HR 0.93, 95% CI 0.87-0.99, p<0.05).

Conclusion

In this nationwide real-world study of older patients with osteoporotic fracture, a single dose of zoledronic acid was associated with lower ten-year mortality. These findings extend evidence from randomized trials to routine clinical practice and support the potential survival benefit of early zoledronate treatment after hip and vertebral osteoporotic fractures in Asian populations, even just a single dose.

P431

ANALYSIS OF IMMEDIATE POOR OUTCOMES AFTER KYPHOPLASTY IN TREATING OSTEOPOROTIC THORACOLUMBAR SPINAL FRACTURE WITH SINGLE SPINEJACK TO DEVELOP THE STRATEGY FOR CONDUCTING KYPHOPLASTY

C.-J. Hsu[1]

[1]DEPARTMENT OF ORTHOPAEDICS / KAOHSIUNG VETERANS GENERAL HOSPITAL, KAOHSIUNG, Taiwan

Introduction:
Unsatisfied outcomes were not uncommon even though kyphoplasty might achieved immediate relief of symptoms for osteoporotic thoracolumbar fractures with less invasiveness. We intended to develop a strategy for conducting kyphoplasty by reviewing those patients with poor results after kyphoplasty.
Methods: We conducted kyphoplasty by applying single Spinejack into fractured vertebra for 45 patients from January 2022 to December 2024. We usually chose the more collapsed side for placing the Spinejack by examining the pre-operative MR images if the pedicle was not fractured. We routinely started cement injection through the Spinejack with following supplement of cement according to the distribution of cement filling under intermittent fluoroscopy. We usually stopped cement injection as the pre-operative plan.
Results: The average SF-36 score improved from 52 to 81 in the follow-up. Six patients among 45 patients reported dissatisfaction outcomes immediately after kyphoplasty. There were 3 patients with cement leakage and 3 patients with neglected fractures or nearly united fracture by radiological diagnoses. However, they included 5 patients complaining of worse back pain and one patient remaining as painful as pre-operative status. Limited amount cement into nearly united vertebral fracture was attributed for the patient with back pain as pre-operative status. The neglected fractures were treated by another vertebroplasty/ kyphoplasty. The patients with cement leakage were treated conservatively in consideration of no post-operative neurological symptoms.
Conclusion: Pre-operative MRI should include a sagittal view of whole spine to prevent neglected fracture and nearly united fracture. More attention should be paid to fresh vertebral fractures that fracture comminution could cause higher possibility of cement leakage. Postponing kyphoplasty by one to two weeks should be considered to decrease development of cement leakage for new vertebral fracture.

P432

THE SATISFACTORY CLINICAL OUTCOMES WITH LIMITED COMPLICATION JUSTIFIED THE SURGICAL TREATMENT OF FRAGILE PELVIC FRACTURE FOR PATIENTS OLDER THAN 80 YEARS

C.-J. Hsu[1]

[1]DEPARTMENT OF ORTHOPAEDICS / KAOHSIUNG VETERANS GENERAL HOSPITAL, KAOHSIUNG, Taiwan

Introduction: Conservative treatment was previously preferred for older patients with fragile pelvic fractures in consideration of anesthetic risks. However, medical complications commonly developed because of bed-ridden status and co-morbidities. We therefore investigated the clinical outcomes of patients older than 80 years with fragile pelvic fractures to assess the feasibility of surgical treatment.
Methods: We explored the clinical database of our hospital to search for patients who were operated due to pelvic fractures from 2022 to 2024. We collected patients older than 80 years with intra-operative hemodynamics and postoperative follow-up at least one year. Seventeen patients with mean age of 83.9 ± 2.95 years were enrolled that were 6 male and 11 female patients. The majority of patients were classified as ASA III (68.8%) and ASA II (25.0%). Charlson Comorbidity Index (CCI) assessment revealed that 43.8% of the patients had at least one preexisting comorbidity. The most common injury mechanism was a minor trauma that fell from a standing or sitting height. Regarding surgical treatments, 7 patients were operated with plate fixation and 10 patients were operated with TITS screws with or without anterior column fixation.
Results: Even though the average operative time was 3.16±1.90 hours, most of time was spent in fracture reduction under guide of c-arm intensifier. Ten patients needed no blood transfusion during operations. But, seven patients with plate fixation had average blood transfusion of 1254.3 ml. Among the 17 patients, 14 patients (93.3%) achieved bony union by 6 months post-operative. However, one patient developed loss of reduction that did need further operation but pain medication. No additional operation was performed for complications throughout the whole course of follow-up. Fourteen patients with bony union discontinued pain medication by one month post-operative. The other 3 patients continued occasional analgesic medication during the follow-up. Fifteen patients reported recovery of previous activity level by one year post-operative.
Conclusion: Elderly patients even older than 80 years undergoing surgical fixation for fragile pelvic fractures could achieve timely bony union as usual. Besides, almost 90% of 17 patient restored their previous activity level by one year after operations without continuation of pain medication. Surgical treatment deserved a recommendation for elderly patient with fragile pelvic fractures that caused limited complication.

P433

DESCRIPTIVE STUDY OF OSTEOPOROSIS IN MEN MANAGED IN A FRACTURE LIAISON SERVICE (FLS)

C.-O. Sánchez González[1], J.-S. Cruz[1], A.-P. Mozo[1], E. De la Huerga[1], M.-T. Navio[1], L. Lojo[1], L. Cebrian[1], C. Marín[1], A. Román[1], E. Calvo[1], P. Cardoso[1], M.-F. Del Pino[1], C. Siso[1], A. Pareja Martínez[1]

[1]Hospital Universitario Infanta Leonor, Madrid, Spain

Background: Osteoporosis in men remains a largely under-diagnosed and under-treated condition. Although the incidence of fragility fractures is lower in men than in women, post-fracture mortality, particularly following hip fracture, is substantially higher. FLS units have proven effective in improving the identification and management of osteoporosis; however, data focused on male population is still limited.
Objective: To describe the cohort of men with osteoporosis managed in our FLS between 2022 and 2025.
Methods: A descriptive cross-sectional study of men with established osteoporosis, defined as a history of fragility fracture, managed at a multidisciplinary fracture prevention unit (Fracture Liaison Service, FLS).

Risk factors, secondary causes of osteoporosis, number and anatomical location of fractures, age at first fracture, and treatments received were analyzed.

Results:

A total of 70 men were included.
The mean age of the cohort was 76.8 ± 12.8 years.
The most frequent fractures were hip fractures (31%), followed by vertebral fractures (29%).Fifteen percent of patients had proximal humerus fractures, 13% distal radius fractures, and 12% fractures at other locations.
Overall, 34% of patients had sustained more than one fragility fracture.
The mean age at first fracture was 73 ± 13 years.
A history of tobacco use was present in 80% of the cohort (current or former smokers), and alcohol consumption was reported in approximately one-third of patients. Other significant risk factors included physical inactivity (65%), diabetes mellitus (32%), and chronic kidney disease, with 27% of patients exhibiting a glomerular filtration rate ≤45 mL/min/1.73 m².
Secondary osteoporosis was identified in 9% of patients due to chronic corticosteroid therapy and in 6% due to hypogonadism or hormonal suppression.
Following evaluation by the Fracture Liaison Service (FLS), pharmacological therapy was initiated in 98% of patients.
Denosumab was the most frequently prescribed agent (43%), followed by zoledronate (23%), oral bisphosphonates (20%), teriparatide (12%), and romosozumab, administered off-label in a single patient.
Calcium and/or vitamin D supplementation was reported in 95% of the cohort.

Conclusions:
Tobacco use and sedentary lifestyle were the most commonly identified modifiable risk factors. Hip and vertebral fractures were the predominant fragility fractures, collectively accounting for approximately two-thirds of all fracture events. Fractures traditionally frequent in women, such as distal radius (Colles) and proximal humerus fractures, were less prevalent in this cohort.
Denosumab and zoledronate were the primary therapeutic choices in 66% of patients, with relatively low prescription of oral bisphosphonates and teriparatide compared to their widespread use in pre- and postmenopausal osteoporosis.
However, studies with greater methodological rigor are required to reinforce our findings

DESCRIPTIVE ANALYSIS OF PATIENTS MANAGED IN A FRACTURE LIAISON SERVICE FROM MARCH 2019 TO OCTOBER 2025. SIX YEAR FOLLOW-UP

C.-O. Sánchez González[1], A.-S. Pareja Martínez[1], J.-S. Cruz[1], L. Lojo[1], L. Cebrian[1], A. Román[1], C. Marín[1], E. Calvo[1], P. Cardoso[1], M.-F. Del Pino[1], C. Siso[1], E. De la Huerga[1], M.-T. Navio[1], A.-P. Mozo[1]

[1]Hospital Universitario Infanta Leonor, Madrid, Spain

Background
Fracture Liaison Services (FLS) are multidisciplinary care models aimed at secondary prevention of fragility fractures in patients over 50 years. By providing coordinated post-fracture management, FLS have demonstrated high clinical and cost-effectiveness in reducing subsequent fracture risk.

Objective
To characterize the demographic, clinical, and therapeutic profile of patients with osteoporosis managed in our hospital's FLS over a six-and-a-half-year period.

Methods
We conducted a retrospective observational study of patients ≥50 years with fragility fractures attended in our FLS between March 2019 and October 2025. Data were extracted from electronic medical records, including demographics, fracture history, pharmacological management, supplementation, adherence, and incident fractures. Results are reported as mean ± SD or percentages.

Results
A total of **1,431 patients** were included (mean age 76 ± 9 years; 84% female). **Thirty percent** had a prior fracture, and only **17%** were receiving osteoporosis-specific therapy before FLS enrollment.
Index fracture sites were: **hip** 38% (n=557), **distal radius** 19% (n=297), **vertebra** 17% (n=251), **humerus** 16% (n=237), and **other sites** 9.6% (n=141).
Post-FLS intervention, **83% of patients initiated osteoporosis therapy**: **denosumab** 44% (n=495), **oral bisphosphonates** 31% (n=352), **teriparatide/abaloparatide** 12% (n=138), **zoledronate** 9.8% (n=110), **romosozumab** 2.2% (n=27), **raloxifene/bazedoxifene** 0.1% (n=2).
Supplementation was provided as follows: **vitamin D** 89.5%, **oral calcium** 64.5%. During follow-up, **32 incident fractures** were reported (2.2%), with **treatment adherence exceeding 65%**.

Conclusions

- Fragility fractures predominantly affect women, with **hip fractures** being most common, followed by **distal radius fractures**.
- A substantial proportion of patients had a prior fracture, yet the majority were untreated before FLS enrollment.
- **Denosumab** and oral bisphosphonates were the most frequently prescribed therapies.
- High adherence and a low rate of incident fractures indicate effective secondary prevention.
- Our FLS demonstrates that a **multidisciplinary, coordinated approach** effectively reduces fracture risk through optimized therapy initiation, adherence monitoring, and risk factor management.
- FLS represent an effective model for secondary prevention of fragility fractures in clinical practice.

LOW BONE MINERAL DENSITY AS A POTENTIAL PREDICTOR OF RECURRENT STROKE AND PNEUMONIA IN PATIENTS WITH STROKE: A HOSPITAL-BASED STUDY

C.-S. Hsu[1], Y.-J. Liao[2]

[1]Department of Physical Medicine and Rehabilitation, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Department of Pharmacy, Taichung Veterans General Hospital, Taichung, Taiwan

Background

Patients with stroke are at high risk of recurrent stroke and pneumonia. Low bone mineral density (BMD) is prevalent after stroke, but its prognostic value for these adverse outcomes has not been fully established. We aimed to investigate the correlation between BMD and risks of recurrent stroke and pneumonia among stroke patients in a Taiwanese cohort.

Material and Methods

In this single-center retrospective cohort study, 905 patients with stroke from a hospital-based database in Taiwan (2000-2022) were included. Patients were stratified by femoral and lumbar spine BMD. Recurrent stroke and pneumonia were the primary and secondary outcomes, respectively. Cox proportional hazards regression was performed to assess the associations between BMD and outcomes.

Results

Stroke patients with lower femoral BMD had a significantly increased risk of recurrent stroke, particularly when femoral BMD was below 0.723 g/cm² (HR = 1.423, p = 0.032). In contrast, lumbar spine BMD was not significantly associated with recurrent stroke (HR = 0.963, p = 0.815). Regarding secondary outcomes, lower lumbar spine BMD was significantly associated with an increased risk of pneumonia, whereas femoral BMD showed no significant association with pneumonia.

Conclusions

Low bone mineral density, particularly at the femur, was independently associated with an increased risk of recurrent stroke in patients with stroke. In addition, low lumbar spine BMD was significantly associated with pneumonia. These findings suggest that BMD assessment may provide useful prognostic information and underscore the importance of bone health management in stroke care.

SUSTAINED DENOSUMAB USE IS ASSOCIATED WITH REDUCED OSTEOARTHRITIS INCIDENCE AND LOWER RISK OF JOINT ARTHROPLASTY COMPARED WITH ONE-TIME USE: A REAL-WORLD COHORT STUDY

C.-Y. Lai[1], I.-H. Chen[2], H.-K. Yen[3]

[1]Department of Orthopedic Surgery, National Taiwan University Hospital Hsinchu Branch, Hsinchu, Taiwan; [2]Department of Orthopedic Surgery, Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan, Taipei, Taiwan; [3]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan, Taipei, Taiwan

Objectives

To evaluate whether multiple time (sustained) denosumab use is associated with a lower risk of incident osteoarthritis (OA) and subsequent joint arthroplasty compared with one-time denosumab use.

Materials and Methods

We conducted a retrospective cohort study using data from TriNetX, a global federated health research network providing access to electronic medical records from large healthcare organizations. Adults aged ≥50 years receiving denosumab were categorized into multiple time users (defined as ≥2 doses, suggestive of sustained use) and one-time users. Individuals who received other osteoporosis medications or had a diagnosis of osteoarthritis at baseline were excluded. Events of osteoarthritis or arthroplasty occurring within 225 days after the first denosumab injection were excluded to minimize immortal time bias. Propensity score matching was performed to balance baseline characteristics and potential confounders between groups. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for incident OA and OA-related joint arthroplasty over a 10-year follow-up period.

Results

After propensity score matching, 40,943 patients were included in each cohort, with baseline characteristics well balanced between groups. Sustained denosumab therapy was associated with a significantly reduced risk of overall osteoarthritis (HR, 0.43; 95% CI, 0.41–0.44), including knee OA (HR, 0.40; 95% CI, 0.37–0.44), hip OA (HR, 0.50; 95% CI, 0.45–0.55), and thumb carpometacarpal OA (HR, 0.43; 95% CI, 0.37–0.51). Continued use was also linked to lower risks of total joint arthroplasty (HR, 0.41; 95% CI, 0.32–0.52), including both total knee and total hip replacement. These findings remained consistent across multiple sensitivity analyses, with a clear dose–response pattern observed.

Conclusions

Multiple time (sustained) denosumab use was associated with a reduced risk of osteoarthritis and a lower likelihood of subsequent joint arthroplasty compared with one-time use. These findings suggest a potential protective association between sustained anti-osteoporotic therapy and joint degeneration. Prospective and mechanistic studies are needed to confirm causality and elucidate biological pathways.

ASSOCIATION BETWEEN PERIOPERATIVE INTRAUTERINE PROCEDURES AND PERIPROSTHETIC JOINT INFECTION FOLLOWING TOTAL JOINT ARTHROPLASTY: A REAL-WORLD SAFETY ANALYSIS

C.-Y. Lai[1], C.-C. Chou[2], I.-H. Chen[3], H.-K. Yen[4]

[1]Department of Orthopedic Surgery, National Taiwan University Hospital Hsinchu Branch, Hsinchu, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Orthopedic Surgery, Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan, Taipei, Taiwan; [4]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan, Taipei, Taiwan

OBJECTIVE(S) To evaluate whether undergoing minimally invasive intrauterine procedures, specifically hysteroscopy and dilation and curettage (D&C), within the perioperative period increases the risk of periprosthetic joint infection (PJI) in patients undergoing total joint arthroplasty (TJA).

MATERIAL AND METHODS We utilized the TriNetX global health research network to identify female patients aged ≥45 years who underwent primary TJA (hip or knee) and concomitant intrauterine procedures (hysteroscopy or D&C) within one year before or after the index surgery. A control cohort of TJA patients without these procedures was identified. Propensity score matching (PSM) was performed 1:1 based on age, comorbidities (including diabetes, obesity, and cardiovascular diseases), and baseline medications. The primary outcome was the incidence of PJI, defined by ICD-10 codes for prosthetic infection and CPT codes for revision surgery/implant removal, within 5 years. Kaplan-Meier survival analysis and Cox proportional hazards models were used to estimate the risk.

RESULTSAfter PSM, 1,714 patients were included in each cohort with well-balanced baseline characteristics. The cumulative incidence of PJI was 1.4% in the exposure group (intrauterine procedures) and 1.9% in the control group. Survival analysis revealed no significant difference in PJI-free survival between the two cohorts (Log-Rank p=0.281). The risk ratio was 0.75 (95% CI: 0.44-1.27), indicating no statistically significant increase in infection risk associated with perioperative intrauterine interventions. Sensitivity analyses stratified by procedure timing (preoperative vs. postoperative) yielded consistent results.

CONCLUSION(S) In this large-scale, real-world cohort study, perioperative hysteroscopy and D&C were not associated with an increased risk of PJI following TJA. These findings suggest that these common gynecologic procedures can be safely performed within the perioperative period of joint replacement without compromising orthopedic outcomes. Current practices delaying necessary gynecologic care due to theoretical infection risks may warrant re-evaluation.

P438

IMPACT OF INCREASED EXERCISE FREQUENCY WITHIN MULTICOMPONENT INTEGRATED CARE ON MUSCLE MASS AND BONE MINERAL DENSITY IN OLDER ADULTS WITH OSTEOPOROSIS: A SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL

Y.-C. Lu[1], N.-H. Sie[1,2], S.-H. Fu[3,4], C.-Y. Wang[1,5]

[1]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan; [2]Center of General Education, National Chung Cheng University, Chiayi, Taiwan; [3]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [4]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Yunlin, Taiwan; [5]Department of Pharmacy, National Taiwan University Hospital Yun-Lin Branch, Yunlin, Taiwan

Objective To investigate the effects of varying exercise frequencies within a multicomponent integrated care model on muscle mass and bone mineral density among community-dwelling older adults with osteoporosis.

MethodsThis secondary analysis of the HOPE RCT in Taiwan included participants aged ≥50 years with osteoporosis. Participants were randomized into three groups: Usual Care (UC; n=124), Osteoporosis Care (OC; n=123; guideline-based treatment), and Multicomponent Integrated Care (MIC; n=95). The MIC group received comprehensive interventions, including a progressive exercise program: once-weekly 1-hour sessions for 3 months in Year 1, escalating to twice-weekly 1-hour sessions for 6 months in Year 2. Skeletal muscle index (SMI) and bone mineral density were measured using BIA and DXA, respectively, at baseline, 1-year, and 2-years. Longitudinal changes and inter-group differences were analyzed using GEE and ANOVA.

Results A total of 342 participants (300 females and 42 males; mean age 74.76 ± 8.46 years) were included. Significant differential SMI trajectories were observed in both females (p=0.031) and males (p=0.017). While SMI percentage changes showed no significant difference across groups over the full 2-year period in females (UC, −0.27±6.85; OC, 0.66±4.98; MIC, 1.00±9.22; p=0.418), a landmark analysis of the second year—during which exercise frequency increased—revealed significant group differences (p=0.017). Specifically, the MIC group (SMI +1.11%) significantly outperformed the UC group (SMI -1.20%, p=0.026). No significant difference in SMI was found between the OC and UC groups (p=0.085). Regarding BMD, significant improvements were observed at the hip (HIP) and femoral neck (FN) over the two-year follow-up in both the MIC (HIP: +1.9%, FN: +3.7%) and OC (HIP: +1.9%, FN: +2.4%) groups. In the GEE model, the MIC group showed larger improvements during the second year (HIP: B = +0.021, p < 0.001; FN: B = +0.017, p = 0.003).

Conclusion Multicomponent integrated care effectively attenuates muscle loss and increases BMD in older adults with osteoporosis. The findings highlight that the skeletal muscle and bone health benefits are more pronounced when exercise frequency is increased, underscoring the necessity of sustained and frequent physical activity in clinical care models.

P439

THE INCIDENCE OF TYPE-2 DIABETES IN PATIENTS TREATED WITH NITROGEN-CONTAINING BISPHOSPHONATES

H. P. Dimai[1], D. A. Kraus[1], W. Brozek[2], B. Reichardt[3], H. Sourij[1]

[1]Department of Internal Medicine, Division of Endocrinology & Diabetology, Medical University of Graz, Graz, Austria, Graz, Austria; [2]Agency for Preventive and Social Medicine, Bregenz, Austria, Bregrenz, Austria; [3]Austrian Social Health Insurance Fund, Eisenstadt, Austria, Eisenstadt, Austria

Objective
To investigate the risk of incident type 2 diabetes (T2D) in patients treated with nitrogen-containing bisphosphonates (N-BP) for osteoporosis care. Currently, conflicting data on the effect of N-BP on T2D incidence exists.
Material and Methods
In this nationwide retrospective cohort study, risk of T2D was evaluated in 138,858 women and 28,474 men aged 50 years and older who initiated N-BP therapy (alendronate, risedronate, ibandronate, zoledronate) between 2012 and 2021 compared to controls without N-BP therapy (416,574 women and 85,422 men). Data were based on hospital discharge diagnosis (ICD-10) and filled drug prescriptions, obtained from the Austrian Federation of Social Insurances, comprising datasets from 13 single social insurance authorities that cover approximately 98 % of the Austrian population. Cox regression models including relevant covariables (e.g. glucocorticoid use, fractures) were used and T2D defined as first prescription of an antidiabetic drug excluding insulins.
Results
Average age at study entry was 70 years. Incident T2D was significantly more frequent in N-BP users than non-users (5.63% vs. 2.73% in men (p2.3-fold in the unadjusted model (HR 2.32, 95%-CI: 2.18-2.47) to a HR of 1.47 (95%-CI: 1.37-1.57) in the fully adjusted analysis. The risk for incident T2D was highest in the first year after therapy initiation.
Conclusion
This large-scale epidemiological study provides strong evidence, that N-BP use in patients aged 50 years and older may be associated with an increased risk of T2D.

PROSPECTIVE, REAL-WORLD, OPEN-LABEL, LONGITUDINAL STUDY ON THE EFFECTIVENESS OF FIXED-DOSE COMBINATION OF NAPROXEN AND PARACETAMOL 275/325 MG/TABLET AMONG FILIPINO PATIENTS WITH OSTEOARTHRITIS, A PHASE IV STUDY

J. R. Juangco[1], D. Alagar[1], P. C. San Pedro[1], E. Brito[1], M. Saturnino[1]

[1]Philippine Orthopedic Center, Quezon City, Philippines

Corresponding Author: Jose Ronilo G. Juangco, MD ronnie.juangco@poc.doh.gov.ph

Introduction/Objectives Osteoarthritis (OA) is a prevalent degenerative joint condition that significantly impacts mobility and quality of life. This study investigates the effectiveness and safety of a fixed-dose combination of naproxen and paracetamol in reducing pain scores among Filipino patients with OA.

Methodology This observational, open-label, non-blinded phase 4 clinical trial included adult patients over 18 years old with mild to moderate OA-related pain. Participants were prescribed a fixed-dose combination of naproxen (275 mg) and paracetamol (325 mg) taken twice daily for five days. Pain scores were assessed at baseline and follow-up using a visual analog scale. Secondary endpoints included medication adherence and adverse event incidence. The Wilcoxon matched-pairs signed-rank test was used for statistical analysis.

Results A total of 67 patients participated, with a mean age of 58 years. There was a statistically significant reduction in pain scores at rest (52.9%) and during movement (45.85%) after five days ($p < 0.001$). Complete pain resolution was achieved in 31.34% of patients at rest and 10.45% during movement. The combination therapy was well-tolerated, with three mild adverse events (skin rash, abdominal pain, and palpitations), all resolving without further treatment.

Pain score	Median (IQR)		P-value
	At baseline	At follow-up	
At rest	4 (3)	2 (3)	<0.001
During movement	6 (2)	3 (3)	<0.001

Conclusion The Real-World Study showed that a fixed-dose combination of naproxen and paracetamol was effective in reducing pain associated with osteoarthritis, with early onset of pain relief and a favorable safety profile. The combination allows for lower NSAID dosing without compromising analgesic efficacy, potentially reducing the risk of adverse effects in older adults. This combination offers a promising option for managing osteoarthritis pain, providing significant analgesic benefits while minimizing the risks associated with higher doses of NSAIDs, making it particularly suitable for elderly patients.

EPHB3-KO MESENCHYMAL STROMAL CELL THERAPY RECOVERS BONE MASS IN OSTEOPOROTIC MICE

M. R. Rodríguez-Sosa[1], P. Blanco[2], R. Arévalo[2], M. Castillo[3], S. Montero-Herradón[1,2], J. García-Ceca[1,2], A. Zapata[2], D. Alfaro[1,2]

[1]Research Institute "Hospital 12 de Octubre" (imas12), Madrid, Spain; [2]Cell Biology Department, Faculty of Biological Sciences, Complutense University of Madrid, Madrid, Spain; [3]Radiology and Rehabilitation Department, Faculty of Medicine, Complutense University of Madrid, Madrid, Spain

Objective.
The present study aims to investigate the therapeutic potential of *EphB3*-deficient mesenchymal stromal/stem cells (MSCs) to improve bone condition in osteoporotic animals.
Material and Methods.
We used bilaterally ovariectomized female mice (OVX), as a murine model of osteoporosis, which were intravenously infused twice with either WT or *EphB3*-KO MSCs, at one-month interval, and analyzed one month after the last injection.
Adipose tissue-derived MSCs were isolated from a pool of 6-8 adult mice (4-6 month-old) and cultured in *Mesencult mouse MSC expansion kit* for the first week, followed by complete DMEM supplemented with FBS. Used cells were in the 3rd-4th passage of culture.
Results.
Using microCT analysis, we observed that OVX mice treated with *EphB3*-KO MSCs exhibited a bone phenotype similar to that of healthy control mice, showing higher bone volume and trabecular thickness than those treated with WT MSCs.
To check bone loss progress in the treated mice, the blood serum levels of CTX-1 (a bone resorption biomarker) and the calcium concentration in urine were quantified. Both parameters showed significantly lower values in *EphB3*-KO MSC-treated OVX mice than in OVX osteoporotic mice, thus confirming a reduction in bone loss in the former.
At the cellular level, we proved by flow cytometry that *EphB3*-KO MSC-treated animals had a higher number of pre-osteoblasts and a lower proportion of osteoclasts than untreated OVX group. This reduction in osteoclasts is likely caused by increased *Opg* gene expression and decreased *Rankl* on osteoblast-differentiating *EphB3*-KO MSCs.
Conclusion.
Based on the given results, we propose the EphB3 receptor as an important therapeutic target for treating bone pathologies, such as osteoporosis.

STATE OF THE PROXIMAL GROWTH PLATE OF THE TIBIA IN DIABETIC RATS AFTER REPEATED FRACTURE

N. Mosyagina[1], D. Astrakhantsev[1], A. Dmitrienko[1], D. Lebed[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective. The objective of the study is to test histological structure of the growth plate of the tibia in diabetic rats after repeated fracture.
Material and methods. For the purposes of the study we used HE stained sections of the proximal growth plates of the tibiae taken from 24 female diabetic rats with repeated fracture. The repeated fracture was modeled as two 2-mm round openings in the femur and the tibia made in proximal and distal metaphyseal areas. 45-day space between interventions was assigned for complete healing of the femur fracture. Non-diabetic animals with the same interventions and intact animals were used for comparison. Observation terms were 7, 15, 30 and 60 days.
Results. Diabetic animals with repeated fracture exhibited narrowing of the growth plate of the tibia as compared to non-diabetic animals with the fracture in all observation terms by 3.56%, 4.92%, 5.62%, and 7.06%. The most affected zones of the growth plate were the proliferation zone and the osteogenic zone. The proliferation zone narrowed in all observation terms by 3.97%, 5.04%, 7.82%, and 8.97%. Osteogenic zone narrowed by 5.21%, 7.37%, 7.82%, and 8.97%. Inhibition of osteogenic zone activity resulted in decrease of primary spongiosa share also in all terms – by 3.91%, 5.91%, 8.27%, and 9.32%. Unlike those of non-diabetic animals these values showed no sign of restoration.
Conclusion. In diabetic animals, repeated fracture inhibits activities of the growth plate mostly due to proliferation of chondrocytes and osteoblasts. This reduces amount of new cancellous bone and thus affects both formation and remodeling of the bone.

P443

FRACTURE HEALING AFTER BUROSUMAB TREATMENT IN AN ADULT PATIENT WITH X-LINKED HYPOPHOSPHATAEMIA (XLH) AND DELAYED FEMORAL FRACTURE CONSOLIDATION

D. Clifton Goldney[1]

[1]Instituto de Investigaciones Medicas Alfredo Lanari (Universidad de Buenos Aires), Buenos Aires, Argentina

Objective: Delayed fracture consolidation is a frequent complication in patients with XLH. Burosumab, a humanized anti-FGF23 monoclonal antibody, has shown improvement in fracture healing after 24 [(1)] 48[(2,3)] weeks in clinical trials, while evidence in adults treated with conventional therapy (CT) remains limited[(4)] .We describe a case of delayed femoral fracture consolidation treated with burosumab.

Materials and Methods:A 47-year-old woman with XLH was referred due to diaphyseal femoral pain lasting five months. She had received CT from early childhood until adolescence but discontinued treatment until symptom onset. Imaging revealed a left femoral fracture. Laboratory evaluation showed hypophosphataemia (serum phosphorus 1.9 mg/

dL; normal range 2.5–5.6 mg/dL). Quality of life (QoL) was severely impaired (WOMAC: pain 17, stiffness 8, function 55; SF-36: pain 0/100, global health 0/100). CT was initiated but limited by gastrointestinal intolerance. After six months, no improvement in pain, phosphataemia or fracture healing was observed, and burosumab was started.

Results: After six months of burosumab, despite missed doses, phosphataemia improved (pre-dose 2.4 mg/dL; post-dose 2.7 mg/dL), with marked improvement in pain and QoL (WOMAC all domains 0; SF-36 pain 100/100, global health 95/100). Bone turnover markers increased to 2.5 times the upper limit of normal for β-CTX and 2.0 times for alkaline phosphatase. The patient walked without assistive devices at month 9, and complete fracture healing was confirmed at 12 months.
Conclusion: Burosumab promoted fracture healing, improved QoL and corrected hypophosphataemia in an adult patient with a diaphyseal femoral fracture of 12 months' duration, highlighting its potential role in fracture healing in adults with XLH and the limitations of conventional therapy.

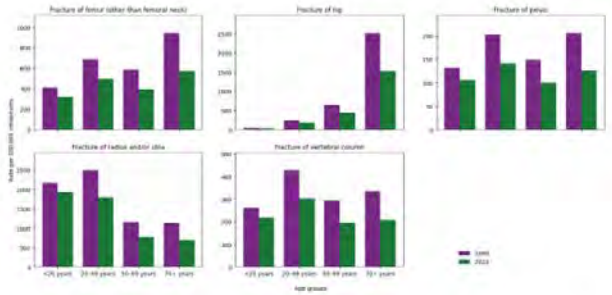
P444

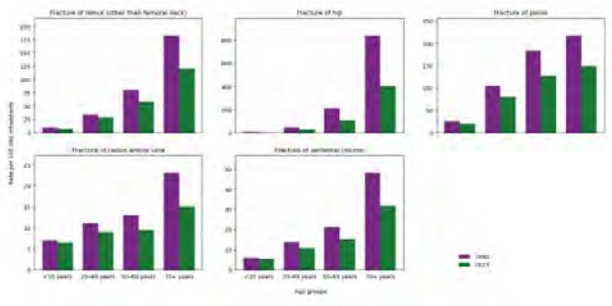
THE BURDEN OF FRACTURES IN MEXICO, 1990 – 2023: A LIFE COURSE ANALYSIS

P. Clark[1], M. J. Rios Blancas[1], D. Contreras[2]



[1]National Autonomous University of Mexico, Faculty of Medicine, Mexico City, Mexico; [2]University of Bergen, Department of Clinical Medicine, Bergen, Norway

Objective
To analyze long-term patterns and trends of fractures in Mexico and its regions from 1990 to 2023 by age group.
Material and Methods



We analyzed estimates from the Global Burden of Disease Study 2023 (GBD) produced by the Institute for Health Metrics and Evaluation, University of Washington. The GBD provides systematic and comparable estimates for diseases and injuries by age and sex across countries and, for selected locations including Mexico, at the subnational level. Fracture-related outcomes were examined nationally and across Mexican regions for the period 1990–2023 using established GBD methods.
For primary analyses, we examined fractures of the hip, vertebrae, pelvis, distal forearm, and femur. For life-course analyses, age groups were categorized as <20 years, 20-49 years, 50-69 years and >70 years.
Results
In 2023, hip fractures predominated among older adults, whereas radius and/or ulna fractures showed the highest incidence in younger and middle-aged populations. Hip fracture incidence was 1,521.6 cases per 100,000 population among adults aged ≥70 years, compared with 46.2 per 100,000 in individuals aged <20 years. Fractures of femur other than femoral neck were also more frequent in adults aged >70 years (570.2 per 100,000). Radius and/or ulna fractures reached incidence rates of 1,938.2 per 100,000 in individuals aged <20 years and 1,797.7 per 100,000 in those aged 20–49 years (figure 1a).
Years lived with disability (YLDs) due to fractures showed distinct age-specific distributions. YLD rates per 100,000 were highest for hip and pelvic fractures among adults aged ≥70 years, while distal forearm fractures accounted for a larger proportion of YLDs in younger and middle-aged groups (figure 1b).

Figure 1.

1a. Changes in age-specific incidence rates of fractures between 1990 and 2023, by fracture type

1b. Age-specific rates of years lived with disability (YLDs) due to fractures in 1990 and 2023

Conclusion
Fractures in Mexico impose an age-dependent pattern across the life course, with higher incidence at younger populations and disability increasingly concentrated in hip and pelvic fractures among older adults. Fracture incidence and YLDs increase markedly among individuals aged ≥70 years, resulting in a substantial fracture-related burden in older age groups. These patterns have important implications for health system planning and population-level fracture prevention policies in Mexico.

P445

COMPARISON OF THE EFFECTS OF INTRA-ARTICULAR PEPTIDE HYALURONIC ACID AND PRP INJECTIONS ON PAIN AND FUNCTIONAL STATUS IN PATIENTS WITH KNEE OSTEOARTHRITIS

D. R. Ozdas Sevgin[1], I. Gursoy[1], M. Guner[1], E. N. Kalayci[1], E. I. Sen[1], D. Diracoglu[1]

[1]Istanbul University Istanbul Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Istanbul, Türkiye

Objective: This study aimed to compare the effects of peptide–HA and PRP injections on pain and functional outcomes in patients with knee osteoarthritis (OA).
Materials and Methods: 62 patients aged 45–75 years with Kellgren–

Lawrence grade 2 or 3 knee OA who were admitted to the Department of Physical Medicine and Rehabilitation, Istanbul University Istanbul Faculty of Medicine, were included. Patients were randomized into two groups: the peptide–HA group (n=31), which received three intra-articular peptide–HA injections at two-week intervals, and the PRP group (n=31), which received three leukocyte-poor PRP injections at two-week intervals. Clinical assessments were conducted at baseline and at 1 and 3 months after the final injection using the Visual Analog Scale (VAS) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Within-group comparisons were performed using the Wilcoxon signed-rank test, and between-group differences were analyzed using the Mann–Whitney U test.

Results: The mean age of the patients was 56.61 ± 12.92 years, and 62.9% were female. Significant improvements in WOMAC (pain, stiffness, function) and VAS scores were observed in both groups at 1 and 3 months compared with baseline ($p < 0.001$). At the 1-month follow-up, a significant improvement in VAS rest pain was observed only in the peptide–HA group ($p < 0.001$). At 3 months, WOMAC function ($p = 0.017$) and total scores ($p = 0.021$) were significantly better in the peptide–HA group compared with the PRP group, while no significant differences were observed in other parameters.

Conclusion: Both peptide–HA and leukocyte-poor PRP injections are effective in improving pain and function in knee OA. The 3-month results suggest that peptide–HA may be more advantageous than PRP for functional improvement, while PRP remains effective for symptomatic control. Larger, long-term studies are required to confirm these findings.

P446

EFFECT OF THE SINGLE NUCLEOTIDE POLYMORPHISM A1166C OF THE AGTR1 GENE ON THE FORMATION OF COMORBIDITY ASSOCIATED WITH CARDIOVASCULAR RISK

A. Gaffarova[1], V. Beloglazov[1], E. Ageeva[1], I. Yatskov[1], D. Duryagina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to evaluate the effect of the A1166C polymorphism of the AGTR1 gene on the clinical manifestations of AS and its role in the development of comorbidity associated with cardiovascular risk.

Materials and methods: The study included 176 patients diagnosed with AS. Genotyping was carried out according to the A1166C (rs5186) polymorphism of the AGTR1 gene by the polymerase chain reaction method (PCR). The statistical analysis was carried out using the Kruskal-Wallis criterion.

Results: Patients with the AA showed a higher BASMI (AA 5.0 [4.0; 6.0] vs. AC 3.0 [3.0; 7.0] vs. CC 4.0 [3.0; 5.0], p=0.024, p1,3=0.023). Carriers of the AA had significantly lower levels of red blood cells (AA 4.7 [4.3; 5.12] vs. AC 5.29 [4.63; 5.6] vs. CC 4.57 [4.38; 4.93], p=0.025, p2.3=0.02) and platelets (AA 252 [223; 297] vs. AC 282 [236; 338] versus CC 283 [254; 333], p=0.0001, p1,3=0.001). Higher glucose values were recorded among C carriers (AA 4.8 [4.36; 5.4] vs. AC 5.4 [5.1; 5.95] vs. CC 5.4 [4.9; 5.8], p=0.0001, p1.3=0.001, p1.2=0.025). The highest triglyceride levels – for the AC (AA 1.3 [0.9, 1.7] vs. AC 1.5 [1.0; 4.1] vs. CC 0.9 [0.8; 1.2], p=0.038).

AC heterozygotes had the highest incidence of hypertension (AA 32 (37.2%) versus AC 8 (80.0%) versus CC 20 (35.7%), p1,2=0.05, p=0.025), dyslipidemia (AA 52 (53.1%) vs. AC 12 (85.7%) vs. CC 26 (46.4%), p1,2=0.012, p2,3=0.006, p=0.031). The statistically significant differences were found for grades of arterial hypertension (AH) (p=0.0001): 2nd – AA 26 (27.1%) versus AC 4 (33.3%) vs. CC 14 (24.1%), p<0.05 and 3rd – AA 0 (0.0%) vs. AC 2 (16.7%) CC 0 (0.0%), p1,2<0.001, p2,3=0.004).

Conclusion: The results obtained reveal a wide range of functions like participation in the formation of AH, the regulation of hematopoiesis, glucose and lipids levels, and the formation of comorbidity – DM, dyslipidemia, kidney pathology in patients with AS.

P447

DIFFERENTIAL ASSOCIATIONS OF PHYSICAL PERFORMANCE AND FRAILTY WITH FALLS AND MORTALITY IN OLDER ADULTS

D. G. Cetin[1], S. Z. Sahin Tirnova[1], H. Arici[1], T. Erdogan[1], S. Ozkok[1], C. Kilic[1], G. Bahat Ozturk[1], M. A. Karan[1]

[1]University of Istanbul, Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul Musculoskeletal Health Consortium, Istanbul, Türkiye

Objective:
To evaluate and compare the independent associations of physical performance and frailty with falls and all-cause mortality, and to determine whether objective performance measures provide distinct prognostic information beyond frailty assessment in older adults.

Methods
This observational study included community-dwelling older adults who underwent comprehensive geriatric assessment. Physical performance was assessed using the Short Physical Performance Battery (SPPB), with scores ≤8 indicating low physical performance. Frailty was assessed using the FRAIL scale and categorized as frail versus non-frail. Participants with incomplete physical performance or frailty data were excluded.Falls were analyzed using multivariable logistic regression, and all-cause mortality was examined using Cox proportional hazards models.

Results
This observational study included 1392 community-dwelling older adults. Baseline characteristics differed according to physical performance and frailty status (Table 1). In multivariable logistic regression analysis (Table 2), SPPB ≤8 was independently associated with falls (OR 2.03, 95% CI 1.39–2.96; p<0.001), whereas frailty was not (OR 1.20, 95% CI 0.81–1.78; p=0.367). Female sex (OR 1.40, 95% CI 1.03–1.90; p=0.031) and malnutrition (OR 1.63, 95% CI 1.20–2.22; p=0.002) were also associated with increased fall risk.
During follow-up, both SPPB ≤8 (HR 1.63, 95% CI 1.08–2.45; p=0.020) and frailty (HR 1.69, 95% CI 1.12–2.53; p=0.012) were independently associated with higher all-cause mortality in Cox regression models (Table 3). Increasing age was associated with mortality (HR 1.09 per year, 95% CI 1.06–1.12; p<0.001), while female sex was protective (HR 0.31, 95% CI 0.22–0.43; p<0.001).

Conclusions
Low physical performance was an independent predictor of falls, whereas frailty was not, indicating that objective performance measures may better capture short-term mobility-related risk. In contrast, both low physical performance and frailty were independently associated with all-cause mortality, reflecting complementary dimensions of vulnerability related to survival. Overall, these findings suggest that physical performance and frailty should not be used interchangeably and support

integrating objective functional testing alongside frailty assessment to improve geriatric risk stratification.

Table 1. Baseline Characteristics According to Falls and Mortality Status

Variable		Falls (-)	Falls (+)	p value	Mortality (–)	Mortality (+)	p value
Age, mean (SD)	Years	75 ± 7	76 ± 7	**0.016**	74 ± 7	79 ± 6	**<0.001**
Sex n (%)	Male	314 (36.8)	143 (26.5)	**<0.001**	241 (26.7)	154 (46.7)	**<0.001**
	Female	539 (63.2)	396 (73.5)		663 (73.3)	176 (53.3)	
Marital status n (%)	Single / divorced / widowed	461 (54.0)	298 (55.3)	0.65	420 (46.5)	201 (60.9)	**<0.001**
	Married	392 (46.0)	241 (44.7)		484 (53.5)	129 (39.1)

WHEN RENAL FUNCTION LIMITS MOBILITY: AN AGE-DEPENDENT ANALYSIS OF PHYSICAL PERFORMANCE IN OLDER ADULTS

D. G. Cetin[1], D. Sezer[1], T. Erdogan[1], S. Ozkok[1], G. Bahat Ozturk[1], M. A. Karan[1]

[1]University of Istanbul, Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul Musculoskeletal Health Consortium, Istanbul, Türkiye

Objective

To investigate the association between renal function and low physical performance in older adults and to evaluate age-specific differences between younger-old (60–74 years) and older- old (≥75 years) individuals.

Methods

This retrospective observational study included community-dwelling adults aged ≥60 years who underwent comprehensive geriatric assessment between 2020 and 2025. Individuals with estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m², acute illness, missing or incomplete Short Physical Performance Battery (SPPB) data were excluded. Low physical performance was defined as SPPB ≤8. Renal function was assessed using eGFR calculated by the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation, and nutritional status using the Mini Nutritional Assessment–Short Form (MNA-SF). Multivariable logistic regression analyses were performed overall and stratified by age group.

Results

A total of 380 patients were included (mean age 75±7 years, 69% female); 86 (22.6%) had low physical performance. Participants with low SPPB were older, more frequently female, and had lower eGFR, hemoglobin, albumin, and poorer nutritional status, with a higher prevalence of sarcopenia and frailty (p<0.01). In the overall multivariable model, age, female sex, sarcopenia, frailty, and lower nutritional status were independently associated with low physical performance, whereas eGFR was not significant. In age-stratified analyses, eGFR was independently associated with low physical performance in adults aged ≥75 years (OR 0.94 per mL/min/1.73 m², 95% CI 0.91–0.97; p<0.001) but not in adults aged 60–74 years.

Conclusion

Renal function becomes a clinically meaningful determinant of physical performance only in adults aged ≥75 years, when physiological reserve is critically reduced and vulnerability to mobility loss is unmasked. Importantly, in adults aged ≥75 years, renal impairment should not be viewed merely as a laboratory abnormality but as a biological signal of increased vulnerability to mobility loss, fall risk, and fracture susceptibility. Integrating renal and nutritional markers with functional assessment may enable earlier identification of high-risk older adults and support targeted interventions to preserve mobility and prevent falls and fractures.

P449

INDEPENDENT ASSOCIATIONS OF HANDGRIP STRENGTH AND CALF CIRCUMFERENCE WITH IADL AND COGNITIVE PERFORMANCE: EVIDENCE FROM THE TAIZHOU CENTENARIAN COHORT

D. Hong[1], J. Chen[1], L. Zhang[1], H. Chen[1]

[1]Taizhou Hospital of Zhejiang Province, Linhai, China

Objective: To examine associations between handgrip strength, calf circumference, and functional independence in centenarians, and to explore mediating roles of physical performance, cognition, and nutrition.
Methods: In this cross-sectional study (October–December 2025, Taizhou, China), 558 centenarians (75.3% participation rate, interviewed by 1041 volunteers) from the China Taizhou Centenarian Cohort Study were enrolled (170 men [30.5%], 388 women [69.5%]; median age 101.0 years, IQR 2.0). Standardized assessments included handgrip strength, calf circumference, 4-m gait speed, instrumental activities of daily living (IADL), cognition (AMT4), and nutrition (MNA-SF). Spearman correlations and sequential multivariable linear/logistic regression models were used, with sex-stratified and sensitivity analyses. Mediation by gait speed was assessed via attenuation of the handgrip–IADL association.
Results: Median handgrip strength was 7.5 kg (men 12.5 kg vs. women 6.5 kg, P<0.001). Handgrip strength positively correlated with IADL, AMT4, gait speed, and MNA-SF (all P<0.001). In sequential regressions, handgrip strength independently predicted IADL across models; adjusted R^2 rose from ~4% (unadjusted) to 13–15% (fully adjusted). Gait speed strongly predicted IADL and partially mediated the handgrip–IADL link. After full adjustment (sociodemographics, comorbidities), handgrip strength remained independently associated with cognition in both sexes: in men, +1 kg linked to +0.026 AMT4 points (β=0.026, 95% CI 0.000–0.051, P=0.046); in women, P<0.001. Cognition independently predicted IADL (β≈0.33, P<0.001). Calf circumference independently associated with outcomes: +1 cm linked to 18% lower IADL impairment risk (OR 0.82, 95% CI 0.76–0.89, P<0.001) and 12% lower cognitive decline risk (OR 0.88, 95% CI 0.81–0.95, P=0.002). Regular exercise was protective (OR 0.45, P<0.001); comorbidity burden was not independently significant.
Conclusion: In centenarians, handgrip strength and calf circumference are robustly and independently linked to functional independence and cognitive performance. Handgrip strength centrally connects physical, cognitive, and nutritional domains, with partial mediation by gait speed. Calf circumference offers complementary prognostic value. These findings underscore a persistent muscle–function–cognition axis at extreme age and endorse simple muscle assessments as indicators of intrinsic capacity and healthy aging.

P450

EFFECTS OF DELAYED REPAIR OF PERIPHERAL NERVE INJURY ON THE SPATIAL DISTRIBUTION OF MOTOR ENDPLATES IN TARGET MUSCLE

D. J. Deng[1], J. B. Jin[1], H. S. Han[1], G. X. Gu[1], L. D. Li[1], Z. X. Zhou[2], Y. X. Yin[1]

[1]Peking University People's Hospital, Beijing, China; [2]PLA Strategic Support Force Medical Center, Beijing, China

Motor endplates (MEPs) are important sites of information exchange between motor neurons and skeletal muscle, and are distributed in an organized pattern of lamellae in the muscle. Delayed repair of peripheral nerve injury typically results in unsatisfactory functional recovery because of MEP degeneration. In this study, the mouse tibial nerve was transected and repaired with a biodegradable chitin conduit, immediately following or 1 or 3 months after the injury. Fluorescent α-bungarotoxin was injected to label MEPs. Tissue optical clearing combined with light-sheet microscopy revealed that MEPs were distributed in an organized pattern of lamellae in skeletal muscle after delayed repair for 1 and 3 months. However, the total number of MEPs, the number of MEPs per lamellar cluster, and the maturation of single MEPs in gastrocnemius muscle gradually decreased with increasing denervation time. These findings suggest that delayed repair can restore the spatial distribution of MEPs, but it has an adverse effect on the homogeneity of MEPs in the lamellar clusters and the total number of MEPs in the target muscle.

DXA-DERIVED PROBABILITY OF HIP FRACTURE IS ELEVATED IN OSTEOSARCOPENIA AMONG COMMUNITY-DWELLING OLDER ASIAN ADULTS

D. Jha[1], M. Chandran[2], A. Praveen[1], Y. Zhou[1], P. Gupta[2], E. Lamoureux[2], N. Hong[3], Y. Rhee[3], S. Ferguson[4], B. Helgason[4]

[1]ETH Singapore SEC Ltd, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Yonsei University College of Medicine, Seoul, South Korea; [4]ETH Zürich, Zürich, Switzerland

Objective(s):
This study examined the association of a novel biomechanical marker, probability of HF (P_{Fx}), by gender and ethnicity in a multi-ethnic Singaporean cohort of community-dwelling older adults with OP, SP, and OS.
Material and Methods:
Data from 1,600 older Singaporean adults of Chinese, Indian, and Malay ethnicities were analysed from the Population HEalth and Eye Disease PRofilE in Elderly Singaporeans (PIONEER) cohort [1]. All participants underwent hip DXA scanning. OP was defined using the lowest T-score across three skeletal sites, while SP was classified according to the Asian Working Group for Sarcopenia criteria [2]. Presence of both conditions was considered indicative of OS. P_{Fx} was calculated using DXA-based finite element models (Figure 1A) [3]. High P_{Fx} risk was defined as the top tertile (≥6%), as no standard threshold exists for the marker. Age-adjusted odds ratios (OR) for high P_{Fx} were compared across conditions.
Results:
Among 722 males and 878 females (mean age 72.8 ± 8.2 years), OP showed the strongest association with high P_{Fx} (OR: 17.3 in males; 8.5 in females). SP was modestly associated with high P_{Fx} in both sexes (OR: 1.9). OS was consistently associated with elevated P_{Fx} (OR: 13.3 in males; 5.1 in females). Across all three ethnic groups, similar patterns were observed, with OP conferring the highest P_{Fx} risk, SP the lowest, and OS identifying an intermediate-to-high-risk group (Figure 1B).
Conclusions:
HF risk estimated by P_{Fx} varies according to OP, SP, and OS, with varying gender- and ethnicity-specific patterns. Osteosarcopenia consistently shifted individuals into higher P_{Fx} risk categories across sexes and ethnicities. These findings support the need for integrated musculoskeletal assessment and tailored HF risk prevention strategies

in older adults.

AGE-RELATED DECLINE IN BONE MINERAL DENSITY AND FEMORAL STRENGTH BY GENDER AND ETHNICITY IN SINGAPORE

D. Jha[1], M. Chandran[2], A. Praveen[1], Y. Zhou[1], P. Gupta[2], E. Lamoureux[2], S. Ferguson[3], B. Helgason[3]

[1]ETH Singapore SEC Ltd, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]ETH Zürich, Zürich, Switzerland

Objective(s):

This study aims to examine how age-related changes in aBMD, and S differ by gender and ethnicity in Singapore's multi-ethnic population.

Material and Methods:

We analysed data from 2,205 older adults who underwent DXA scanning from the Population HEalth and Eye Disease PRofilE in Elderly Singaporeans (PIONEER) cohort [1], comprising Chinese, Indian, and Malay participants. aBMD at the femoral neck was recorded from DXA reports. The scans were subsequently processed into finite element models to compute S. Regression models were applied to assess the relationships between age, aBMD, and S.

Results:

In this cohort, 56% were females (mean age: 73 years). Females showed a higher age-related decline in both aBMD and S than males, with a greater decline in S (Figure 1A). Malay females exhibited the greatest aBMD decline, followed by Indian and Chinese females (Figure 1B). Indian males experienced the greatest aBMD decline, followed by Chinese and Malay males (Figure 1C). Malay females had the greatest decline in S, followed by Chinese and Indian females. Chinese males showed the highest decline in S, compared to Indian and Malay males.

Conclusions:

The results suggest that rates of decline in aBMD and S vary by gender and ethnicity. While Chinese and Indian females showed similar aBMD reductions, Chinese females experienced a more pronounced decline in S. This may help explain why HF rates are higher among the Chinese females in Singapore [2]. The findings highlight the need for gender- and ethnicity-specific risk thresholds to better prevent HF in older adults.

BAASTRUP SYNDROME AS INFREQUENT CAUSE OF LOWER BACK PAIN: A CASE REPORT

D. Jovanovska-Jordanovski[1], V. Dimitrioski[1]

[1]PHI Healthcare Center Skopje, Policlinic Jane Sandanski, Skopje, North Macedonia

Introduction: Baastrup Syndrome also known as Kissing spines is a lumbar interspinous arthrosis. It's a relatively infrequent cause of lower back pain that affects elderly patients with no difference between sexes. It was first described by Christian Ingerslev Baastrup, a Danish radiologist, in 1933. Imaging findings often shows sclerosis of the contact surfaces, flattening and hypertrophy of the spinous processes (kissing spines) due

to degenerative changes of the lumbar spine.
Case report : We presented a case of a 78 year old female with chronic lower back pain subsequently increased by extension and relieved by flexion of the spine. Plain radiograph and CT findings included hyperlordosis with decreased space between adjacent spinous processes L2-L5 and reactive sclerosis of opposing interspinous surfaces also associated with intervertebral disk degeneration, spondyloarthrosis and spondylolysthesis L5-S1. Treatment was conservative, non steroidal anti inflammatory drugs to ease the pain and physiotherapy focused on stretching and strengthing exercises for abdominal and spinal muscles.
Conclusion : Baastrup Syndrome is relatively unknown cause for lower back pain that required to adequately diagnose and treat consequently.
Key words : Baastrup Syndrome, Kissing Spine, interspinosus arthrosis, lower back pain.

P454

PREVALENCE AND CLINICAL ASSOCIATIONS OF OSTEOPOROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

O. Iaremenko[1], D. Koliadenko[1], V. Dubas[2], K. Iaremenko[3], D. Fedkov[1], H. Protsenko[2]

[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]State Institution National Scientific Center named after academician M.D. Strazhesko, NAMS of Ukraine, Kyiv, Ukraine; [3]St. Michael Clinical Hospital, Kyiv, Ukraine

Objective: To investigate the prevalence and clinical associations of osteoporosis in a multicenter cohort of Ukrainian patients (pts) with systemic lupus erythematosus (SLE).
Material and Methods: A total of 121 SLE pts (aged 44 [32-54] years; 87.6% women, of whom 34.9% postmenopausal) were enrolled in three-center cross-sectional study. All pts had guideline-based indications for bone mineral density assessment and underwent dual-energy X-ray absorptiometry (DXA). Most pts (89.3%) had been exposed to glucocorticoids (GC), with a cumulative dose of 19 [10-29] g, treatment duration of 7 [3-11] years, and a current dose of 10 [10-20] mg/day prednisolone-equivalent. Disease activity and cumulative damage were assessed using SLEDAI-2K and SLICC/ACR Damage Index. Laboratory evaluation, performed contemporaneously with DXA, included erythrocyte sedimentation rate, C-reactive protein, complement C3, C4, and SLE-specific autoantibodies. Statistical analysis was performed using the chi-square test and Mann-Whitney test.
Results: Osteoporosis, defined according to WHO criteria, was identified in 34.7% of pts (postmenopausal women in 33.3% of cases). Fragility fractures were observed in 9.9% of pts. Osteoporosis was associated with longer SLE disease duration (11 [6-15] vs 6 [3-10] years, p<0.001), higher SLICC/ACR Damage Index (1 [1-2] vs 1 [0-2] points, p=0.049), greater cumulative GC dose (25 [11-32] vs 13 [6-22] g, p=0.003) and longer GC exposure (10 [6-14] vs 5 [1-10] years, p<0.001). Pts with osteoporosis had higher prevalence of nephritis (64% vs 43%, p=0.048), cardiac manifestations (59% vs 28%, p=0.003), and avascular necrosis (27% vs 4%, p=0.002). No differences were observed regarding age, sex, menopausal status, disease activity, inflammatory markers, or complement levels. Notably, anti-Sm (8% vs 33%, p=0.045) and anti-RNP (9% vs 50%, p=0.031) antibodies were less frequently detected in pts with osteoporosis.
Conclusion: In this Ukrainian SLE cohort, osteoporosis affects approximately one-third of pts and is associated with disease duration, cumulative organ damage, renal and cardiac involvement, avascular necrosis, and GC burden, whereas anti-Sm and anti-RNP positivity appears less frequent. These findings support the need for proactive bone health assessment in SLE pts.

P455

BONE HEALTH AND RISK OF FRACTURES IN FEMALES WITH OSTEOSARCOPENIA

D. Kurylo[1], N. Grygorieva[1], A. Musiienko[1]

[1]D. F. Chebotarev Institute of Gerontology, National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Objective: The study aimed to assess bone mineral density (BMD), trabecular bone score (TBS), and the 10-year probability of major osteoporotic fractures (MOF) in postmenopausal women with osteosarcopenia (OSP).
Methods: A total of 264 postmenopausal women (mean age 67.8±8.6 years) were examined and divided into three groups: the control group (without OSP or OP), the main group (with OSP), and the comparison group (with OP).
OSP was defined as a combination of sarcopenia (EWGSOP2 criteria) and 1 of the following criteria: 1) confirmed OP (BMD T-score ≤−2.5 SD) or 2) low BMD (T-score ≤−1.0 SD) plus a history of low-trauma fracture. BMD of the lumbar spine, total hip, and femoral neck, TBS, and appendicular lean mass were measured by DXA (Hologic). The 10-year probability of MOF and hip fractures (HF) was calculated using the Ukrainian FRAX® model with BMD.
Results. Regardless of the OSP criteria, the total hip and femoral neck BMDs were lower in subjects with OSP compared to OP (total hip: OSP - 0.66±0.13 g/cm² and OP - 0.73±0.09 g/cm² (criterion 1) and 0.68±0.15 vs. 0.77±0.11 g/cm² (criterion 2), respectively, p<0.0001 for both indices). TBS was significantly lower in patients with OSP than in the control group (p<0.005), without any differences compared to subjects with OP. The 10-year probability of MOF did not differ between subjects with OSP and OP, regardless of the OSP criterion, and was higher than in the control group (p<0.005 for both indices). The 10-year probability of HF in patients with OSP was higher than the similar index in subjects with OP and the control group for criterion 2, but not for criterion 1.
Conclusion. In patients with OSP, hip BMD, but not lumbar spine BMD, and TBS are significantly lower than those with OP and those in the control group. The risk of HF does not always differ between the OSP and OP groups, and this depends on the OSP criteria, which should be accounted for in clinical practice.

P456

LONG-TERM PERSISTENCE WITH DENOSUMAB – REAL-WORLD DATA

D. Lindberg[1,2], A. Spångeus[2,3], E. Baldimtsi[2,3], K. Spetz[4,5]

[1]Department of Clinical Pharmacology, Region Östergötland, Linköping, Sweden; [2]Department of Health, Medicine, and Caring Sciences, Linköping University, Linköping, Sweden; [3]Osteoporosis Outpatient Clinic, Clinical Department of Activity and Health in Linköping, Region Östergötland, Linköping, Sweden; [4]Department of Clinical Pharmacology, Region Östergötland, Norrköping, Sweden; [5]Department of Biomedical and Clinical Sciences, Linköping University, Norrköping, Sweden

Objectives The objectives of this study were to investigate persistence with denosumab 60 mg in a real-world clinical setting.
Material and Methods Patients initiating denosumab treatment at the Endocrinology clinic Linköping University Hospital between 2011 - 2020 were included. Patients were followed until 2021. Data were extracted from the local hospital database and recorded dates were assumed to represent injection dates. Persistence was defined as receiving denosumab within the recommended 6-month interval, allowing a maximum gap of 8 months between doses. Patients were classified as non-persistent at the first interval exceeding 8 months, regardless of later treatment resumption. We also calculated the proportion of doses administered within the appropriate interval.
Results 253 patients initiated denosumab treatment 2011-2020. Mean-age was 75±10 years (range 35-93 years) and 87% were women.

Across all initiation years, the 3- and 5-year persistence rates were 58% and 45% respectively. When initiation years were grouped into 2011-2016 and 2017-2020, persistence was significantly higher in the later initiation cohort (p=0.016), with 3- and 5-year persistence rates of 69% and 69%, compared with 51% and 36% in the earlier cohort. No significant differences were observed by sex or age at treatment initiation (<76 vs ≥76 years).

In total, 300, 666 and 367 injections were administered during 2011-2016, 2017-2019 and 2020-2021, respectively, with 93%, 94% and 91% administered within the defined interval of 6 + 2 months.
Conclusion A significant increase in treatment persistence was observed after 2016. This improvement is likely attributable to increased awareness of rebound effects following treatment discontinuation. In the early post-marketing period, denosumab 60 mg was more frequently discontinued after 3-5 years. More than 90% of all administered injections were given within the recommended dosing interval across all three periods.

P457

FAHR SYNDROME SECONDARY TO HYPOPARATHYROIDISM IN A PATIENT WITH CREST SYNDROME

F. Feriel[1], T. Anis[1], H. Imene[1], D. Malik[1]

[1]Mouloud Mammeri department of medicine, Tizi ouzou, Algeria

Objective
To study the association between Fahr syndrome and CREST syndrome .
Case Presentation

We report the case of a patient diagnosed with Fahr syndrome based on clinical manifestations and brain imaging findings revealing bilateral intracranial calcifications. The patient was also followed for CREST syndrome, confirmed by clinical features (subcutaneous calcinosis, sclerodactyly, Raynaud's phenomenon) and immunological findings.
The patient was a 58-year-old woman.
Past Medical History

- Menopause at the age of 50
- Post-thyroidectomy hypothyroidism since 2008, treated with levothyroxine 150 µg/day
- Follow-up for stable CREST syndrome treated with hydroxychloroquine 400 mg/day, Diltiazem 300 mg/day, colchicine 1 mg/day, and hydrocortisone 30 mg/day
- Follow-up in cardiology for aortic stenosis treated with IEC 20 mg/day and aspirin 100 mg/day
- Surgical resection of subcutaneous calcinosis of the foot in 2021

Family History

- Type 2 diabetes mellitus in one brother and two sisters
- Mother deceased from breast cancer at the age of 52

The patient had a history of total thyroidectomy in 2008 for multinodular goiter, complicated by chronic hypoparathyroidism, discovered following a tetany crisis preceded by progressive cognitive impairment, including memory and concentration difficulties.
Clinical Examination

- Conscious, cooperative patient with preserved general condition
- Able to stand and walk
- Memory and concentration impairment
- Finger paresthesia
- Muscle cramps
- Carpopedal spasm ("obstetrician's hand")
- Firm, painless subcutaneous nodules of the fingers and toes (calcinosis cutis)
- Sclerodactyly
- No other abnormalities on systemic examination

Laboratory Findings

- Severe hypocalcemia: 58 mg/L
- Hyperphosphatemia: 62 mg/L
- Parathyroid hormone (PTH): 1.2 pg/mL
- Vitamin D: 28.3 ng/mL
- TSH: 0.52 µIU/mL

Immunological tests:

- Positive ANA, speckled pattern (1:1000)
- Positive anti-TRIM21 antibodies
- Negative anti-Scl-70 antibodies
- Negative anti-centromere antibodies

Imaging Studies

- **Brain MRI**: dense, symmetrical calcifications of the basal ganglia
- **Pelvic X-ray**: multiple calcifications at tendon insertions, diffuse osteosclerosis, medial calcification

• **Hand and foot X-rays**: multiple dense nodular extra-osseous periarticular subcutaneous calcifications consistent with calcinosis cutis, with resorption of the distal phalanx of the left great toe

Discussion

The pathogenesis is primarily related to post-surgical hypoparathyroidism. The absence of PTH leads to chronic hyperphosphatemia, which, in association with hypocalcemia, promotes calcium phosphate deposition in cerebral vascular walls.

The originality of this case lies in its association with CREST syndrome. The microangiopathy characteristic of systemic sclerosis may act as an aggravating or triggering factor for both cutaneous and neurological calcifications.

This case highlights the importance of strict metabolic monitoring after thyroidectomy in patients with CREST syndrome. The occurrence of neurological symptoms should prompt evaluation for Fahr syndrome. Management is based on correction of calcium–phosphate imbalance through calcium supplementation and the use of teriparatide to stabilize lesions, as well as the crucial role of brain imaging in the presence of atypical neurological signs in patients with CREST syndrome.

Conclusion

This case report highlights a rare association between Fahr syndrome and CREST syndrome, emphasizing the importance of considering associated autoimmune diseases in the presence of atypical neurological manifestations and intracranial calcifications.

P458

METABOLIC FOOTPRINTS IN HIP FRACTURES: BIOMARKER PROFILES IN INTRA- VS. EXTRACAPSULAR INJURIES

D. Mifsut Miedes[1], J. Moreno Rivelles[2]

[1]HOSPITAL UNIVERSITARIO FRANCESC DE BORJA DE GANDIA, GANDIA, Spain; [2]CLINICA DOCTOR MORENO, VALENCIA, Spain

Objective:

To analyze the potential correlation between bone metabolism biomarkers and the type of hip fracture, distinguishing between intracapsular and extracapsular fractures.

Material and Methods:

A retrospective observational study was conducted using data from patients treated at our center between 2022 and 2023. The study included 131 patients with hip fractures who underwent blood analysis to determine levels of Vitamin D, parathyroid hormone (PTH), N-terminal propeptide of type I collagen (PINP), and beta-crosslaps (β-CTX). Fractures were classified as intracapsular or extracapsular (pertrochanteric and subtrochanteric).

Results:

Of the total patient cohort, 74 presented with intracapsular fractures and 57 with extracapsular fractures. Patients with extracapsular fractures showed significantly lower Vitamin D levels ($p<0.005$) and significantly higher β-CTX levels ($p<0.005$) compared to patients with intracapsular fractures.

Regarding PTH, higher values were observed in extracapsular fractures, although statistical significance was not reached ($p=0.108$). PINP levels were lower in intracapsular fractures, without statistically significant differences ($p=0.089$).

Conclusions:

Vitamin D and β-CTX were the biomarkers that showed significant differences between intra- and extracapsular fractures, with lower Vitamin D and higher β-CTX levels found in extracapsular injuries. PTH and PINP might reach statistical significance in studies with a larger sample size.

P459

SPECIFIC BIOMARKERS IN ANKYLOSING SPONDYLITIS RELATED WITH FUNCTIONAL STATUS

A. E. Cristea[1], D. Oprea[1], L. E. Stanciu[1], T. E. Iliescu[1], I. Calatoiu[1], M. G. Iliescu[1]

[1]Ovidius University, Constanta, Romania

Objective. There are many biomarkers described in the literature that can have an altered value in ankylosing spondylitis (AS), a chronic inflammatory rheumatic disease of unknown aetiology, but few one of these, such as IGF-1, are not as intensively studied. The main objective of this study is to monitor the therapeutic effects of a complex rehabilitation protocol on functional scales (ASDAS, BASDAI, BASMI, BASFI, SF-36) related to disease activity, pain, mobility, functionality and quality of life of these patients, as well as on serum markers such as platelets, lymphocytes, RDW, PLR, blood glucose, ESR, CRP and IGF-1.

Methods. The study was carried out in rehabilitation department from Techirghiol Balneal Rehabilitation Hospital, on 25 patients suffering from ankylosing spondylitis during a 2 week course of treatment. The patients were assessed at two time intervals, at the beginning and at the end of the treatment.

Results. The study showed statistically significant changes for BASFI score and in a limited number subscales of the SF-36 questionnaire. The analysed serum biomarkers, although some of them showed positive changes, overall there were no statistically significant changes. This study shows objectively measured improvements in patients' health status, which shows the impact of combined rehabilitation treatment.

Conclusions. More studies are needed on the effects of balneotherapy on patients with ankylosing spondylitis, on larger groups of patients, with longer follow-up periods and better validity. The effects of different types of therapeutic waters and different types of mud could also be studied to form a broader perspective.

Keywords: ankylosing spondylitis; serum biomarkers; balneotherapy

Introduction

Axial spondyloarthritis is a chronic inflammatory disease with a major impact on mobility and quality of life. The introduction of Janus kinase (JAK) inhibitors has expanded treatment options for patients with active disease who respond inadequately to conventional therapies.

Material and Method

We report the case of a 55 year old male, diagnosed with HLA B27 positive nonradiographic axial spondyloarthritis, manifesting bilateral Achilles enthesitis and high disease activity. Clinical evaluation included BASDAI and VAS scoring, spinal mobility assessment, and laboratory markers (ESR, CRP). Imaging comprised calcaneal radiography and musculoskeletal ultrasound of joints and entheses.

After an inadequate response to NSAIDs and sulfasalazine, a JAK inhibitor was initiated. Concomitantly, the patient underwent a comprehensive rehabilitation program at the Techirghiol Balneary and Rehabilitation Sanatorium, including electrotherapy, therapeutic massage and hydrokinetotherapy in saline water pools.

Results

After six months of combined pharmacologic and rehabilitation therapy, a marked clinical improvement was noted and inflammatory markers normalized. The patient regained spinal mobility and functional autonomy, reporting improved daily activity and professional performance. Oral drug administration and the integrated approach increased adherence, satisfaction and self-management awareness.

Conclusions

This case highlights the efficacy of combined JAK inhibitor therapy and personalized balneary rehabilitation in controlling inflammation, improving pain and function, and restoring quality of life in nraxSpA. The results support an interdisciplinary strategy integrating pharmacologic, physical, and educational components, underlining the importance of individualized care and patient engagement for long-term control and satisfaction.

P461

QUALITY AND RELIABILITY OF YOUTUBE VIDEOS ON SARCOPENIA EXERCISES: A CROSS-SECTIONAL EVALUATION OF ONLINE EXERCISE CONTENT FOR OLDER ADULTS

D. Ozata[1], K. Cingar Alpay[1], S. Avci[1], A. Doventas[1]

[1]Division of Geriatrics, Department of Internal Medicine, Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Türkiye, Istanbul, Türkiye

Objective

This study aimed to evaluate the quality and reliability of YouTube videos on sarcopenia exercises and to compare content characteristics according to accreditation status and target audience.

Materials and Methods

In this cross-sectional study, 50 YouTube videos identified using the keyword "sarcopenia exercise" were evaluated by three independent geriatricians using the DISCERN instrument, Global Quality Scale (GQS), and JAMA benchmark criteria. Inter-rater reliability was assessed using the intraclass correlation coefficient (ICC[2,k]). Comparisons were performed between accredited and non-accredited sources and between videos explicitly targeting older adults versus non-targeted content.

Results

The mean DISCERN score was 45.9 ± 12.0, indicating moderate overall quality. Mean GQS and JAMA scores were 3.4 ± 0.9 and 1.4 ± 0.7, respectively. Videos from accredited sources demonstrated significantly higher quality across all assessment tools (DISCERN: 53.4 vs. 42.7; GQS: 3.95 vs. 3.20; JAMA: 1.83 vs. 1.20; all $p < 0.05$). Inter-rater reliability was excellent for DISCERN (ICC = 0.965) and good for GQS (ICC = 0.88). No significant associations were observed between video duration or popularity metrics and quality scores.

Conclusion

Although exercise is fundamental to sarcopenia management, many older adults lack access to structured or supervised programs. Online platforms may therefore represent a complementary approach for delivering exercise guidance; however, the inconsistent quality of existing content highlights the need for health professional–guided, evidence-based digital exercise resources to support safe and effective geriatric care.

P462

AN EXTREMELY RARE CASE OF RIBBING DISEASE AND A PIONEERING TREATMENT SUGGESTION

D. Pafilas[1], S. Koliatzakis[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background
Ribbing disease is a rare benign sclerosing bone dysplasia. It presents with an increased bone density at the diaphysis with cortical endosteal/periosteal thickening and affects predominantly the lower extremities. The aim of this paper is to present a case of Ribbing disease and its treatment.

Case Presentation
A female 60-year-old came to our outpatient clinic presenting constant pain in the left femur and knee over the previous 3 years, with a feeling of tiredness and gradually increased heaviness. She presented limitations in walking normally; analgesic and anti-inflammatory drugs gave her little to no relief. She had been examined elsewhere and had performed xrays, CT and biopsy with no certain diagnosis. A bone scan had an increased uptake at the metaphysis of the femur. A year after she did a new bone scan with increased uptake in a larger area of the femur and was diagnosed with a benign bone lesion. Due to the persistence of her symptoms she did a Lumbar spine and left knee MRI with no findings.

At our institution new x-rays, CT and MRI were ordered.

The x-rays of her left femur presented increased bone density (sclerosis) at the metaphysis with cortical endosteal and periosteal thickening just below the lesser trochanter at medial and lateral cortex at a larger area compared to the first xrays 3 years ago. The CT scan was performed, which showed periosteal and endosteal thickening with narrowing of the intramedullary canal. In addition to the CT scan the MRI which was performed showed endosteal marrow edema and no soft tissue involvement of the lesion.

A bone biopsy was then performed from multiple spots of the sclerosis. The doctor who examined the bipsy samples concluded that the histopathological features are not specific, but in combination with the patient's history and the imaging findings, they are compatible with sclerosing diaphyseal dysplasia, of the Ribbing disease type.

A few cases have been described in which surgical reaming to remake the intramedullary canal was very effective in relieving intense pain. Suspecting Ribbing disease, we decided to apply this treatment. In addition a prophylactic nailing of the femur with a long gamma nail was decided. The main problem is performing it in a centered fashion to avoid taking a false route, fracturing the femur and making the surgical objective more complicated. As the canal was entirely occupied, it was not possible to pass a standard knotted reamer guide. The lesion area was penetrated using a sufficiently long steinmann pin to make a route under fluoroscopy. After removing the pin, a manual reamer of a larger diameter were passed sequentially on a simple guide wire until it was possible to introduce the knotted guide; this was then used to perform a standard progressive reaming, widening the canal to fit the nail.

Clinical Outcomes
One week after surgery, the patient reported no pain and she remained totally asymptomatic 6 months following the intervention.

Discussion
Ribbing disease is a rare benign pathology, characterized by endosteal/periosteal intramedullary sclerosis, principally in the lower limbs. If pain is intense, intramedullary reaming has shown to be effective in relieving symptoms. In order to avoid its recurrence we performed a nailing of the femur which will stop the disease from blocking the intramedullary canal again and cause pain. This would be considered as a permanent treatment.

P463

EFFECTS OF NEUROMUSCULAR ELECTRICAL STIMULATION ON SYSTEMIC INFLAMMATION AND MUSCLE METABOLISM MARKERS IN HOSPITALIZED OLDER ADULTS WITH CANCER: A PILOT BEFORE–AFTER STUDY

D. Pimentel[1], G. Mainardi[1]

[1]Federal University of Goias, Goias, Brazil

Objective
To evaluate whether a 5-day NMES protocol alters the neutrophil-to-lymphocyte ratio and the urea-to-creatinine ratio in hospitalized older adults with gastric or intestinal cancer.

Methods
This pilot, single-arm before–after intervention study was conducted in a public hospital in Brazil. Hospitalized older adults with gastric or intestinal cancer were evaluated according to standard hospital routines, following typical daily clinical assessments and international clinical nutrition guidelines. Patients received NMES for five consecutive days during admission to a medical ward. The NMES protocol consisted of a 5-minute warm-up at 5 Hz (pulse width 250 µs), followed by 30 minutes of stimulation at 100 Hz (pulse width 400 µs; 5 s on/10 s off). Sessions were performed twice daily with a 3-hour interval, in accordance with previously published protocols. NLR and urea-to-creatinine ratio were obtained from medical records before and after the intervention.

Results
The study included 26 patients (12 men), with a mean age of 64.28 ± 9.70 years. No significant differences were observed between pre- and post-intervention measurements. NLR values were 5.58 ± 4.86 at baseline and 6.26 ± 5.36 after NMES ($p = 0.32$). The urea-to-creatinine ratio was 37.27 ± 13.70 before the intervention and 36.38 ± 18.71 after the intervention ($p = 0.42$).

Conclusion
In this pilot before–after study, five days of NMES during hospitalization did not significantly modify systemic inflammation, as assessed by NLR, nor markers related to muscle breakdown and protein metabolism, as assessed by the urea-to-creatinine ratio, in older adults with gastric or intestinal cancer. These findings suggest that short-term NMES may be insufficient to induce measurable changes in these systemic biomarkers, supporting the need for larger controlled studies and/or longer intervention periods to clarify NMES effects during hospitalization.
Support: This study was supported by CNPq (GDP received scholarship PQ2/CNPQ).

P464

FUNCTIONAL OUTCOME OF SUBVASTUS VERSUS MEDIAL PARAPATELLAR APPROACHES FOR TOTAL KNEE REPLACEMENT IN PATIENTS WITH KNEE OSTEOARTHRITIS: A PROSPECTIVE COHORT STUDY

D. R. Aladraii[1], D. R. Abdulraof[1]

[1]king Abdullah medical city, Makkah, Saudi Arabia

Background: Subvastus approach and medial parapatellar approach are two major approaches for total knee replacement (TKR). There is no global consensus on the superiority of either approach in terms of functional outcomes.

Objective: The present study aimed to evaluate the functional outcome of TKR through subvastus approach and medial parapatellar approach by using patient-reported scores at 3-, 6-, and 12-month post-operative follow-ups.

Methods: This prospective cohort follow-up study included patients with knee osteoarthritis who underwent elective primary TKR either through the subvastus or medial parapatellar approaches at King Abdullah Medical City, Makkah city, Kingdom of Saudi Arabia, from January 2019 to December 2022. Scores from the self-reported Oxford Knee Score (OKS) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) were compared in the two groups of patients at 3-, 6-, and 12-month post-operative follow-ups.

Results: A total of 98 patients were included, of which 37 underwent TKR through the subvastus approach and 61 through the medial parapatellar approach. There was an overall significant change over time in both WOMAC and OKS scores ($P < 0.001$). Patients who underwent the subvastus approach had significantly higher mean of WOMAC and OKS than patients with the medial parapatellar approach at the 3- and 6-month follow-ups ($P < 0.05$), but not at the 12-month follow-up.

Conclusions: For TKR, the medial parapatellar approach results in better functional outcomes at the 3- and 6- month follow-up periods compared with the subvastus approach.

P465

THE CRITICAL ROLE OF FOLLOW-UP IN FRACTURE LIAISON SERVICES FOR GERIATRIC HIP FRACTURE PATIENTS: A RETROSPECTIVE COHORT STUDY

M. R. S. Israeli[1], D. R. Fisher[1], D. R. Or[2], D. R. Olshinka[2], M. R. Eilon[1], M. R. S. Israel[2], M. S. Alami[2]

[1]Hebrew University of Jerusalem, Jerusalem, Israel; [2]Hadassah Medical Center, Jerusalem, Israel

Purpose: This study aims to evaluate the impact of coordinator based FLS on medical treatment compliance and mortality in patients following hip fracture. Specifically, it seeks to evaluate the impact of routine follow-up post discharge on these outcomes.

Methods: Comparative retrospective cohort of following hip fracture patients for one year after surgery. First group with the complete FLS treatment and protocol and second group with partial FLS protocol without the routine clinical follow-up after discharge. Main clinical outcomes were osteoporosis medication compliance and morality rates.

Results: 347 participants, 182 (52.4%) without a coordinator follow-up and 165 (47.6%) with a coordinator follow-up. Patients with coordinator follow-up had better medication compliance 1 year following hip fracture (77% vs 39%). First year mortality rate was 11% and 13% accordingly without statistical significance.

Conclusion: This study found that patients in an FLS with coordinator follow-up had better clinical outcomes, receiving more timely medication recommendations and showing higher treatment adherence, highlighting the value of coordinated follow-up in long-term care

P466

DELIRIUM FOLLOWING HIP SURGERY IN COGNITIVELY INTACT POPULATION: RISK FACTORS AND IMPACT- A COHORT STUDY

M. R. Eilon[1], D. R. Fisher[1], M. R. S. Israeli[1], D. R. Or[2], D. R. Olshinka[2], M. R. Haj Yahya[1]

[1]Hebrew University of Jerusalem, Jerusalem, Israel; [2]Hadassah Medical Center, Jerusalem, Israel

Purpose: Postoperative delirium (POD) is a clinically significant complication following hip fracture surgery, yet most studies include patients with baseline cognitive impairment, making it difficult to isolate risk factors for true incident delirium. This study aimed to identify independent predictors of POD in cognitively intact older adults and to evaluate its impact on one-year mortality.
Methods: A retrospective cohort study was conducted including 674 cognitively intact patients aged ≥60 years who underwent surgical treatment for hip fractures between 2021 and 2023. Clinical, biochemical, and perioperative variables were extracted from electronic medical records. Delirium events were identified via documented diagnoses, use of delirium-directed medications, or referral for outpatient delirium evaluation. Independent predictors of delirium were determined using multivariable logistic regression. One-year mortality was assessed with Kaplan–Meier survival analysis and Cox proportional hazards modeling.
Results: Independent predictors included advanced age (OR 1.04 per year, p = 0.034), hypophosphatemia (OR 2.02, p = 0.026), hyperphosphatemia (OR 2.43, p = 0.043), chronic corticosteroid use (OR 3.38, p = 0.007), pneumonia (OR 2.43, p = 0.043), and urinary tract infection (OR 3.40, p = 0.022). Several factors, including the intensity of opioid-based pain management, affected the univariable results but were not independently associated with delirium. Delirium was associated with significantly higher one-year mortality (HR 2.38, p <0.001).
Conclusion: In cognitively intact older adults undergoing hip fracture surgery, several established and novel factors independently predicted postoperative delirium, including phosphate disturbances and chronic corticosteroid therapy. Delirium was strongly associated with increased one-year mortality, underscoring the importance of early identification and targeted prevention strategies in this population.

P467

ISOLATED ATYPICAL PEDICLE STRESS FRACTURES IN PATIENTS ON PROLONGED BISPHOSPHONATE THERAPY: REPORT OF TWO CASES AND A LITERATURE-BASED PROPOSAL FOR DIAGNOSTIC CRITERIA

D. R. Oron[1], D. R. Fisher[2], D. R. Barkay[1], D. R. Schroeder[1]

[1]Hadassah Medical Center, Jerusalem, Israel; [2]Hebrew University of Jerusalem, Jerusalem, Israel

Background/Objectives: This study reports two rare cases of isolated bilateral lumbar pedicle stress fractures in patients on prolonged BP therapy. Along with a structured literature review, the objective was to evaluate whether diagnostic criteria derived from those used for AFFs may apply to these atypical vertebral fractures.

Methods: Two patients with osteoporosis and on long-term BP therapy diagnosed with isolated lumbar pedicle stress fractures were retrospectively analyzed. A structured literature review identified similar reported cases. All cases were evaluated using the 2010 American Society for Bone and Mineral Research AFF criteria to assess applicability to isolated pedicle stress fractures.

Results: Both patients demonstrated
bilateral lumbar pedicle fractures without vertebral body involvement. One was treated conservatively; the other underwent robotic-assisted percutaneous pedicle screw fixation with documented fracture healing at six months. The literature review identified eight similar cases of isolated pedicle fractures in patients on prolonged BP therapy. Clinical course and imaging findings demonstrated stress-type features analogous to AFFs. The proposed AFF-based diagnostic criteria for pedicular insufficiency fractures were found to be applicable to all ten patients.

Conclusions: Isolated bilateral pedicle stress fractures may represent a spinal analog of AFFs. Based on shared clinical and imaging features, we propose preliminary diagnostic criteria for atypical pedicular insufficiency fractures. In creased awareness and standardized criteria may aid in early diagnosis and reporting, encouraging further studies on this rare spinal entity.

P468

BONE STRUCTURE AND MUSCULOSKELETAL DEVELOPMENT IN YOUTH ATHLETES

D. R. Kalabiska[1], D. R. Annar[1], P. D. Pal Bhattoa[2], P. D. Zsakai[3]

[1]Hungarian University of Sport Science, Research Center for Sport Physiology, Budapest, Hungary; [2]Department of Laboratory Medicine, Faculty of Medicine, University of Debrecen, Budapest, Hungary; [3]Eotvos Lorand University, Department of Biological Anthropology, Budapest, Hungary

Introduction and Purpose. In DEXA-based analyses, the use of athlete-specific reference data is essential for accurately assessing bone development in child and adolescent athletes. Our research group established new reference values for bone mineral parameters in youth athletes. The aim of the present study was to develop sport-specific reference standards for bone mineral density (BMD) and bone mineral content (BMC) across different types of athletic disciplines.
Material and Methods. Bone parameters were evaluated using DEXA in a cohort of 2,793 athletes aged 11–20 years. The bone structural parameters of each athlete were converted to z-scores relative to age- and sex-specific reference values specified by the DEXA software. Z-profile analysis and principal component analysis were used to identify body structural components in young athletes and to evaluate the associations between the identified component and the type of sport.
Results. The total BMD of male athletes is considerably higher than the age-specific references for males ($p<0.001$ in each age-group). An outstanding skeleto-muscular robusticity of male wrestlers, pentathletes and cyclers could be observed in the studied sports: wrestlers had significantly more developed skeleto-muscular robusticity and BMD than the age-group average among elite athletes, while pentathletes and cyclers had worse bone structural parameters than the reference level for their age-group among elite athletes. The corresponding trends in the BMC of female athletes are significantly higher than the references ($p<0.001$ in every age-group, with the exception of 13 years, $p= 0.04$). In case of female athletes, the rhythmic gymnasts' and pentathletes' bone structural parameters differed significantly from the players' average parameters of the studied elite athletes: their average skeletal robusticity both in the trunk and the extremities lagged behind the age-group mean values for elite athletes.
Conclusion. Youth athletes exhibited higher BMD and BMC values compared with reference values from the general population. The skeletal development of cyclers, pentathletes and rhythmic gymnasts should be monitored more frequently, since their bone development lags behind not only their age-peer elite athletes' bone development but also the population-based reference values.

P469

EARLY LUMBAR BONE LOSS IN AN ACTIVE MIDDLE-AGED MALE WITH SPINAL CORD

D. R. Pop[1], S. Deac[2], A. Gherle[2], M. Cevei[2], R. Mihut[2]

[1]University of Oradea, Faculty of Informatics and Sciences, Department of Biology, Oradea, Romania; [2]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania

Objective:
To assess the degree of bone demineralization using dual-energy X-ray absorptiometry (DEXA) in a relatively young and physically active male with spinal cord injury (SCI) who benefited from early and continuous rehabilitation.
Methods:
We present the case of a 53-year-old male with SCI following a hunting accident that resulted in a penetrating injury at the T5 level. The projectile was surgically extracted, and the patient was admitted to the "Băile Felix" Medical Rehabilitation Clinical Hospital three weeks postoperatively. Functional status was assessed using manual muscle testing (MMT), the Functional Independence Measure (FIM), and the Barthel Index at initial admission and at latest evaluation seven months later. Bone mineral density was evaluated at the last admission using a DEXA scan.
Results:
DEXA assessment revealed a lumbar spine T-score of −1.7 and Z-score -1.3(-18%) and a right hip T-score of −0.4 and Z score -0.1(-2%) consistent with osteopenia. Despite early mobilization and significant functional recovery, the lumbar T-score and Z score indicated significant bone loss. Functional outcomes improved substantially over the seven-month

period: the FIM score increased from 90 to 107 points, and the Barthel Index from 55 to 85 points. MMT of the right lower limb (most affected side) important strength gains: hip flexors improved from 2/5 to 4/5, hamstrings from 1/5 to 4/5, and knee extensors from 3/5 to 4/5. These improvements translated into enhanced ambulation, progressing from assisted walking with a rollator to independent short-distance walking and long-distance walking with a cane. Despite early rehabilitation, significant strength recovery and an active lifestyle, reduced mechanical loading following SCI in a 53-year-old male was associated with early bone loss, as evidenced by a low lumbar spine Z-score.

Conclusion: This case highlights the importance of early bone density assessment and monitoring in patients with SCI, even in those who achieve good functional recovery.

P470

SARCOPENIA IN RHEUMATOID ARTHRITIS

D. Ruci[1], V. Gjika[1], K. Serani[2], V. Ruci[3], A. Dizdari[4], E. Shkodrani[5]

[1]"Mother Teresa" University Hospital Center, Rheumatology Service, Tirana, Albania; [2]"Mother Teresa" University Hospital Center, Anesthesia-Reanimation Service, Tirana, Albania; [3]University Hospital Center of Trauma, Orthopedics Service, Tirana, Albania; [4]Memorial Regional Hospital, Orthopedics Service, Tirana, Albania; [5]"Mother Teresa" University Hospital Center, Dermatology Service, Tirana, Albania

Objective: To evaluate the presence of sarcopenia in patients with rheumatoid arthritis (RA).

Method: We conducted a study including 100 patients with RA and 100 gender-matched healthy individuals. The study aims to investigate sarcopenia prevalence in patients with rheumatoid arthritis (RA) and to detect factors associated with low muscle mass and strength. Sarcopenia was assessed using performing tests such as handgrip strength, short physical performance battery and also by determining skeletal mass index using dual photon X-ray absorptiometry (DXA).

Results: The participants comprised of 65 females and 35 males. The frequency of sarcopenia was 40% in the RA group and 8% in the control group. The prevalence was significantly different between juvenile idiopathic arthritis (JIA), spondyloarthritis (SpA), and rheumatoid arthritis (RA) groups. Results of handgrip and gait speed tests were lower in the RA group than in the healthy control group ($P = .002$ and $P < .001$, respectively). Disease activity scores were higher in patients with sarcopenia than in patients without sarcopenia. A statistically significant association was found between handgrip test results and age, gender, and disease activity.

Conclusions: Patients with rheumatoid arthritis have not only bone tissue, but also skeletal muscle tissue disorders, resulting in a significant deterioration of functional capacity and quality of life. Longer disease duration and higher disease activity may provoke the development of sarcopenia due to chronic inflammation in patients with RA. Therefore, physicians should take into account the preservative and preventive methods against sarcopenia by encouraging patients about exercise along with controlling disease activity.

P471

THE CLINICAL IMPACT OF OSTEOARTHRITIS ON THE MULTIDISCIPLINARY MANAGEMENT OF PATIENTS IN INTENSIVE CARE UNITS

D. Ruci[1], K. Serani[2], V. Ruci[3], A. Dizdari[4], E. Shkodrani[5]

[1]"Mother Teresa" University Hospital Center, Rheumatology Service, Tirana, Albania; [2]"Mother Teresa" University Hospital Center, Anesthesia-Reanimation Service, Tirana, Albania; [3]University Hospital Center of Trauma, Orthopedics Service, Tirana, Albania; [4]Memorial Regional Hospital, Orthopedics Service, Tirana, Albania; [5]"Mother Teresa" University Hospital Center, Dermatology Service, Tirana, Albania

Background:

Osteoarthritis (OA) is the most common degenerative joint disease, characterized by progressive cartilage deterioration and functional motor impairment. Although OA itself is not a direct cause for intensive care unit (ICU) admission, it represents a relevant comorbidity that significantly influences the treatment, mobilization, and recovery of critically ill patients. The aim of this study is to highlight the clinical interaction between osteoarthritis and intensive care management through the presentation of selected clinical cases.

Methods:

Three clinical cases of patients with confirmed advanced osteoarthritis admitted to the ICU for different medical and surgical reasons were analyzed. The study focused on factors complicating ICU management, including analgesia, patient positioning, mobilization, the use of anti-inflammatory medications, and recovery outcomes.

Case Reports:

Case 1: A 72-year-old woman with bilateral knee OA and obesity admitted to the ICU for severe bacterial pneumonia. Prolonged immobilization during mechanical ventilation exacerbated joint pain and stiffness, requiring early physiotherapy after respiratory stabilization and careful prevention of pressure ulcers.

Case 2: A 68-year-old man with advanced hip OA underwent total hip replacement and was transferred to the ICU due to postoperative respiratory failure. Balanced analgesia with mild opioids and early physiotherapy proved essential in minimizing postoperative complications and optimizing recovery.

Case 3: A 76-year-old woman with shoulder OA and hand deformities admitted to the ICU for acute renal failure. Difficulties in vascular access and limited upper-limb mobility complicated technical procedures, requiring close cooperation between the intensive care and orthopedic teams.

Results:

All three cases demonstrated that the presence of osteoarthritis significantly affects intensive care management, adding challenges related to positioning, pain control, and mobilization. Patients with OA showed longer ICU stays and required more extensive multidisciplinary support.

Conclusion:

Osteoarthritis should be considered an important comorbidity in critically ill patients. Pre-assessment of functional limitations, tailored analgesic therapy, and early mobilization are essential components for improving clinical outcomes in the ICU. Close collaboration among intensivists, orthopedic surgeons, and physiotherapists plays a crucial role in ensuring optimal management and recovery of patients with OA during intensive care.

UNUSUAL CASE OF RECCURENT HYPERCALCEMIA

D. S. Sidhwa[1], R. R. Reddi[2], A. D. Dutta[3], A. M. Mithal[4]

[1]Department Of Endocrinology And Metabolism, Max Super Speciality Hospital Saket, New Delhi, India; [2]Vice Chairman - Neurology Neurosciences, Neurology, Max Super Speciality Hospital, Saket, New Delhi, India; [3]Principal Consultant – Endocrinology & Diabetes, Max Super Speciality Hospital Saket, New Delhi , India; [4]Group Chairman - Endocrinology & Diabetology, Max Super Speciality Hospital Saket, New Delhi, India

Objective - Parathyroid hormone (PTH)–independent hypercalcemia represents an important diagnostic subgroup when evaluating for hypercalcemic disorders. Granulomatous disorders cause hypercalcemia through macrophage-mediated conversion of 25-hydroxyvitamin D (25-OH-D) to 1,25-dihydroxyvitamin D (1,25-OH-D). Isolated extrapulmonary sarcoidosis presenting primarily with recurrent hypercalcemia and neurological manifestations is rare.

Material and Methods - We report a case of a 77-year-old woman with a history of type 2 diabetes mellitus, prior cerebrovascular accident, surgically induced menopause, and osteoporosis with prior fragility fractures. She had two hospital admissions within one year for headache, confusion, and gait disturbance secondary to severe hypercalcemia. Contrast-enhanced MRI of the brain showed chronic lacunar infarcts and small calcified dural-based lesions consistent with meningiomas, with no acute pathology. She was lost to follow-up after the first admission.

Results- On her second presentation, the corrected serum calcium peaked at 14.3 mg/dL (8.5-10.5 mg/dl) with elevated ionized calcium and acute kidney injury. Intact PTH was suppressed, with normal serum 25-OH-D (37.85 ng/mL [30-50 ng/mL]), and mildly elevated serum 1,25-OH-D (220 pmol/L [59-159 pmol/L]). Serum phosphate, PTHrp and protein electrophoresis were normal. Inflammatory markers were elevated. Whole body FDG PET-CT showed similar FDG uptake involving the left gluteal and adjacent skeletal muscles, on both occasions, suggestive of an inflammatory process. Muscle biopsy from the gluteus maximus revealed non-caseating granulomatous inflammation with no evidence of malignancy or infection; acid-fast bacilli staining was negative. In the absence of pulmonary or systemic involvement, findings were most consistent with isolated muscular sarcoidosis causing PTH-independent hypercalcemia. After stabilisation, she was discharged on oral prednisolone 40 mg daily, and remains stable on follow up.

Conclusion - This case highlights that isolated muscular sarcoidosis can be a cause of recurrent PTH-independent hypercalcemia and emphasizes the importance of considering targeted biopsy of persistent skeletal muscle FDG uptake to establish the diagnosis.

P473

REDUCING THE TREATMENT GAP AFTER FRACTURES: HOME REHABILITATION WITHIN A FRACTURE LIAISON SERVICE (FLS)

F. Orient Lopez[1], D. Sanchez Corretger[1], C. Agudo Fernandez[1], F. Fontg Manzano[1], B. Zeballos Buscaglia[1]

[1]HU Sagrat Cor. Quironsalud. barcelona, Barcelona, Spain

OBJECTIVE

To analyse functional outcomes and treatment efficiency of fracture patients receiving home-based rehabilitation within a fracture liaison service (FLS) implemented in 2024.

MATERIAL AND METHODS

Prospective descriptive study including patients treated at home for fractures during 2024 within a newly implemented FLS. From January to December 2025, 207 fracture patients were treated at home. Variables analysed were age, sex, fracture type, Barthel Index (pre-fracture, rehabilitation admission and discharge), functional improvement (Barthel increase), and number of rehabilitation sessions. Descriptive statistical analysis was performed. Qualitative variables are presented as absolute frequency and percentage, and quantitative variables as mean and standard deviation (SD).

RESULTS

Among 1,041 patients receiving home rehabilitation, 207 (19.9%) were treated for fractures. The population consisted of 78.3% women (mean age 81.12 years; SD 9.18) and 21.7% men (mean age 74.3 years; SD 11.01). Fracture distribution was 65.2% femur, 19.3% humerus, 9,67% pelvic and 5.8% ankle fractures. Multiple fractures were present in 8,21% of patients. Mean Barthel Index was 79.05 pre-fracture, 57.90 at rehabilitation admission and 73.06 at discharge. Mean functional improvement was 15.16 Barthel points (SD 5.32), with a mean of 11.92 home rehabilitation sessions (SD 4.01).

CONCLUSIONS

Home-based rehabilitation within a fracture liaison service achieves relevant functional recovery with an efficient use of rehabilitation sessions. Integrating home rehabilitation into an FLS model contributes to closing the post-fracture treatment gap in routine clinical practice.

DOES OSTEOSARCOPENIA SYNERGISTICALLY INCREASE RISK FOR INCIDENT FALLS AND FRACTURES IN OLDER ADULTS? A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Glavas[1], J. Ryan[1], M. Ó Breasail[2], A. Gandham[3], P. Ebeling[2], J. Mesinovic[1], D. Scott[1]

[1]Deakin University, Burwood, Australia; [2]Monash University, Clayton, Australia; [3]Australian Catholic University, Melbourne, Australia

Objective: Osteosarcopenia represents the combination of low bone mineral density (BMD) and sarcopenia and has been proposed to increase the risk of falls and fractures among older adults. This systematic review and meta-analysis aimed to identify whether osteosarcopenia confers a greater risk for incident falls and fractures compared to low BMD or sarcopenia alone.

Material and Methods: MEDLINE, Embase, Web of Science, CINAHL and AgeLine were searched from their inception to 2025 for eligible records. We included prospective studies of populations aged ≥50 years where individuals with osteosarcopenia were compared to individuals with low BMD (T-scores <-1.0) or sarcopenia alone. Random effects meta-analyses calculated risk ratios (RR) with 95% confidence intervals (95%CI) for incident falls and fractures. We also calculated interaction on additive (relative excess risk due to interaction; RERI) and multiplicative (multiplicative interaction ratio; MR) scales. RERI values >0 (with 95%CIs excluding 0) indicate that the absolute risk of combined low BMD and sarcopenia is greater than expected from adding their individual risks, whereas MR values >1 (with 95%CIs excluding 1) indicate a positive departure from multiplicativity on the RR scale, rather than excess absolute risk.

Results: Eight records (n=17,015) were included. Osteosarcopenia was associated with similar fracture risk to low BMD (RR: 1.00; 95%CI: 0.77, 1.30; k=7, I^2=53.7%), but higher risk than sarcopenia (RR: 1.68; 95%CI: 1.11, 2.55; k=6; I^2=51.1%). Falls risk did not differ for osteosarcopenia compared to low BMD (RR: 1.15; 95%CI: 0.44, 2.97; k=3; I^2=72.9%) or sarcopenia (RR: 1.06; 95%CI: 0.70, 1.59; k=3; I^2=1.1%). Synergy analyses showed pooled RERI estimates of 0.02 (95%CI: −0.71, 0.75; k=6) for fractures and −0.16 (95%CI: −0.60, 0.28; k=3) for falls, and MR estimates of 0.93 (95%CI: 0.58, 1.47; k=6) and 0.83 (95%CI, 0.64, 1.09; k=3), respectively.

Conclusions: The risk of incident fracture in osteosarcopenia is not significantly different to low BMD alone, but is increased compared with sarcopenia alone. Falls risk does not appear to differ between conditions. Given the lack of evidence that having both low BMD and sarcopenia increases risk beyond low BMD alone, current data do not support using osteosarcopenia as a separate diagnostic category.

P475

INTRINSIC CAPACITY REFLECTS MUSCULOSKELETAL VULNERABILITY: ASSOCIATION WITH OSTEOSARCOPENIA BUT NOT SARCOPENIA OR OSTEOPOROSIS

D. Sezer[1], S. Özkök[1], T. Erdoğan[1], S. Şahin Tırnova[1], N. Önür[1], S. Güven[1], D. Çetin[1], G. Bahat[1], M. Karan[1]

[1]Istanbul University, Istanbul Medicine Faculty, Department of Internal Medicine, Divisions of Geriatrics, Istanbul Musculoskeletal Health Consortium, Istanbul, Türkiye

Objectives Intrinsic capacity (IC) reflects the physical and mental capacities underlying functional ability in older adults. Although IC has been linked to sarcopenia, its association with osteosarcopenia remains unclear. This study aimed to investigate the relationship between intrinsic capacity and osteosarcopenia.

Materials and Methods This retrospective cross-sectional study included patients aged 65 years and older who visited a tertiary geriatric outpatient clinic between November 2012 and December 2025 and underwent comprehensive geriatric assessment. Intrinsic capacity was assessed using the WHO Integrated Care for Older People (ICOPE) framework, covering cognitive, locomotor, vitality, psychological, and sensory domains. Sarcopenia and osteoporosis were defined according to established criteria, and osteosarcopenia was defined as the coexistence of both conditions. Participants were classified into mutually exclusive phenotypic groups of sarcopenia alone, osteoporosis alone, and osteosarcopenia. For each analysis, intrinsic capacity score was modeled as the independent variable, and sarcopenia, osteoporosis, and osteosarcopenia were analyzed separately as binary outcomes using multivariable-adjusted logistic regression models.

Results A total of 810 participants were included in the analysis. The mean age of the study population was 74.6 ± 6.6 years, and 69.8% were female. The prevalence of sarcopenia, osteoporosis, and osteosarcopenia was 11.1%, 17.2%, and 5.1%, respectively. Total IC scores differed significantly across phenotypic groups ($p < 0.001$), with the lowest scores observed in individuals with osteosarcopenia. In unadjusted analyses, higher IC scores were associated with lower odds of sarcopenia (OR = 0.83, 95% CI 0.73–0.95) and osteosarcopenia (OR = 0.69, 95% CI 0.58–0.82), but not osteoporosis. After full adjustment for age, sex, smoking status, and polypharmacy, total IC scores remained independently associated with osteosarcopenia (OR = 0.79, 95% CI 0.65–0.95), whereas no independent associations were observed for sarcopenia or osteoporosis alone.

Conclusions Lower IC score is independently associated with osteosarcopenia but not with sarcopenia or osteoporosis alone. These findings suggest that intrinsic capacity captures the combined burden of muscle and bone impairment and may serve as a functional marker to identify older adults at increased musculoskeletal vulnerability.

Table 2. Logistic regression results for the association between total intrinsic capacity score and musculoskeletal phenotypes

	Sarcopenia OR (95% CI)	p-value	Osteoporosis OR (95% CI)	p-value	Osteosarcopenia OR (95% CI)	p-value

NORDIC WALKING AS AN ACCESSIBLE METHOD OF PRIMARY PREVENTION OF SENILE ASTHENIA IN THE CHUVASH REPUBLIC

E. Antonova[1], E. Guryanova[2,3], A. Bilalova[4], J. Sharonova[4], D. Sideltsev[4], E. Fomina[4], N. Alekseeva[3], L. Bubnova[3], E. Shamitova[4]

[1]The State Autonomous Institution of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of Chuvashia., Cheboksary, Russia; [2]State Autonomous Institution of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic., Cheboksary, Russia; [3]Federal State Budgetary Educational Institution of Higher Education "I. N.Ulyanov Chuvash State University, Cheboksary, Russia; [4]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia

Objective. To analyze the effectiveness of systematic Nordic walking classes and assess their impact on the quality of life of the elderly.
Materials and methods. 76 patients (30 men, 46 women) were examined using the SF-36 questionnaire. The average age of the patients was 65.6 [53.9; 77;3]
Results. For 5 months (from January to May 2025), the regional office of medical volunteers for the elderly conducted master classes in Nordic walking on the territory of public spaces. Classes were held 2-3 times a week for 30-40 minutes. The exclusion criteria were: patients with acute cardiovascular diseases, severe forms of arterial hypertension, decompensated diabetes mellitus, acute inflammatory diseases, severe osteoporosis with a risk of fractures, as well as postoperative conditions. Before the training, joint exercises were performed, the correct Nordic walking technique was taught, and sticks were selected. The quality of life was assessed at the first master class and at the lesson 5 months later using the SF-36 questionnaire.
According to the PF scale of physical functioning, the baseline level was 50.3 [39.2; 61.4], and after 5 months of regular training – 61.4 [52.9; 69.9]. In the category of "Role-playing physical functioning" (RP), the baseline level was 47.8 [38.5; 57.1], and after 5 months it was 56.2 [42.5; 69.9]. The intensity of pain (Body pain — BP) decreased from 58.4 [55.1; 61.7] to 49.4 [46.8; 52.0]. Overall health (GH) improved from 59.3 [51.2; 67.4] to 67.2 [60.4; 74.0]. Viability (VT) increased from the initial 57.2 [44.8; 69.6] to 65.9 [57.6; 74.2]. The indicator of social functioning (SF) increased from 45.8 [36.2; 55.4] to 59.3 [53.1; 65.5]; role-emotional — from 54.2 [40.4; 68.0] to 67.3 [55.9; 78.7]; mental health (MH) - from 61.7 [52.2; 71.2] to 70.1 [64.5; 75.7].
Conclusions. Regular Nordic walking improved all indicators of quality of life according to the SF-36 questionnaire after 5 months of regular Nordic walking. The greatest changes were observed in the categories of physical functioning (FF) and social functioning (SF). Thus, regular aerobic training in the fresh air helps to improve the overall physical and psycho-emotional state.

EFFECTS OF PERIODIC REHABILITATION ON FUNCTIONAL INDEPENDENCE AND PREVENTION OF OSTEOPOROTIC FRACTURES IN STIFF-PERSON SYNDROME

D. Stoicanescu[1], M. Cevei[2], S. Deac[2], G. Gherle[2], R. Mihut[2], F. Andronie Cioara[2]

[1]University of Medicine and Pharmacy “Victor Babes”, TIMISOARA, Romania; [2]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania

Stiff-Person syndrome is a rare autoimmune disorder characterized by progressive muscle stiffness and painful muscle spasms. It has been linked to antibodies against GAD65, disrupting inhibitory neurotransmission in the central nervous system. We report a female patient, 54 years old, diagnosed with Stiff-Person syndrome 17 years ago. She also has autoimmune thyroiditis and other comorbidities: stage 1 hypertension with moderate cardiovascular risk, migraine, anxiety–depressive disorder. She was admitted in the Medical Rehabilitation Clinical Hospital Baile Felix, for back pain, bilateral knee and ankle pain, headache. Clinical examination revealed lumbar hyperlordosis, orthostatism with a wide base of support, difficult and unbalanced gait, sensitive on the toes and impossible on the heels, muscle contractures, significant muscle spasticity, painful shoulder mobility, positive Babinski sign on the right side, vivid deep tendon reflexes, more pronounced on the left side. The Johns Hopkins Fall Risk Assessment Tool established a high risk of falling, with a score of 15 points. The patient's functional independence and functional ambulatory category were assessed using the FIM (Functional Independence Measure) and FAC (Functional Ambulation Classification) scale, respectively. FIM score was 94 out of 126, 74.60%. FAC score assessing walking ability was 5, indicating the patient was fully independent. BMD determined by DXA showed lumbar spine T-score: -1.2, indicating osteopenia. Objectives of rehabilitation treatment: decreasing pain; maintaining joint mobility, trunk stability, coordination, prevention of falls / osteoporotic fractures, increase in bone and muscle mass. Complex medical rehabilitation focused on personalized therapy was performed every 3 months in our hospital. Physical therapy, hydrokinetotherapy (36°C oligomineral thermal water pool), underwater shower, virtual reality therapy, analgesic electrotherapy, occupational therapy and medication led to a favorable evolution with maintenance of functionality. Conclusion: Management of high fall risk, including inpatient periodic medical rehabilitation and monitoring bone mineral density, prevents osteoporotic fractures.

P478

ASSOCIATION BETWEEN LONG-TERM AIR POLLUTION EXPOSURE AND NON-TRAUMATIC OSTEONECROSIS OF THE FEMORAL HEAD

D. T. Nguyen[1,2], C.-C. Chen[3], Y.-Z. Lian[4], N. T. B. Nguyen[2,5], Y.-J. Kuo[6,7], Y.-P. Chen[7,8]

[1]The International Ph.D Program in Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [2]Department of Joint Surgery and Sport Medicine, Hue Central Hospital, Hue, Vietnam; [3]Department of General Medicine, Changhua Christian Hospital, Changhua, Taiwan; [4]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan; [5]Department of Surgery, Faculty of Medicine, Nam Can Tho University, Can Tho, Vietnam; [6]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Vietnam; [7]Department of Orthopedics, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [8]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan

Objectives
Although air pollution is linked to bone disorders, its association with non-traumatic osteonecrosis of the femoral head (ONFH) is unclear. We examined whether long-term ambient pollutant exposure increases ONFH risk.

Materials and Methods
A nationwide Taiwanese cohort of 585,334 adults was evaluated using 10-year cumulative exposure to SO2, CO, PM2.5, PM10, NOX, NO, NO2, THC, NMHC, and CH4. Pollutant levels were assigned by residential postal codes and time-weighted averages from monitoring stations. ONFH (ICD-9-CM 733.42) was identified from claims. Cox models adjusted for demographics, comorbidities, medications, urbanization, temperature, and season. Exposure–response relationships were assessed continuously and by tertiles.

Results
Over 10.8 years, 1,549 individuals developed ONFH. Higher long-term exposure to most pollutants correlated with increased risk. Adjusted hazard ratios (per SD) were: SO2 1.31, CO 1.78, PM2.5 1.76, PM10 1.44, NOX 1.56, NO 1.40, NO2 1.59, THC 1.64, NMHC 1.18, and CH4 2.15. Tertile analyses showed stepwise increases in ONFH incidence, and multi-pollutant models yielded similar findings. Cumulative incidence curves showed higher rates in the highest exposure groups.

Conclusions
Chronic exposure to multiple ambient pollutants is associated with increased ONFH risk. The dose–response trend and biological plausibility suggest air quality as a modifiable environmental contributor. Integrating exposure assessment into future mechanistic and population studies may support prevention and early detection.

Acknowledgments
Supported by Wan Fang Hospital (Grant No. 114-wf-eva-09).

SERUM LIPID ABNORMALITIES AND RISK OF OSTEONECROSIS OF THE FEMORAL HEAD: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. T. Nguyen[1,2], V. H. Tran[2], N. T. B. Nguyen[2,3], Y.-J. Kuo[4,5], Y.-P. Chen[4,5]

[1]The International Ph.D Program in Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [2]Department of Joint Surgery and Sport Medicine, Hue Central Hospital, Hue, Vietnam; [3]Department of Surgery, Faculty of Medicine, Nam Can Tho University, Can Tho, Vietnam; [4]Department of Orthopedics, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan; [5]Department of Orthopedics, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan

Objective:
To determine whether alterations in serum lipid profiles are associated with osteonecrosis of the femoral head (ONFH) by synthesizing evidence from observational studies.

Material and Methods:
A systematic search of PubMed, Embase, and Scopus was conducted up to July 2025 following PRISMA 2020 guidelines. Case–control and cohort studies reporting lipid parameters in ONFH and control groups were eligible. Mean differences (mmol/L) were pooled using random-effects models. Heterogeneity, subgroup analyses according to etiology, and leave-one-out sensitivity tests were performed. Small-study effects were assessed using Egger's regression.

Results:
Fourteen studies encompassing 24,331 participants were included. Patients with ONFH exhibited significantly higher triglyceride concentrations (MD 0.28; 95% CI 0.13 to 0.43; p=0.0002). Total cholesterol and LDL-cholesterol showed modest, non-significant increases, while HDL-cholesterol displayed a downward trend. Sensitivity analyses revealed that exclusion of specific outlier datasets reduced heterogeneity and yielded statistically significant differences for LDL-cholesterol and HDL-cholesterol without altering the direction of effects. The elevation in triglycerides was most evident in idiopathic and glucocorticoid-related ONFH. No evidence of publication bias was detected across outcomes (all p>0.05).

Conclusion:
Abnormalities in serum lipids, particularly elevated triglycerides, are consistently linked with ONFH, supporting the contribution of metabolic disturbances to disrupted femoral head perfusion. Early detection and management of dyslipidemia may provide an opportunity to reduce ONFH risk in populations exposed to corticosteroids or other predisposing factors.

P480

ASSOCIATION OF BMD AND FRAX SCORE WITH FRACTURE RISK IN ADULTS WITH TYPE 2 DIABETES IN AN ASIAN COHORT – THE HONG KONG OSTEOPOROSIS STUDY

D. T.-W. Lui[1], X. Zhang[1], A. W.-C. Kung[1], K. C.-B. Tan[1], C.-L. Cheung[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong SAR China

Objective: Type 2 diabetes is associated with higher bone mineral density (BMD) yet increased fracture risk. The recommendation of reducing femoral neck (FN) BMD T-score by 0.5 for better estimation of fracture risk in type 2 diabetes is primarily derived from Caucasian cohorts. Given different epidemiology of diabetes and osteoporosis among Asians, it is necessary to evaluate associations of BMD and FRAX score with fracture risk in type 2 diabetes among Asians.

Material and Methods: We analysed data from the prospective community-based Hong Kong Osteoporosis Study (comprising Chinese individuals recruited from 1995–2010 for comprehensive bone health assessments including DXA). Participants aged ≥40 years were included in this analysis. Their baseline diabetes status was ascertained by self-report, ICD-9 code 250, fasting glucose ≥7.0 mmol/L or use of anti-diabetic medications. Fractures were ascertained by detailed review of electronic medical records. Adjusted hazard ratio (aHR) with 95% confidence interval (CI) for fracture was computed with adjustment for age and sex.

Results: In total, 4175 women and 1708 men were included. 10.8% (n=629) had diabetes (all type 2 diabetes) and with FRAX. Mean age was 69.6±9.8 years, BMI 23.8±3.6 kg/m^2, FN BMD 0.63±0.14 g/cm^2, and FRAX score was 6.1±7.9% for hip and 12.9±11.6% for major osteoporotic fractures (MOF). Of the 629 people with diabetes, 107 experienced hip and 152 experienced MOF during mean follow-up of 12.8±7.2 years and 12.1±7.2 years. aHR for one unit decrease in FN BMD T-score in people with diabetes were 1.32 (95% CI 1.06–1.64) for hip and 1.33 (95% CI, 1.12–1.59) for MOF. FRAX score was also associated with fracture risk in people with diabetes. For a given FN BMD T-score and age or FRAX score, people with diabetes had a higher fracture risk than those without diabetes. For a similar hip fracture risk, people with diabetes had a higher T-score than people without diabetes. The difference in T-score was 0.99 (95% CI 0.71–1.26) for women and 0.57 (95% CI 0.26–0.89) for men.

Conclusion: FN BMD T-score and FRAX score were associated with risk of hip and MOF in Asian adults with type 2 diabetes. The magnitude of adjustment in FN BMD T-score to account for diabetes-related fracture risk in Asians may be more than the 0.5 unit suggested for Caucasians.

P481

DEVELOPMENT AND VALIDATION OF DIABETES HIP FRACTURE SCORE (D-HFS) IN PATIENTS WITH TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY OF HONG KONG

D. T.-W. Lui[1], Y. Zhang[1], C. H.-Y. Fong[1], M. Chandran[2], W.-S. Chow[1], K. C.-B. Tan[1], C.-H. Lee[1], Y.-C. Woo[1], K. S.-L. Lam[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong SAR China; [2]Duke NUS Medical School, Singapore, Singapore

Objective: Type 2 diabetes (T2D) is associated with increased risk of hip fracture and post-fracture morbidity. We developed and validated a Diabetes Hip Fracture Score (D-HFS) using population-based electronic health record (EHR) with well-characterised patients with T2D.

Material and Methods: We identified Chinese T2D patients aged ≥40 years who underwent comprehensive diabetes complication assessment during 2008 – 2012 (defined as the index date) in Hong Kong from population-based EHR. Hip fractures were identified by validated ICD-9 code 820. Patients were followed from index date till hip fractures, death, or end of 2023. The cohort was randomly divided 7:3 into development and validation cohorts. D-HFS was build using Fine and Gray model incorporating variables with univariate significance, considering death as competing risk, with model selection based on lowest AIC. Performance of D-HFS was evaluated in validation cohort, and compared with FRAX and other published diabetes-specific hip fracture prediction tools (derived from FDS-I and SIDIAP) using DeLong test.

Results: In total, 254,791 T2D patients were included (age 63.8±11.0 years, 49.1% men, BMI 25.7±3.8 kg/m^2). Upon median follow-up of 12.7 years (IQR: 11.1 – 14.3), 11,368 patients had hip fractures (incidence: 3.8 per 1000 person-years). D-HFS consisted of 11 variables: age, sex, BMI, smoking, history of major osteoporotic fractures, history of fall, diabetes duration, HbA1c, eGFR, statin and anti-diabetic medication use. D-HFS performed well in the validation cohort (5-year prediction at optimal threshold 1.51%: AUC 0.838 [95% CI 0.835–0.841], sensitivity 76.5%, specificity 76.4%, PPV 4.0%, NPV 99.6%; 10-year prediction at optimal threshold 3.63%: AUC was 0.822 [95% CI 0.820–0.824], sensitivity 75.2%, specificity 75.2%, PPV 9.0%, NPV 98.9%). Brier score was 0.012 for 5-year and 0.028 for 10-year prediction, suggesting good calibration. D-HFS performed better than FRAX (AUC 0.79), FDS-1 (0.77) and SIDIAP (0.78) hip fracture risk prediction tools (all p<0.001 vs D-HFS).

Conclusion: We developed and validated D-HFS from the largest database of Chinese T2D patients, applicable to electronic clinical management system to facilitate timely fracture risk stratification and preventive strategies to optimize bone health in T2D.

P482

COMPARATIVE EFFECTS BETWEEN RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM INHIBITORS AND CALCIUM-CHANNEL BLOCKERS ON THE RISK OF MAJOR OSTEOPOROTIC FRACTURES IN PATIENTS TYPE 2 DIABETES: A TERRITORY-WIDE COHORT STUDY OF HONG KONG

D. T.-W. Lui[1], X. Zou[1], X. Xiong[1], M. Chandran[2], C.-H. Lee[1], C. H.-Y. Fong[1], K.-S. Cheung[1], C. K.-H. Wong[1], W.-S. Chow[1], K. C.-B. Tan[1], Y.-C. Woo[1], K. S.-L. Lam[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong SAR China; [2]Duke NUS Medical School, Singapore, Singapore

Objective: We compared risks of major osteoporotic fractures (MOF) among users of renin-angiotensin-aldosterone system (RAAS) inhibitors (angiotensin converting enzyme inhibitors [ACEi] and angiotensin receptor blockers [ARB]) with users of calcium channel blockers (CCB), two most common anti-hypertensive classes, in people with type 2 diabetes (T2D).

Materials and Methods: We identified patients with T2D aged ≥40 years who underwent comprehensive diabetes complication evaluation during 2008–2012 (defined as the index date) from territory-wide electronic health records of Hong Kong. Individuals were classified as ACEi/ARB and CCB users based on their prescriptions at index date. Outcomes of interest were hip fracture (ICD-9 code 820) and MOF (ICD-9 805, 812–814, 820). They were followed from index date till outcomes, death or end of 2023, whichever earlier. Propensity-score (PS) weighting with inverse probability of treatment weighting was applied to balance baseline characteristics between ACEi/ARB and CCB users. Hazard ratios (HR) were computed using Cox proportional hazards models.

Results: 107,099 patients were included (51,863 RAASi users; 55,236 CCB users): mean age 64.9 years; 52.3% female. Upon median follow-up of 12.8 years, 4950 hip fractures and 5163 MOF occurred. Characteristics were balanced after PS weighting. RAASi use was associated with reduced risk of hip (HR 0.72 [95% CI 0.68–0.76], p<0.001) and MOF (HR 0.77 [0.73–0.82], p<0.001) compared to CCB use. Subgroup analyses were consistent across age, sex, comorbidity burden, BMI, HbA1c and diabetes duration, whereas protective effect was more prominent among those with preserved eGFR (p interaction<0.001). Sensitivity analyses by time-varying exposure, 1:1 PS matching and new-user design were consistent. There was no difference in risk of peptic ulcer disease (falsification endpoint) between both groups (p=0.77). Further stratification of RAASi use showed that both ACEi and ARB use was associated with lower hip fracture risk than CCB use (HR for ACEi 0.60 [0.54–0.66], HR for ARB 0.56 [0.41–0.76], p<0.001 vs CCB) with no difference between ACEi and ARB (p=0.66).

Conclusion: RAASi initiation was associated with lower fracture risk in people with T2D compared with CCB, supporting its role as the preferred anti-hypertensive in T2D.

P483

PREDIABETES IS ASSOCIATED WITH INCREASED RISK OF SARCOPENIA IN MEN AND POSTMENOPAUSAL WOMEN AGED ≥50 YEARS – A COMMUNITY-BASED COHORT STUDY OF HONG KONG

D. T.-W. Lui[1], C. C.-K. Lam[1], R. H.-W. Yuen[1], C. H.-Y. Fong[1], W.-S. Chow[1], K. C.-B. Tan[1], Y.-C. Woo[1], K. S.-L. Lam[1], C.-H. Lee[1]

[1]The University of Hong Kong, Hong Kong, Hong Kong SAR China

Objective: While ample evidence shows diabetes increases risk of sarcopenia, less is known about association between prediabetes and sarcopenia. We evaluated risk of sarcopenia across glycemic status in a community-based cohort.

Materials and Methods: Participants aged 50–74 years (postmenopausal for women) were invited as part of the prospective New Hong Kong Cardiovascular Risk Factor Prevalence Study (N-CRISPS) during 2019 – 2024. Each participant received DXA (Hologic Discovery A) for appendicular skeletal muscle mass (ASM), Jamar hand dynamometer for handgrip strength (HGS) and 5-time chair-stand test for physical performance. Sarcopenia is defined by low muscle mass (BMI-adjusted ASM) and strength (HGS) according to Asian Working Group for Sarcopenia 2025 criteria with age-specific thresholds for 50–64 and ≥65 years respectively. Participants were classified into normoglycemia (NG), prediabetes and diabetes according to HbA1c and 75-gram oral glucose tolerance test. Characteristics were compared across glycemic status. Multivariable regression analyses were performed to examine the independent associations between glycemic status and sarcopenia.

Results: In total, 588 participants were recruited (mean age 63±7 years; 46.6% female; BMI 24.0±3.2 kg/m^2): NG in 52.0%, prediabetes in 29.3%, and diabetes in 18.7%. Overall prevalence of sarcopenia was 13.6%. In both sexes, prevalence of sarcopenia increased with worsening glycemic status (men: 9.3% in NG, 16.8% in prediabetes, 18.8% in diabetes [p=0.04]; women: 9.0% in NG, 18.2% in prediabetes, 22.0% in diabetes [p=0.01]). Risk of sarcopenia started to increase from prediabetes (vs NG - men: age-adjusted OR [aOR] 2.23 [95% CI 1.02-4.88], p=0.045; women: aOR 2.64 [1.16–6.01], p=0.02), and further in diabetes (vs NG - men: aOR 2.69 [1.16–6.24], p=0.021; women: aOR 3.55 [1.36–9.27], p=0.010). This was driven by progressively lower BMI-adjusted ASM with worsening glycemic status (p<0.001 in both sexes). Although HGS did not differ across glycemic status, physical performance tended to be worse with worsening glycemic status (p=0.04 in men; p=0.14 in women).

Conclusion: Prediabetes is independently associated with increased risk of sarcopenia in both men and women, related to lower muscle mass and associated with poorer physical performance.

P484

CLINICAL EFFICACY OF NUCLEAR MAGNETIC RESONANCE THERAPY IN THE EARLY STAGES OF GONARTHROSIS: RESULTS OF A COMPARATIVE ANALYSIS

D. V. Yusupova[1], V. O. Fishchenko[1]

[1]National Pirogov Memorial Medical University, Vinnitsya, Ukraine

A prospective clinical and experimental study was conducted to evaluate the efficacy of nuclear magnetic resonance therapy (NMRT) in patients with early-stage gonarthrosis. The objective was to determine whether the addition of NMRT to standard therapy enhances clinical outcomes compared with standard therapy alone.

The study included 47 patients diagnosed with early-stage gonarthrosis. All participants received a standard treatment protocol consisting of intra-articular hyaluronic acid injections, physiotherapeutic procedures, and spa-based rehabilitation. The main group additionally underwent NMRT sessions, while the control group continued on standard therapy only. Clinical outcomes were assessed using the Visual Analogue Scale (VAS) for pain intensity and the Lequesne Index to evaluate functional status of the knee joint.

The results demonstrated a significant improvement in the group receiving NMRT. Pain severity measured by VAS decreased by an average of 3.2 points, compared with 1.7 points in the control group. Functional outcomes, as assessed by the Lequesne Index, showed a 38% improvement in the NMRT group, compared with 21% in the control group. Importantly, NMRT was well tolerated by patients, with no systemic adverse effects reported, indicating its safety for use in individuals with chronic comorbidities.

The findings confirm the therapeutic potential of NMRT in managing early-stage gonarthrosis. Its beneficial effects are likely associated with stimulation of reparative processes in cartilage, reduction of inflammatory responses, and improvement of microcirculation in the affected joint. Integration of NMRT into comprehensive treatment protocols appears to provide superior outcomes compared with standard therapy alone. These data support the consideration of NMRT as a promising modality in multimodal management strategies for knee osteoarthritis. Further large-scale investigations are warranted to establish optimal treatment parameters and to confirm its long-term efficacy.

P485

THE ROLE OF PREVENTIVE PLASMAPHERESIS DURING RITUXIMAB TREATMENT IN RHEUMATIC DISEASES

N. Y. Nikishina[1], E. A. Pletnev[1], E. A. Aseeva[1], E. V. Nikolaeva[1], S. K. Soloviev[1], E. G. Zotkin[1]

[1]VA Nasonova Scientific Research Institute of Rheumatology, Moscow, Russia

Objective: The aim of this study was to evaluate the outcomes of plasmapheresis initiated before or during rituximab treatment as a strategy for flare prevention.

Materials and methods: This study was conducted at our tertiary referral center between 2023 and 2024. We included 34 patients (32 women and 2 men), mean age of 47 [17; 71] years, with a diagnosis of Sjogren's disease in 20 patients, Sjogren's disease in combination with rheumatoid arthritis or systemic lupus erythematosus in 5 and 9 patients, respectively. All patients received prednisone at a dose of 11.7±4.4 mg . To reduce hypergammaglobulinemia and minimize the risk of vasculitis flare after rituximab infusion, patients underwent 1 to 3 sessions of membrane plasmapheresis. The volume of treated plasma ranged from 600 to 2000 mL per session. Following plasmapheresis, rituximab infusion was administered.

Results: The treatment resulted in significant improvements in laboratory parameters: immunoglobulin G (IgG) level decreased from 27.94±16.62 g/L to 25.62±23.82 g/L (p=0.001); erythrocyte sedimentation rate decreased from 61.96±37.90 to 28.41±23.82 mm/h (p=0.001); total protein level decreased from 86.26±10.62 to 75.62±9.68 g/L. A positive statistical correlation was found between the total protein level and IgG (r=0.403). Subsequently, all patients received rituximab infusion with no adverse events reported. A complete clinical response was achieved in all patients.

Conclusions: Our results showed that plasmapheresis was an effective and well tolerated intervention for hypergammaglobulinemia control to prevent rituximab-associated flares .

P486

EFFECTIVE TREATMENT OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS VIA SELECTIVE CFDNA/NETS APHERESIS

E. A. Aseeva[1], E. A. Pletnev[1], N. S. Pokrovsky[2], S. K. Soloviev[1], E. G. Zotkin[1], N. Y. Nikishina[1], E. T. Abdulin[3]

[1]VA Nasonova Scientific Research Institute of Rheumatology, Moscow, Russia; [2]National Medical Research Center of Cardiology Named after Academician E.I. Chazov, Moscow, Russia; [3]Lomonosov Moscow State University, Moscow, Russia

Objective. Evaluation of efficacy and safety of therapeutic apheresis using new adsorption column for selective cfDNA/NETs apheresis in patients with difficult-to-treat RA.

Materials and methods. Three patients with active, difficult-to-treat RA underwent three sessions of selective cfDNA/NETs apheresis with a one-day interval between procedures. All patients were treated with 6-methylprednisolone (10 mg/day) and previously shown insufficient response to disease-modifying antirheumatic drugs. Therapeutic apheresis procedures were conducted using new medical device for selective cfDNA/NETs apheresis to decrease the disease activity before initiating rituximab as main treatment. The volume of treated plasma per procedure was approximately 2 volumes of circulating plasma. Disease activity (DAS28-CRP, DAS28-ESR) and laboratory parameters were assessed before and after treatment.

Results. All three sessions of selective cfDNA/NETs apheresis were well tolerated by all patients, with no significant adverse effects reported during or after the procedure. All patients showed improvement in disease activity as measured by both the DAS28-ESR and DAS28-CRP scores after treatment. The average reduction in DAS28-ESR was 2.5, and the average reduction in DAS28-CRP was 1.77. Selective cfDNA/NETs apheresis significantly reduced CRP and ESR levels in two out of three patients, indicating a positive treatment response. The changes in RF and ACPA levels were more variable compared to CRP and ESR, with two patients showing either minimal or no reduction in these autoantibodies, while one patient showed a significant decrease.

Conclusion. The first results with selective cfDNA/NETs apheresis

column demonstrated significant clinical and laboratory results in the treatment of difficult-to-treat RA.

P487

SELECTIVE CFDNA/NETS APHERESIS AS A THERAPEUTIC APPROACH IN SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS

E. A. Aseeva[1], E. A. Pletnev[1], N. Y. Nikishina[1], S. K. Soloviev[1], E. T. Abdulin[2], N. S. Pokrovsky[3], E. G. Zotkin[1]

[1]VA Nasonova Scientific Research Institute of Rheumatology, Moscow, Russia; [2]Lomonosov Moscow State University, Moscow, Russia; [3]National Medical Research Center of Cardiology Named after Academician E.I. Chazov, Moscow, Russia

Objective: To evaluate the efficacy and safety of a novel therapeutic apheresis approach using an adsorption column for selective removal of circulating free DNA (cfDNA) and NETs in patients with severe SLE.
Materials and Methods: Three patients with severe SLE, high disease activity, skin involvement (vasculitis), and elevated immunological markers underwent three sessions of selective cfDNA/NETs apheresis at one-day intervals. Disease-modifying antirheumatic drugs, 6-methylprednisolone and previous rituximab therapy had shown limited effectiveness. Selective apheresis procedures were conducted using a novel medical device, followed by pulse therapy with methylprednisolone. Each procedure processed approximately two volumes of circulating plasma. Complete blood count, immunological markers, and disease activity (SLEDAI-2K score) were assessed before treatment and after the third apheresis session.
Results: All three patients tolerated the apheresis sessions well, with no major adverse effects. In the first clinical case (68-year-old male), SLEDAI-2K decreased from 12 to 4, with reductions in anti-dsDNA and anti-Sm levels. In the second case (56-year-old female), SLEDAI-2K improved from 32 to 12, with decreases in anti-dsDNA and anti-Sm. In the third case (51-year-old female), SLEDAI-2K declined from 17 to 8, with reductions in anti-dsDNA and anti-C1q. Vasculitis resolved in two patients, while C3 and C4 remained low in all. ESR and leukocyte counts improved across cases.
Conclusion: The selective cfDNA/NETs apheresis column demonstrated significant clinical and laboratory improvements in severe SLE treatment.

P488

CLINICAL RELEVANCE OF REPEATED KIDNEY BIOPSIES IN LUPUS NEPHRITIS

N. Y. Nikishina[1], E. A. Aseeva[1], E. A. Pletnev[1], S. K. Soloviev[1], E. G. Zotkin[1]

[1]VA Nasonova Scientific Research Institute of Rheumatology, Moscow, Russia

Objective: To demonstrate the clinical value of kidney biopsy for patients with lupus nephritis in order to select personalized therapy.
Methods: Patient K., 30 years old, has been followed since 2012 with a confirmed SLE diagnosis (SLICC ACR 2012). Disease onset included articular and skin syndromes, leukopenia. Immunological tests showed anti-DNA, ANF, anti-Sm. Treatment included hydroxychloroquine 400□200 mg/day and glucocorticosteroids 16□4 mg/day, stopped in 2019 after remission. In 12.2020, arthritis of hands and feet and lupus nephritis developed. In 02.2021, hospitalization revealed elevated anti-dsDNA, ANF, RNP-70, aCL, aBeta-2-GP-1, decreased C3, C4, leukopenia, leukocyturia, erythrocyturia, proteinuria 0.8 g/day. Kidney biopsy showed diffuse proliferative GN with 11% segmental fibrocellular crescents (activity index 5, chronicity 1). Given young age, high disease activity (SLEDAI 2K=20), rapid progression, and life-threatening renal involvement (class IV LN), pulse methylprednisolone (6 doses, total 4 g), Rituximab, mycophenolate mofetil 2000 mg/day, increased corticosteroids (25 mg/day), hydroxychloroquine 400 mg/day, and anticoagulants were initiated. Rituximab was infused every 6 months (total 4000 mg), corticosteroids tapered to 5 mg/day, and mycophenolate and hydroxychloroquine continued. This led to remission (SLEDAI 2K=0). After 24 months, repeat kidney biopsy showed class II mesangioproliferative GN (activity 0, chronicity 0). Pharmacological therapy was discontinued, and mycophenolate and corticosteroids were reduced.
Results: since there are no markers that reliably reflect the histopathology of the kidneys in SLE, a repeat kidney biopsy makes it possible to assess the activity of LN, the initial phase of immunosuppressive therapy, and to make decisions about its further correction.
Conclusions: Kidney biopsy remains the gold standard for establishing the diagnosis of LN and guiding clinical management. It allows for differential diagnosis in clinically complex cases, selecting adequate therapy based on the morphological form of kidney damage and avoiding the unreasonable prescription of glucocorticosteroids and cytostatics.

P489

UNIVERSAL ALOPECIA IN PATIENTS WITH ANKYLOSING SPONDYLITIS DURING GENETIC ENGINEERING THERAPY

E. Agafonova[1], A. Dimitreva[1], K. Sakharova[1], M. Urumova[1], S. Krasnenko[1], S. Erdes[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Case Study 1
Patient A., 22, suffers from AS. The disease onset was in 2010 with peripheral arthritis. He received therapy with disease-modifying antirheumatic drugs (DMARDs) – sulfasalazine (SS), methotrexate (MTX), and, due to coxitis progression, etanercept (2011–2014) – with insufficient effectiveness. In December 2014, he was prescribed adalimumab (ADA) 40 mg in combination with SS 1.5 g/day. In 2016, AU developed while on ADA therapy. In 2019, due to secondary ineffectiveness, the drug was replaced with tofacitinib 10 mg/day in combination with MTX 20 mg/week. During this therapy, the patient experienced hair regrowth. In 2020, due to persistently high clinical disease activity, the patient was prescribed an interleukin 17 (IL-17) inhibitor. Four months later, the patient experienced a relapse of UVA.
Case Study 2
Patient N., 33, diagnosed with AS. The disease onset was in 2006 with polyarthritis. He received therapy with MTX 10 mg/week and various nonsteroidal bDMARDs. In December 2011, high disease activity persisted, leading to initiation of treatment with infliximab (INF) 5 mg/kg in combination with MTX 12.5 mg/week, with a positive effect. In December 2012, patches of alopecia appeared on the body. INF was discontinued and prednisolone 10 mg/day was prescribed, after which hair growth resumed. However, given the exacerbation of joint syndrome and the juvenile onset of the disease, treatment with tocilizumab was initiated, and in 2019, prednisolone was resumed at 10 mg/day. During this therapy, relief of joint syndrome and gradual regrowth of hair were

observed.

Case Study 3

Patient B., 38, was diagnosed with AS in 2008. Due to the ineffectiveness of standard therapy, ADA therapy was initiated in February 2018, but was discontinued due to the development of allergic vasculitis. In November 2018, certolizumab pegol (CZP) therapy was initiated, with good results in relieving arthritis and reducing back pain. In March 2019, increased hair loss began. The drug was discontinued, but hair loss continued, and by July 2019, the development of AU was diagnosed. Due to exacerbation of the joint syndrome, CZP therapy was resumed.

Conclusion. The described cases of the development of AU during treatment with bDMARDs raise the question of further study of the pathogenesis of alopecia, the role of proinflammatory cytokines in its development, especially TNFα and IL17, as well as their influence on the occurrence of the disease.

P490

THE FREQUENCY OF COXITIS DETECTED BY X-RAY IN PATIENTS WITH AXIAL FORMS OF SPONDYLOARTHRITIS

E. Agafonova[1], T. Dubinina[1], E. Ilyinykh[1], A. Demina[1], S. Erdes[1], E. Gubar[1], T. Korotaeva[1], L. Vorobyova[1], I. Andrianova[1], P. Tremaskina[1], J. Korsakova[1], E. Loginova[1], K. Sakharova[1], A. Sablina[1], A. Smirnov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Introduction. According to epidemiological research conducted in Russia, damage to the hip joints (HJ) was observed in 46% of patients with ankylosing spondylitis (AS), while data on the incidence of coxitis in patients with psoriatic arthritis are lacking.

Objective. To determine the frequency of hip joint (HJ) damage in patients with axial spondyloarthritis (axSpA)/AS and psoriatic arthritis (PsA) with spinal involvement.

Materials and methods. A total of 222 patients (mean age 35.7 ± 12.7 years) were examined. The first group comprised 108 patients who met the ASAS (Assessment of Spondyloarthritis International Society) criteria for axSpA in 2009 or the AS criteria from 1984 [16]; the second group included 114 patients with axPsA who met the CASPAR criteria. Signs of axial involvement in PsA were determined using instrumental imaging techniques. The mean age of disease onset was 26.3 ± 20.3 years, and HLA-B27 was detected in 54% of patients. The diagnosis of coxitis was established based on pelvic X-ray examination and determination of the BASRI hip index for each joint.

Results: Among the 222 patients included in the study, 52 had X-ray signs of coxitis, including 22 patients with AS and 30 patients with axPsA. Patients were divided into two groups based on their diagnosis (Table 1).

Table 1

Parameters	axSpA (n=108)	axPsA n=114	p
Gender (m/f), n	62/46	58/56	>0,05
BMI (kg/m²),	24,7 [21,6; 28,1]	27,15[24,6;32,07]	<0,05
BASMI, Me [25th; 75th percentile]	2 [1;3]	3[2;4]	<0,05
Age, years	36,0 [26,5; 42]	45,5 [38;55]	<0,05
HLA-B27 presence, n (%)	91 (84,2%)	30 (24,5%)	<0,05
Uveitis, n (%)	18 (16,6%)	1 (1,22%)	<0,05
Peripheral joint arthritis, n (%)	76 (70,3%)	110 (90,1%)	<0,05
BASDAI, Me [25th; 75th percentile]	4,35 [2,8; 5,6]	5,8 [4,4; 7,0]	<0,05
ASDAS (CRP), Me [25th; 75th percentile]	2,19 [1,40; 2,74]	3,27[2,70; 3,24]	<0,05
ESR, mm/hour, Me [25th; 75th percentile]	11 [5; 30]	17 [7; 35,5]	<0,05
CRP, mg/ml, Me [25th; 75th percentile]	11,28 [1,1; 9,1]	16,7 [3,0; 20,1]	<0,05
BASFI, Me [25th; 75th percentile]	2,65 [0,85; 4,75]	3,9 [2,0; 6,0]	<0,05
X-ray coxitis, n%	22 (20,37%)	30 (26,3%)	>0,05

Conclusion: X-ray coxitis was detected in 20% of patients with axSpA and 26% in patients with axPsA. In previous global studies, the incidence of X-ray coxitis among patients with psoriatic arthritis and spondylitis did not exceed 10%. According to our study, patients with axPsA had higher clinical and laboratory activity of the disease compared to patients with axSpA, and they also exhibited pronounced functional impairments.

P491

CAPABILITIES OF FULL-BODY MRI IN RHEUMATOLOGY. CLINICAL CASE DESCRIPTION

E. Agafonova[1], T. Dubinina[1], S. Erdes[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Today, the assessment of the muscular and skeletal systems, blood vessels, heart, and even the intestines has become possible through a single examination — magnetic resonance imaging (MRI) of the entire body, which has also found application in rheumatology. This paper presents a clinical observation using whole-body MRI. Patient R., aged 28, was admitted to the clinic of the Nasonova Research Institute of Rheumatology with a referral diagnosis of spondyloarthritis, HLA B 27 negative with extra-axial manifestations (arthritis, coxitis). From the medical history, it is known that lower back pain first appeared during the third trimester of pregnancy in 2015 and resolved on its own after childbirth. Three months after delivery, pain in the spine resumed, primarily in the sacrum and lower back, with a constant nature that did not change

throughout the day and did not subside at rest or with physical activity. Over the course of four months, pain in the spine increased with radiation along the back of the thigh, and pain in the groin appeared. According to the examination conducted in July 2016 at the place of residence: C-reactive protein (CRP) negative, rheumatoid factor (RF) positive, antibodies to cyclic citrullinated peptide (ACCP) negative. There were no signs of sacroiliitis on the pelvic X-ray, leading to a diagnosis of probable rheumatoid arthritis. Therapy with nonsteroidal anti-inflammatory drugs (NSAIDs) and methotrexate (10 mg/week, later increased to 15 mg/week) was administered for three months without effect, with a worsening of the condition observed. Additional examinations revealed bilateral chronic sacroiliitis on MRI of the sacroiliac joints. Computed tomography of the lumbar spine showed degenerative and dystrophic changes, as well as a posterior hernia at L5-S1. Blood tests from September 2016 showed RF negative, CRP negative, ESR 12 mm/hour, leukocytes 12.6 × 10^9/L. Upon admission, the patient complained of mixed-type pain in the lumbar spine, hip, and knee joints, gait disturbances, and muscle weakness in the lower extremities. Examination revealed a "duck-like" gait with cane support. The patient could not remain in a static position for long periods. Spine movements were not limited, while hip joint movements were painful and restricted. Other joints had full, painless movement. Laboratory findings: hemoglobin 143 g/L, erythrocytes 4.43 × 10^{12}/L, leukocytes 8.6 × 10^9/L, platelets 406 × 10^9/L, ESR 8 mm/hr (Punch), CRP 0.7 mg/L, RF < 9.5 IU/ml, Anti-MCV 10.6 U/ml, parathyroid hormone 43.6 pg/ml, alkaline phosphatase 392 U/l, calcium 2.69 mmol/l, ionized calcium 1.26 mmol/l, phosphorus 0.63 mmol/l. Pelvic X-ray showed no signs of sacroiliitis but raised suspicion of femoral neck integrity disruption on the right side. To clarify the diagnosis, a whole-body MRI was performed, revealing bilateral fractures of the lateral sacral masses, bilateral fractures of the femoral heads, and areas of ischemic necrosis in the tibias bilaterally. Densitometry results showed a decrease in the Z-score to -3.0 in the lumbar spine and -3.1 in the left femoral neck. Daily urine analysis revealed calcium 2.44 mmol/l and phosphorus 10 mmol/l. Scintigraphy detected metabolic changes in the bone system. Based on these findings, the patient was diagnosed with hypophosphatemic osteomalacia and secondary systemic osteoporosis (Z-score -3.0 in the lumbar spine, -3.1 in the left femoral neck, -2.1 in the proximal left femur), with a progressive course. The patient underwent skeletal scintigraphy and a stromal tumor was detected in the upper third of the thigh.

P492

THE ROLE OF THE SINGLE NUCLEOTIDE POLYMORPHISM ARG25PRO OF TGFB1 GENE ON CLINICAL AND LAPORATORY PARAMETRES AND COMORBIDITY FORMATION IN PATIENTS WITH ANKYLOSING APONDYLITIS

I. Yatskov[1], A. Gaffarova[1], V. Beloglazov[1], E. Ageeva[1], D. Duryagina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to evaluate the effect of the SNP Arg25Pro of the TGFB1 gene on clinical and laboratory parameters and the formation of comorbidity associated with CVR in AS.

Materials and methods: The study included 176 patients diagnosed with AS. Genotyping was carried out according to the polymorphism of the Arg25Pro of the TGFB1 gene by the polymerase chain reaction method (PCR). The statistical analysis was carried out using the Kruskal-Wallis criterion.

Results: Patients with AS with the AP had a statistically significantly higher BMI (AA 24.9 [24.5; 28.1] kg/m2 vs. PP 25.4 [21.6; 30.8] kg/m2 vs. AP 28.3 [25.7; 32.7] kg/m2, p=0.012). In the presence of the A allele, higher glucose levels were detected at a statistically significant level (AA 5.4 [5.1; 6.0] mmol/l vs. PP 4.8 [4.4; 5.4] mmol/l vs. AP 5.2 [4.6; 5.8] mmol/l, p=0.027). Identification of the P allele resulted in higher creatinine values (AA 65.7 [57.0; 90.6] mmol/l vs. PP 79.1 [67.0; 90.0] mmol/l vs. AP 83.0 [77.0; 95.0] mmol/L, p=0.02), urea (AA 4.4 [4.0; 4.9] mmol/l vs. PP 5.0 [4.3; 5.8] mmol/l vs. AP 5.3 [4.4; 6.5] mmol/l, p=0.031) and uric acid (AA 272.0 [257.0; 346.5 mmol/l vs. PP 304.0 [218.8; 433.8] mmol/l vs. AP 344.5 [221.5; 442.5] mmol/l, p<0.05), especially in the state of heterozygotes with the AP genotype. Detection of the AP genotype was associated with high serum iron values (AA 12.2 [8.8; 14.8] mmol/L, PP 14.3 [11.1; 21.0] mmol/L, AP 17.0 [11.9; 21.8] mmol/L, p=0.03).

Extraskeletal manifestations were more frequently develop in patients with AP genotype at a statistically significant level (AA 4 (20.0%) vs. PP 18 (18.4%) vs. AP 18 (31.0), p=0.036).

Conclusion: The results of the study demonstrated for the first time the role of Arg25Pro SNP of the TGFB1 gene in the development of extraaxial and extraskeletal manifestations of AS, at the same time the impact in formation of comorbidities.

P493

PREDICTIVE VALUE OF TIMED UP AND GO AND USUAL GAIT SPEED FOR INCIDENT FRAILTY IN COMMUNITY-DWELLING OLDER ADULTS: A RETROSPECTIVE COHORT STUDY

E. Asci Civelek[1], O. Can Ceylan[1], Z. Sahin Tirnova[1], E. Pinar[1], T. Erdogan[1], S. Ozkok[1], G. Bahat[1], M. Karan[1]

[1]Istanbul University Istanbul Medical Faculty Department of Internal Medicine Division of Geriatrics, Istanbul, Türkiye

Objective: Frailty is a geriatric syndrome associated with adverse health outcomes. Simple physical performance tests such as the Timed Up and Go (TUG) and usual gait speed (UGS) may help identify older adults at risk of developing frailty; however, their predictive value for frailty development and optimal cut-off points have not yet been clearly defined. This study aimed to evaluate the associations between TUG, UGS, and frailty development in older adults.
Methods: This retrospective cohort study included 211 community-dwelling adults aged ≥65 years who were non-frail at baseline and underwent at least two comprehensive geriatric assessments in a university geriatrics outpatient clinic. Frailty was assessed using the FRAIL scale. Baseline clinical, functional, and physical performance measures were evaluated. Incident frailty during follow-up was the primary outcome. Receiver operating characteristic analyses(ROC) were performed to assess predictive performance and identify optimal cut-off values. Multivariable logistic regression models were used to examine factors associated with frailty development. Due to the high correlation between TUG and UGS, these measures were evaluated in separate models.
Results: The mean age of was 74 years, and 71.1% were female. Over a mean follow-up period of 34 months, frailty developed in 32 participants

(15.2%). Frailty incidence was significantly higher among individuals who were prefrail at baseline compared with those who were robust (33.7% vs. 1.6%).(table 1). ROC analysis demonstrated a moderate discriminative ability for TUG test (AUC = 0.648) and a good discriminative ability for UGS (AUC = 0.736). The optimal cut-off value was ≥9.3 seconds for TUG and ≤0.97 m/s for UGS. In minimally adjusted models, both prolonged TUG (OR 4.50, 1.17–11.85; p = 0.002) and reduced UGS (OR 15.46, 4.18–57.10; p < 0.001) were significantly associated with incident frailty. In fully adjusted models (adjusted for age, sex, malnutrition, baseline frailty status, chronic pain, impaired instrumental activities of daily living, and follow-up time), both prolonged TUG (OR 4.178) and reduced UGS (OR 9.11) remained independently associated with frailty development(table 2).

Conclusion :In this study, both prolonged TUG and reduced UGS were independently associated with incident frailty in community-dwelling older adults. Although UGS demonstrated a higher discriminative ability in ROC analysis, TUG showed a robust association with frailty development after comprehensive adjustment for clinical and functional covariates. These findings suggest that simple physical performance tests can be useful tools for identifying older adults at increased risk of frailty.

Table 1: Baseline Characteristics of Participants According to Incident Frailty Status

Variable	Participants With Incident Frailty (n=32, 15.2%)	Participants Without Incident Frailty (n=179, 84.8%)	p-value

Table 2:

	Prolonged TUG (≥9.3 s)		Reduced GYH (≤0.97 m/s)		
	OR	P value	OR	P Value	
Model 1	4.5(1.17-11.85)	0.002	Model 1	15.46(4.18-57.10)	0.000
Model 2	4.166(1.27-13.6)	0.018	Model 2	9.11(2.25-36.88)	0.002

Model 1 is adjusted for age and gender model 2 is adjusted for age, gender, malnutrition, baseline frailty state, chronic pain, impaired IADL, and follow up time.

P494

ABILITY OF ANTHROPOMETRIC MEASURES TO DISTINGUISH SARCOPENIC OBESITY FROM OBESITY WITHOUT SARCOPENIA

E. Asci Civelek[1], O. Can Ceylan[1], E. Pinar[1], S. Ozkok[1], M. Karan[1], G. Bahat[1]

[1]Istanbul University Istanbul Medical Faculty Department of Internal Medicine Division of Geriatrics, Istanbul, Türkiye

Objectives: This study aimed to evaluate the discriminative performance of selected anthropometric measures of adiposity in distinguishing between obesity subgroups to better capture SO cases in routine practice.
Methods: Older adults aged ≥60 years who attended the geriatrics outpatient clinic of a university hospital were included in the study. Participants were categorized into four body composition phenotypes: non-sarcopenic non-obese, obesity alone, sarcopenia alone, and SO. Anthropometric indices including body mass index (BMI), weight-adjusted waist index (WWI), waist-to-hip ratio (WHR), waist-to-height ratio (WHtR), abdominal volume index (AVI), A Body Shape Index (ABSI) and Body Adiposity Index (BAI) were calculated. SO was defined in line with the definition proposed by ESPEN/EASO consensus (i.e., altered muscle function + altered body composition). Receiver operating characteristic (ROC) curve analyses were conducted to evaluate the diagnostic accuracy of each index to discriminate *SO* from *obesity alone*. Logistic regression was performed to identify the association between anthropometric measures and *SO* vs *obesity alone*. Continuous indices were standardized using z-scores to allow comparability across models.
Results: A total of 1767 older adults, 68.5% female with a mean age 74 years were included in the analysis. Specifically, WWI, WHR, ABSI, and BAI values differed significantly between the obesity-alone and SO groups, whereas WHtR and AVI did not show significant differences(**Table 1**). Among the evaluated indices, WWI demonstrated the highest discriminative performance (AUC = 0.650), followed by ABSI (AUC = 0.642), WHR (AUC = 0.621) and BAI (AUC=0.591). Compared to reference group (*obesity alone*), only WWI, ABSI, and WHR values were independently associated with SO (OR = 1.77, 1.32, and 1.30; respectively) (**Table 2**).
Conclusion: In older adults, indices reflecting body shape and fat distribution outperformed adiposity-based measures in distinguishing sarcopenic obesity from obesity alone. Among these, WWI showed the strongest and most consistent association with sarcopenic obesity, supporting its potential utility as a practical screening tool in routine clinical practice.

Table 1: Comparison of clinical and body composition characteristics across sarcopenic obesity phenotypes

LOW SKELETAL MUSCLE–TO–FAT MASS RATIO IDENTIFIES SARCOPENIC OBESITY BUT DOES NOT PREDICT MORTALITY IN OLDER ADULTS

E. Asci Civelek[1], O. Can Ceylan[1], E. Pinar[1], S. Ozkok[1], T. Erdogan[1], M. Karan[1], G. Bahat[1]

[1]Istanbul University Istanbul Medical Faculty Department of Internal Medicine Division of Geriatrics, Istanbul, Türkiye

Objective: This study aimed to investigate the associations of the skeletal muscle–to–fat mass ratio (SMM/FM) with sarcopenic obesity and all-cause mortality in community-dwelling older adults.
Methods: This retrospective cohort study included 1,247 community-dwelling adults aged ≥60 years who underwent comprehensive geriatric assessment. SO was defined in accordance with the ESPEN/EASO consensus criteria (i.e., impaired muscle function combined with altered body composition). Sex-specific quintiles of the SMM/FM ratio (SS-Q1) were generated, and individuals in the lowest quintile were classified as having low SMM/FM. Logistic regression analyses were performed to identify factors associated with sarcopenic obesity, while Cox proportional hazards models were used to examine the association between SMM/FM and all-cause mortality.
Results: The mean age of the participants was 74 years, and 70% were women (n = 873). A total of 141 participants (11.3%) have SO and these were predominantly male, significantly older, frail, dependent in both basic and instrumental activities of daily living, and belonged to the lowest SMM/FM ratio (SS-Q1). In logistic regression analyses, belonging to SS-Q1 was independently associated with SO after adjustment for age and sex (Model 1; OR=7.09, 95% CI 4.76-10.56) and remained independently associated after further adjustment for frailty and functional dependency (Model 2; OR = 7.69, 95% CI 5.07–11.66). In Cox proportional hazards analysis, older age (HR = 1.11 per year, 95% CI 1.09–1.12) and male sex (HR = 1.95, 95% CI 1.55–2.45) were independently associated with all-cause mortality, whereas neither low SMM/FM (SS-Q1) nor sarcopenic obesity remained independently associated after adjustment for age and sex.
Conclusion: Low SMM/FM, particularly when defined using sex-specific quintiles, is a strong and independent determinant of sarcopenic obesity in community-dwelling older adults. However, neither low SMM/FM nor sarcopenic obesity independently predicted all-cause mortality after adjustment for age and sex, highlighting the dominant role of demographic factors in mortality risk.

P496

THE EFFECTIVENESS OF THE USE OF HARDWARE MECHANOTHERAPY IN THE PREVENTION OF KNEE JOINT CONTRACTURES IN PATIENTS AFTER INJURIES

E. Atabekov[1], E. Antonova[2], A. Bilalova[3], D. Sideltsev[3], E. Fomina[3], E. Guryanova[4,5], L. Bubnova[5], J. Sharonova[3], N. Alekseeva[5]

[1]Bishkek State Hospital of Kyrgyz-Turkish Friendship named after Recep Tayyip Erdogan, Bishkek, Kyrgyzstan; [2]The State Autonomous Institution of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of Chuvashia., Cheboksary, Russia; [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia; [4]State Autonomous Institution of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic., Cheboksary, Russia; [5]Federal State Budgetary Educational Institution of Higher Education "I. N.Ulyanov Chuvash State University, Cheboksary, Russia

The purpose of the study. To analyze the effectiveness of the use of hardware mechanotherapy in the prevention of knee joint contractures in patients after injuries.
Materials and methods. The retrospective study included 80 patients who were admitted for rehabilitation after consolidated fractures of the lower extremities at the State Clinical Hospital No.1. The main group consisted of 40 patients who received a comprehensive program of medical rehabilitation in the round–the-clock hospital, including

therapeutic gymnastics in the physical therapy room, massage of the lower extremity and lower back, amplipulstherapy, and electrical stimulation of the quadriceps femoris. All patients in the main group also underwent 20 minutes of hardware mechanotherapy of the lower extremities robotic devices daily during the rehabilitation course. The comparison group also included 40 patients who underwent a similar comprehensive medical rehabilitation program, but without hardware mechanotherapy.

Results. Initially, the patients of the two groups were comparable in age, height, body weight and BMI, as well as the frequency of contractures and joint stiffness.

After applying a comprehensive technique, we see an improvement in the results of angulometry in the main group. The use of hardware mechanotherapy had a 1.8-fold more effective effect on the angulometry of the main group of patients. All patients tolerated the procedure of hardware mechanotherapy well. Already from the 2nd day of the procedures, patients noted a decrease in pain, which had a positive effect on their level of activity and physical activity. Before treatment, patients could walk for an average of no more than 15-20 minutes a day, then after treatment they were able to walk for about 1 hour without stopping to rest.

Conclusions. The early use of hardware mechanotherapy in patients after lower limb injuries has increased the effectiveness of the rehabilitation complex in the main group of patients compared to the comparison group. This has led to a reduction in the recovery time after the injury, an increase in the functional range of motion, an increase in motor activity, and an improvement in the quality of life for patients.

The positive results provide a basis for the wider use of the proposed rehabilitation complex in practice for the prevention of knee joint contractures in patients after injuries. The use of robotic devices promotes fluid drainage and reduces swelling not only in the injured joint but also in the surrounding areas.

P497

HOW DOES LIFESTYLE AFFECT THE COURSE OF RHEUMATOID ARTHRITIS?

E. Atabekov[1], N. Shuvalova[2], S. Lezhenina[3], E. Guryanova[4,5]

[1]Bishkek State Hospital of Kyrgyz-Turkish Friendship named after Recep Tayyip Erdogan, Bishkek, Kyrgyzstan; [2]Chuvash State Pedagogical University named after I. Ya. Yakovlev, Cheboksary, Russia; [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia; [4]Federal State Budgetary Educational Institution of Higher Education "I. N.Ulyanov Chuvash State University, Cheboksary, Russia; [5]State Autonomous Institution of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic., Cheboksary, Russia

It involves a comprehensive approach that includes a balanced diet, regular physical activity, and other lifestyle changes. Although pharmacotherapy has achieved significant success, doctors set themselves a larger task: not only to suppress inflammation, but also to preserve the patient's functional independence as much as possible. In this context, physical therapy becomes an integral component of preventive and therapeutic programs. [1-5] Goal. To evaluate the effect of physical activity and nutrition on the frequency of rheumatoid arthritis attacks. Materials and methods. An observational prospective study was conducted on the basis of outpatient medical institutions in Kyrgyzstan in the period from October 2023 to October 2024. The study included a cohort of 80 patients with a verified diagnosis of rheumatoid arthritis (RA) that meets modern ACR/EULAR classification criteria and has a disease duration of more than 7 years. The criteria for non–inclusion were the presence of acute infectious diseases, severe uncontrolled somatic pathology (decompensated diabetes mellitus, heart failure of type III-IV), as well as contraindications to physical activity or refusal to participate. All patients were randomly assigned to two comparable groups: an experimental and a control group of 40 people each. The patients of the experimental group, in addition to the standard basic anti-inflammatory therapy (HDL), received a comprehensive non-drug intervention, which included: 1) swimming lessons (free swimming) 2 times a week for 40 minutes; 2) structured physical therapy sessions under the guidance of an instructor 2 times a week for 30 minutes (the exercise program has been adapted for the joints of the upper and lower extremities); 3) dietary correction with a daily calorie restriction of up to 1900 kcal and recommendations for limiting the consumption of red meat. Patients in the control group received only standard pharmacotherapy and were instructed to lead a normal lifestyle without additional interventions. The duration of the observation period and the use of non-medicinal methods was 12 months. To assess the impact of the intervention on the dynamics of the disease, a standardized questionnaire focused on assessing the frequency of RA exacerbations was conducted in all patients at the end of the study. The questionnaire included three dichotomous questions (yes/no answers): 1. Have you had an attack (exacerbation) of rheumatoid arthritis in the last two years? 2. Have you had an attack (exacerbation) of rheumatoid arthritis during the last year? 3. Has there been a deterioration in the course of this disease (have the attacks become more frequent) during the follow-up period? Statistical processing of the obtained categorical data was carried out in Statistical Analysis Software 17.0 using Analysis of Variance (ANOVA) to compare the proportions between groups. The level of statistical significance was set at $p<0.05$. Results. The gender distribution in the general sample (n=80) confirmed the predominance of women characteristic of RA: 52 patients (65%, 52/80) versus 28 male patients (35%, 28/80). The average age of the patients was 62 ± 2 years. The groups were representative and comparable in basic demographic and clinical parameters. According to the results of the 12-month follow-up, a statistically significant difference in the frequency of exacerbations between the groups was revealed. In the experimental group receiving complex non-drug therapy, 30 patients (75%, 30/40) had no exacerbations of RA during the last two years, which indirectly indicates stabilization of the condition during the intervention period. No exacerbations were observed in 8 patients (20%, 8/40) during the last year of the study. Only 2 patients (5%, 2/40) showed a subjective deterioration in the course of the disease with increased seizures (positive response to the 3rd question of the questionnaire). The opposite trend was observed in the control group, which received only standard therapy. An increase in RA attacks (positive response to question 3) was noted by 32 patients (80%, 32/40). At the same time, the presence of at least one exacerbation during the last year was confirmed by 8 patients (20%, 8/40), which indirectly indicates a higher overall frequency of exacerbations in this group compared with the experimental one. The intergroup differences in the distribution of responses to all three questionnaire questions were statistically significant ($p<0.001$). Conclusions. Comprehensive lifestyle modification, including regular physical therapy (2 times a week for 30 minutes), aerobic water exercise (pool access 2 times a week) and a calorie-restricted diet (up to 1,900 kcal / day) and red meat, significantly reduces the frequency of clinical exacerbations in patients with long-term rheumatoid arthritis. The results of the 12-month study demonstrate a statistically significant positive trend in the experimental group: 75% of patients did not have exacerbations during two years of follow-up, while 80% of patients in the control group experienced an increase in seizures.

The data confirm the expediency of non-drug programs in the standard treatment process to improve long-term disease control.

UNDERREPORTING OF VERTEBRAL FRACTURES: PREVALENCE AND PREDICTIVE FACTORS FROM THE VERTAIDO STUDY

E. Baldimtsi[1,2], M. Woisetschläger[1,3,4], T. Davidson[1], T. Bjerner[1,4,5], A. Spångeus[1,2,4]

[1]Department of Health, Medicine, and Caring Sciences, Linköping University, Linköping, Sweden; [2]Osteoporosis Outpatient Clinic, Clinical Department of Activity and Health in Linköping, Region Östergötland, Linköping, Sweden; [3]Clinical Department of Radiology in Linköping, Region Östergötland, Linköping; [4]Center for Medical Image Science and Visualization (CMIV), Linköping University, Linköping, Sweden; [5]Clinical Department of Radiology in Linköping, Region Östergötland, Linköping, Sweden

Objectives: This study aimed to identify clinical and radiology-related factors associated with the likelihood of VFs being reported in routine radiological reports compared with VFs detected using the FLAMINGO AI tool.
Materials and Methods: This observational study analyzed outcomes following clinical implementation of the FLAMINGO AI algorithm. The study cohort included patients aged >50 years who underwent CT examinations over a four-month period, and compared data from clinical routine reporting with the AI based and radiologist reevaluated data.
Results: During the study period, 3,971 unique individuals underwent CT examinations. The AI algorithm identified VFs in 566 patients (14%), all of which were subsequently confirmed by a radiologist. Among these 566 cases, VFs were documented in 229 radiology reports, corresponding to an overall reporting rate of 40.5%. Female patients were significantly more likely to be reported in radiology reports ($p = 0.008$), with a reporting rate of 45% among female patients compared with 33% among male patients. A significant association was also observed between referral unit and VF reporting. Reporting rates were highest for referrals from Primary Health Care (OR 3.59, $p < 0.001$), followed by Medicine (OR 2.67, $p = 0.001$) and the Emergency Department (OR 2.54, $p < 0.001$), compared with referrals from Surgery. Patients aged over 90 years had VFs reported more frequently than patients in younger age groups. Furthermore, if VFs had been described in previous radiology reports, they were more likely to be reported again in subsequent CT examinations ($p<0.001$).
Conclusions: Despite suboptimal overall reporting rates, this study identified several clinical factors significantly associated with increased reporting of VFs. Referral unit, advanced age, and prior documentation of VFs in earlier CT reports were all associated with higher reporting rates. These findings may increase physician awareness of factors contributing to VF underreporting.

TIMED UP AND GO TEST AND BONE MINERAL DENSITY MEASUREMENT WITH RADIOFREQUNCY ECHOGRAPHIC MULTISPECTROMETRY (REMS) IN OLDER FEMALES

E. Bischoff[1], F. Bischoff[2], S. Vladeva[3]

[1]Burgas State University "Prof. Dr. Assen Zlatarov" Burgas, Burgas, Bulgaria; [2]IPSMP Rheumatology, Stara Zagora, Stara Zagora, Bulgaria; [3]Trakia University, Department of Health Care, Faculty of Medicine, Stara Zagora, Stara Zagora, Bulgaria

Objective: The Timed Up and Go (TUG) test assesses mobility and fall risk, while bone mineral density (BMD) measurement is essential for osteoporosis evaluation. Traditional BMD assessment with DXA involves radiation, whereas radiofrequency echographic multi-spectrometry (REMS) provides a non-invasive, radiation-free alternative. This study aimed to examine the relationship between TUG performance and BMD using REMS.
Material and Methods: 120 women completed the TUG test, rising from a chair, walking three meters, turning, returning and sitting down. Times were recorded and participants classified into four groups: <10 s, 11–20 s, 21–29 s, and ≥30 s. REMS scans of the spine and hip were performed, and age, BMI, BMD and T-scores were compared across TUG groups using ANOVA. Data collection utilized a JAVA tool developed by Kirilov et al [1,2].
Results: 71 women (59.2%) completed TUG <10 s, 25 (20.8%) 11–20 s, 15 (12.5%) 21–29 s, and 9 (7.5%) ≥30 s. Women with TUG ≥30 s were older (85 y) and had lower BMI (24.4 kg/m²) than other groups ($p <0.001$). Spine BMD and T-scores decreased with longer TUG times: ≥30 s group had mean BMD 0.628 g/cm², T-score -3.3 SD versus <10 s group 0.842 g/cm², -1 SD ($p <0.001$). Hip BMD showed similar trends: ≥30 s group 0.445 g/cm², -3.6 SD versus <10 s 0.692 g/cm², -1.6 SD ($p <0.001$).
Conclusion: Slower TUG performance, particularly ≥30 s, is associated with lower spine and hip BMD and T-scores. Mobility assessment may help identify women at higher risk for osteoporosis and fractures, supporting early intervention.

IMPAIRED ORAL HEALTH PREDICTS FRACTURES AND FALLS IN OLDER ADULTS: A PROSPECTIVE COHORT STUDY

A. Kada[1], N. Chebib[2], M. Papageorgiou[1], M. Hars[1], A. Trombetti[1], S. Ferrari[1], F. Müller[2], E. Biver[1]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland; [2]Division of Gerodontology and Removable Prosthodontics, University Clinics of Dental Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland

Objective
The interplay between age-related declines in oral and musculoskeletal health, nutrition, and lifestyle in older adults remains poorly understood. The associations between oral health, fractures, falls, and lifestyle factors were investigated in a prospective cohort of older adults.
Methods
A total of 747 participants from the Geneva Retirees Cohort (mean age 67.9 ± 1.5 years; 80% women) were included with a mean follow up of 5.5 ± 1.8 years. Subjective oral health was assessed using the Geriatric Oral Health Assessment Index (GOHAI), a self-reported questionnaire covering functional, psychosocial, and pain/discomfort dimensions. In addition, number of teeth, presence of dental prostheses and/or implants and xerostomia were documented. Incident low-trauma fractures and non-traumatic falls were recorded. Bone density and body composition were assessed by DXA, bone microarchitecture and estimated bone strength by HR-pQCT with finite element analyses, and dietary intake using a food frequency questionnaire. All analyses were adjusted for age and sex.
Results
A total of 85 incident fractures and 230 individuals with at least one fall were recorded. Oral pain/discomfort and oral function impairment were associated with a higher risk of incident fractures (HR 95% CI per one-point decrease in GOHAI score, 1.18 (1.03, 1.35) and 1.09 (1.01, 1.18), respectively). The association of oral pain/discomfort was independent of hip BMD and FRAX. Teeth loss (<24 remaining teeth) and xerostomia were associated with an increased risk of falls (HR 1.53 (1.08, 2.16) and 1.69 (1.06, 2.7), respectively). Participants with teeth loss had lower trabecular density and reduced bone strength at the tibia. Participants with oral functional impairment and/or teeth loss had lower calcium and/or protein intakes, a higher BMI, lower physical activity levels, and a higher prevalence of smoking, without differences in muscle parameters.
Conclusion
Oral health may reflect musculoskeletal fragility beyond bone density measures and FRAX. Perceived pain and functional limitations were associated with an increased risk of fractures, while teeth loss and xerostomia were associated with falls. These associations appear partly related to nutrition and lifestyle factors, suggesting that maintaining a healthy lifestyle could improve both oral and musculoskeletal health. Supporting oral health in older adults may also contribute to support nutrition and a better musculoskeletal health.

P501

CIRCULATING DIPEPTIDYL PEPTIDASE-4 (DPP4): A NEW MARKER OF BONE FRAGILITY ASSOCIATED WITH INSULIN-RESISTANCE?

E. Biver[1], T. Ferguson[2], M. Hars[1], M. Papageorgiou[1], M. Gerbaix[1], S. Ferrari[1]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Genève, Switzerland; [2]ProAxsis Ltd, Building 75 Randox Science Park, 30 Randalstown Road, Antrim, N. Ireland, Antrim, Ireland

Objective
We investigated whether circulating DPP4 is associated with prevalent and incident fractures in older adults, according to insulin resistance (IR).
Methods
We studied 384 participants from the Geneva Retirees Cohort (mean age 67.9 ± 1.5 years, 80% women, 4% type 2 diabetes). IR was defined as HOMA ≥2.5 (27% of participants). A new ELISA was developed to quantify soluble DPP4 (Pro-axis Ltd, IR). Bone mineral density, turnover markers, and prevalent and incident low-trauma fractures (mean follow-up 6.1 ± 1.4 years) were assessed.
Results
DPP4 was higher in women (P = 0.003) and participants with osteoporosis (p = 0.015), but did not differ by diabetes, or IR. DPP4 correlated negatively with BMI (r = -0.22, p<0.001), spine and hip BMD (r = -0.17/-0.15, P=0.001/0.004), and positively with CTX and P1NP (r = 0.22/0.19; p < 0.001). IR participants were less often osteoporotic (9% vs 18%, P = 0.024) than non-IR participants, yet fracture prevalence (25% vs 23%, P = 0.652) and incidence (31 vs 22 per 1000 person-years, p = 0.164) were similar between groups. In age- and sex-adjusted models in IR participants, higher DPP4 was associated with a lower prevalence of fractures (OR per SD 0.59 [0.36–0.99]), notably in non-osteoporotic participants (OR 0.54 [0.32, 0.93]). However, DPP4 did not predict incident fractures. In non-IR participants, the highest compared with the middle DPP4 tertile was associated with a lower risk of prevalent (OR 0.20 [0.05, 0.87]) and incident fractures (HR 0.19 [0.04–0.96]) in osteoporotic participants.
Conclusion
Low circulating DPP4 is associated with higher BMI and BMD and lower bone turnover, -i.e. typical features of T2D, and with fractures in IR and osteoporotic non-IR participants. These data suggest that DPP4 could link metabolic disturbances with bone fragility. Whether DPP4 could serve as a predictor of fractures in diabetes requires further investigation.

P502

ASSOCIATION OF FRAILTY AND SARCOPENIA WITH AMYLOID POSITIVITY

E. Calluy[1], M. Locquet[2], O. Bruyère[3], J.-Y. Reginster[4], E. Cavalier[5], A. Ladang[5], C. Beaudart[6]

[1]Public Health Aging Research & Epidemiology (PHARE) Group, NAmur Research Institute for LIfe Sciences (NARILIS), University of Namur. Department of Clinical Chemistry, Centre Hospitalier Universitaire de Liège, University of Liège., Namur, Belgium; [2]Research Unit in Clinical Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Faculty of Medicine, University of Namur, 61, Rue de Bruxelles, 5000 Namur, Belgium., Namur, Belgium; [3]Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, Liège, Belgium; [4]Protein Research Chair, Biochemistry Department, College of Science, King Saud University, Riyadh, Kingdom of Saudi Arabia., Riyadh, Saudi Arabia; [5]Department of Clinical Chemistry, Center for Interdisciplinary Research on Medicines, Centre Hospitalier Universitaire de Liège, University of Liège, Rue de l'Hôpital 1, 4000 Liège, Belgium., Liège, Belgium; [6]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), NAmur Research Institute for LIfe Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium

Objective: The statistical association between multidimensional geriatric syndromes and amyloid positivity is not currently Yet, a better understanding of this clinical association could enable general practitioners to use easy-to-use tools to help with screening for cognitive decline. Using the Sarcopenia and Physical Impairment with advancing Age (SarcoPhAge) study, a Belgian cohort study including older adults, this study aims to evaluate if an association between the blood concentration of phosphorylated tau at position 217 (pTau217), a biomarker of amyloid positivity, and components of sarcopenia and frailty may exist.

Material and Methods: The concentration of pTau217 was measured in 218 plasma samples on Lumipulse platform at the second year of follow-up of the cohort. pTau217 was categorised according to recent literature in pTau 217 <0.13 pg/mL= amyloid-negative, pTau217= 0.13-0.39 pg/mL= possibly amyloid-positive, pTau217 >0.39 pg/mL= amyloid-positive. Sarcopenia and frailty components were evaluated and categorised according to the European Working Group on Sarcopenia in Older People (EWGSOP2) and Fried criteria, respectively.

Results: The 218 participants from the SarcoPhAge study had a median age of 73.96 years (interquartile range (IQR)= 69.57-78.49), 51% were women and the median concentration of pTau217 was 0.09 pg/mL (IQR=0.06-0.18). Based on predefined cut-offs, 140 participants were classified as amyloid-negative, 65 as possibly amyloid-positive, and 13 as amyloid-positive. Regarding geriatric status, 13 participants were sarcopenic, 9 were severely sarcopenic, 17 were frail, and 97 were pre-frail.

When all variables were analysed continuously, no significant correlations between pTau217 and handgrip strength, short physical performance battery (SPPB), gait speed, chair stand speed, appendicular lean mass and lean mass When categorised, sarcopenia and frailty, low gait speed, low SPPB, low muscle strength and low muscle mass in women were not significantly associated with pTau217 concentration (p>0.05). Additionally, the number of participants with amyloid positivity was not significantly higher in participants diagnosed with sarcopenia or frailty nor with participants with lower gait speed, lower SPPB, lower muscle mass or lower muscle strength (p>0.05).

Nonetheless, in addition to a significant association of pTau217 with Body Mass Index (BMI) (p=0.02), this study demonstrated a significantly correlation of pTau217 with fat mass (p<0.01). Moreover, low muscle mass was associated with higher concentrations of pTau217, but exclusively in men (p=0.006).

Conclusion(s): The clinical components of frailty and sarcopenia did not demonstrate an association with pTau217 in this study, suggesting that geriatric syndromes are not associated with cognitive decline. Nevertheless, it would be worthwhile investigating this association in a longitudinal study involving clinical evaluations of cognitive decline.

P503

FRACTURE RISK ASSESSMENT IN A COHORT OF 112 MALE PATIENTS UNDERGOING RADICAL CYSTECTOMY AND ILEAL URINARY DIVERSION

E. Casado[1], C. Eyre[1], C. Piqué[1], M. Cabanillas[1], J. Muñoz[2], C. Centeno[2], L. De Verdonces[2], L. Grubicy[3], A. Domínguez[2]

[1]Rheumatology Dpt. University Hospital Parc Taulí., Sabadell, Spain; [2]Urology Dpt. University Hospital Parc Taulí., Sabadell, Spain; [3]CETIR Centre Médic., Barcelona, Spain

Objectives

Radical cystectomy (RC) with ileal urinary diversion (UD) is the standard treatment for muscle-invasive bladder cancer. Although it improves oncological survival, metabolic acidosis and kidney failure, among other factors, may contribute to the loss of bone mineral density (BMD) and increase fracture risk. The aim of this study was to evaluate bone health and identify key risk factors associated with skeletal deterioration in these patients.

Matherial and Methods

This was a single-center, cross-sectional observational study. From January 2018 to April 2024, male patients over the age of 50 who underwent RC with ileal UD were consecutively enrolled, with a median follow-up of 35 months. Anthropometric data and biochemical parameters related to bone metabolism were collected. BMD was measured using a GE-Lunar iDXA densitometer. Vertebral fractures were assessed by VFA, and trabecular bone microarchitecture using TBS. The 10-year fracture risk was assessed using FRAX, adjusted for BMD and TBS.

Results

A total of 112 patients were included, with a median age of 71 years (IQR 64–77). The prevalence of osteoporosis and osteopenia was 32.1% and 43.8%, respectively. A total of 29.5% had a prior fragility fracture. Vertebral fractures were identified in 9.8% of the patients. A degraded TBS was observed in 40.2% of cases and partially degraded in 20.5%. The median FRAX score for osteoporotic major fracture and hip fracture was 3.9% and 1.35%, respectively. Patients with osteoporosis were older (OR = 1.11, 95% CI: 1.02–1.20; p = 0.012) and had a lower BMI (OR = 0.73, 95% CI: 0.62–0.86; p ≤ 0.001). Patients with degraded TBS had a higher BMI (OR = 5.23, 95% CI: 0.83–0.99; p = 0.041), higher creatinine levels (OR = 2.11, 95% CI: 1.08–4.11; p = 0.028), and more previous osteoporotic fractures (OR = 5.23, 95% CI: 2.08–13.13; p ≤ 0.001). Metabolic acidosis (16 patients) was not a risk factor for osteoporosis or degraded TBS.

Conclusions

Men undergoing UD after RC show a high prevalence of osteoporosis, deterioration of bone microarchitecture, and fragility fractures. Early

bone assessment using DXA and TBS is needed in these patients, along with preventive measures to reduce fracture risk.

P504

PERFORMANCE OF FRAX® TO GUIDE DXA USE AND ANTI-OSTEOPOROTIC TREATMENT IN MEN WITH ILEAL URINARY DIVERSION AFTER RADICAL CYSTECTOMY: UNDERESTIMATION OF FRACTURE RISK AND THE ADDED VALUE OF BMD AND TBS ADJUSTMENTS

E. Casado[1], C. Piqué[1], C. Eyre[1], J. Muñoz[2], C. Centeno[2], L. De Verdonces[2], M. Cabanillas[1], L. Grubicy[3], A. Domínguez[2]

[1]Rheumatology Dpt. University Hospital Parc Taulí., Sabadell, Spain; [2]Urology Dpt. University Hospital Parc Taulí., Sabadell, Spain; [3]CETIR Centre Médic., Barcelona, Spain

Objectives

Patients undergoing radical cystectomy (RC) with ileal urinary diversion (UD) have a fracture risk higher than the general population. This study aimed to determine whether FRAX® can reliably identify patients at risk of osteoporosis and help to guide treatment decisions in this population.

Material and Methods

We conducted a single-centre cross-sectional study including male patients aged >50 years who underwent RC with ileal UD between January 2018 and April 2024. BMD was measured using a GE-Lunar iDXA densitometer, TBS was derived to evaluate trabecular microarchitecture, and 10-year fracture risk was calculated using FRAX® (with and without BMD and TBS adjustment).

Results

A total of 112 men (median age: 71 years, IQR 64–77) with a median median follow-up of 34.8 months (IQR 14.2–85.6) were included. Osteoporosis and degraded TBS were found in 32.1% and 40.2% of patients, respectively. Median FRAX-MOF (major osteoporotic fracture) was 3.9% (IQR 2.7–6.05) without BMD, 5.3% (2.98–7.82) with BMD, and 5.8% (3.4–9.5) when adjusted for TBS. Median FRAX-Hip was 1.35% (0.7–2.78), 1.8% (0.9–4.55), and 2% (1–5.2), respectively. Receiver operating characteristic (ROC) analysis showed moderate discriminatory ability of FRAX without BMD to detect DXA-defined osteoporosis (AUC 0.716 for FRAX-MOF and 0.757 for FRAX-Hip) Optimal cut-offs were FRAX-MOF ≥4.6% (Sens 69.4%, Spe 72.4%, NPV 83.3%, PPV 54.3%) and FRAX-Hip ≥1.6% (Sens 77.8%, Spe 72.4%, NPV 87.3%, PPV 57.1%). Using these cut-offs, FRAX could potentially reduce the need for DXA screening up to 52.7%. Using the treatment thresholds recommended for the Spanish population (FRAX-MOF ≥10% or FRAX-Hip ≥3%, without BMD), 25% of patients would qualify for antiresorptive therapy. When incorporating TBS-adjusted FRAX® values (FRAX-MOF ≥7.5% or FRAX-Hip ≥3%), this proportion increased to 43.8%.

Conclusions

FRAX without BMD can be useful for identifying men with ileal UD after RC at risk of osteoporosis, potentially avoiding a substantial proportion of DXA. However, its moderate accuracy and tendency to underestimate the proportion of patients requiring antiresorptive therapy compared with DXA or BMD- and TBS-adjusted models highlight the need for a tailored fracture risk assessment strategy to enhance early detection and optimise bone-targeted treatment decisions.

P505

EGE FRACTURE LIAISON SERVICE: 3-YEAR FOLLOW-UP, PATIENT CLINICAL PROFILE AND SYSTEM EFFECTIVENESS

S. Koroglu[1], Y. Kirazli[1], K. Capaci[1], E. Cinar[1], S. Cesur[1], S. Ibrahim[1], K. Aktuglu[2]

[1]Ege University Hospital Department of Phsyical Medicine and Rehabilitation, Izmir, Türkiye; [2]Ege University Hospital Department of Orthopedic Surgery, Izmir, Türkiye

This study was conducted to evaluate the clinical profiles of patients followed at the Ege University Fracture Liaison Service and the effectiveness of the system. Osteoporotic fractures are known to cause significant mortality and morbidity in the elderly population. Therefore, the aim was to demonstrate the outcomes of the multidisciplinary approache in post-fracture management. A retrospective evaluation of 500 patients followed at the service between January 2021 and January 2025 was performed. Patient demographics, fracture locations, comorbidities, treatment methods, and mortality and morbidity rates were analyzed. Post-fracture functional status, use of assistive devices, and receipt of osteoporosis treatment were examined. 71.5% of the patients were female, 28.5% were male, and the mean age was 78.5 years. The most common fracture type was intertrochanteric (48.7%), and 95.8% of the fractures were due to falls. Surgical treatment was performed in 94.2% of patients, with intramedullary nailing being the most common method (63%). The mortality rate was 28.4%, and most deaths occurred within the first year after discharge. Significant deterioration in functional status was observed in patients after the fracture, with 53.4% becoming bedridden or having limited ambulation at home. Pharmacological treatment for osteoporosis was initiated in 40.2% after the fracture, with denosumab (60%) and zoledronic acid (27%) being particularly prominent. The findings indicate that osteoporotic fractures cause high mortality and morbidity in the elderly population and significantly reduce quality of life after the fracture. While the implementation of the liaison service has standardized patient evaluation, there is still room for improvement, particularly in initiating osteoporosis treatment and improving adherence. Disseminating fall prevention strategies, osteoporosis treatment, and patient-family education programs are critical to reducing post-fracture mortality and morbidity.

P506

DEFINING POPULATION AND SEX-SPECIFIC DXA-BASED THRESHOLDS FOR SARCOPENIC OBESITY IN AFRICAN ADULTS

E. De Lucia Rolfe[1], M. C. Pearce[1], A. M. Manyara[2], L. Micklesfield[3], E. I. Y. Madela[4], A. J. Burton[2], B. Cassim[4], I. Drammeh[5], H. Wilson[2], L. S. Gates[1], C. Grundy[6], R. Ferrand[6], C. L. Gregson[2], K. A. Ward[1]

[1]MRC Lifecourse Epidemiology, Human Development and Health University of Southampton, Southampton , United Kingdom; [2]Global Health and Ageing Research Unit, Bristol Medical School, University of Bristol, Bristol, UK, Bristol, United Kingdom; [3]University of the Witwatersrand, Johannesburg, South Africa; [4]University of KwaZulu-Natal, Department of Geriatrics, Durban, South Africa; [5]MRC Unit The Gambia at LSHTM, Fajara, Gambia; [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

Objectives
To derive population- and sex-specific DXA-based thresholds for sarcopenic obesity in African adults and examine their associations with physical function and metabolic outcomes, given that application of non-African thresholds is limited due to race and ethnic variation in body composition.
Methods
A population-based, cross-sectional study of adults aged ≥40 years from The Gambia, South Africa, and Zimbabwe, conducted as part of the MUFASSA study, with whole-body DXA available for The Gambia and Zimbabwe (n=3,160). Sex-specific reference distributions among adults aged 40–49 years defined high adiposity relative to muscle (trunk fat mass/appendicular lean mass [ALM] ≥+1 SD) and low muscle relative to body size (ALM/BMI ≤−2 SD; ALM/weight ≤−2 SD). Outcomes included low grip strength, slow gait speed, impaired chair rise, sarcopenia using population-specific thresholds (AFRO-SARC), and diabetes status (self-report, medication use, or elevated glucose). Logistic regression models were adjusted for age, sex, and study-sites; BMI was additionally included for trunk fat mass/ALM models. Sensitivity analyses confirmed consistency across study-sites.
Results
Thresholds were 0.52 in males (M) and 0.98 in females (F) for trunk fat mass/ALM; 0.82 (M) and 0.52 (F) for ALM/BMI; and 0.36 (M) and 0.27 (F) for ALM/weight. Overall prevalence of sarcopenic obesity was 15.6% for trunk fat mass/ALM, 6.2% for ALM/BMI, and 5.1% for ALM/weight, highest in Zimbabwe and lowest in rural Gambia. ALM/BMI showed the strongest and most consistent associations with low grip strength (OR 2.47, 95% CI 1.64–3.73), slow gait speed (OR 2.09, 95% CI 1.39–3.16), and AFRO-SARC sarcopenia (OR 2.03, 95% CI 1.03–4.00). For ALM/weight, adjusted ORs were 2.13 (95% CI 1.30–3.48) for low grip strength, 2.35 (95% CI 1.46–3.77) for slow gait speed, and 1.92 (95% CI 1.22–3.02) for diabetes status, whereas associations for trunk fat mass/ALM were attenuated after adjustment, except for diabetes status (OR 1.43, 95% CI 1.01–2.0).
Conclusions
Low muscle mass relative to body size identifies adverse physical function outcomes in African adults, with ALM/weight most strongly associated with diabetes status. The use of these sex-specific, population-derived thresholds enables accurate classification of sarcopenic obesity and supports improved identification of African adults with impaired physical function outcomes and adverse metabolic status.

P507

BARRIERS AND FACILITATORS TO WEIGHT BEARING SPORTING ACTIVITY IN YOUNG PEOPLE: CAN WE LEVER SOCIAL MEDIA TO HARNESS THE BENEFITS OF SPORT FOR OPTIMAL PEAK BONE MASS ACQUISITION?

H. Patel[1], M. Patel[2], L. Clark[3], H. Denison[4], P. Teesdale-Spittle[1], E. Dennison[1,5]

[1]Victoria University of Wellington, Wellington, New Zealand; [2]University of Otago, Dunedin, New Zealand; [3]Te Whatu Ora, Public Health Wellington, Wellington, New Zealand; [4]Massey University, Wellington, New Zealand; [5]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom

Objective
Participation in weight bearing sporting activity is a modifiable lifestyle factor that can be harnessed to improve peak bone mass during childhood and young adulthood. This study investigates the barriers and facilitators reported by young people regarding participation in such sporting activities.
Material and methods
Secondary school pupils in Aotearoa New Zealand were approached to participate using a convenience sampling approach. School principals and/or site co-ordinators gave verbal and written approval to conduct the study. There was no exclusion criteria. The main research question was: *"What are the barriers and enablers that you experience when engaging in sporting activity that is linked with bone health?* Focus groups were conducted using a semi-structured approach with open-ended questions and prompts. Transcripts were thematically coded by two coders in Nvivo using an inductive content analysis approach.
Results
Eight focus group discussions were held between March 2021 and November 2023, with 2 to 4 participants attending each group. The total sample size was 26 individuals (22 female, 4 male) ranging from 11 to 17 years of age, with a mean age of 14.46 (± 1.7). Ethnicity was reported as 13 European, 8 mixed Māori & Pacific people, 5 Asian and Indian origin The main barriers to sporting activity participation included transport constraints, fear of injury, long term impacts of the COVID-19 pandemic, financial restrictions, time management, negative perceptions relating to social media, gender disparity and stereotypes, family influences, and personal and cultural preferences. By contrast the facilitators cited were access to sporting activities, perception of furthering career pathways, encouragement and practical support, building and retaining friendships, benefits of social media, enjoyment, maintaining routines, keeping fit, feeling accomplished, and mental health benefits.
Conclusion
We found participation in weight bearing high impact sporting activity in school aged young people is influenced by many factors. The internet/social media was commonly mentioned as both a positive and negative factor regarding sporting participation. Educational interventions and positive role modelling using this medium might therefore improve sports participation in young people.

P508

METABOLIC–INFLAMMATORY LINKS TO BONE REMODELLING IN RHEUMATOID ARTHRITIS: HOMOCYSTEINE AND ADIPONECTIN RELATE TO THE RANKL/OPG AXIS

E. Deseatnicova[1], A. Tigulea[2], C. Bordeian[1], R. Usatii[2], E. Russu[1], L. Groppa[1]

[1]State Medical and Pharmaceutical University Nicolae Testemitanu, Chisinau, Moldova; [2]Clinican Republican Hospital, Chisinau, Moldova

Objective: To explore relationships between systemic inflammatory activity, homocysteine and adiponectin with DXA-derived bone density parameters and bone metabolism markers in RA.
Methods: Cross-sectional analysis of 170 RA patients. DXA was performed at the femoral neck, lumbar spine and distal radius. Serum cytokines (IL6, TNFα), homocysteine, adiponectin, RANKL and OPG were measured and the RANKL/OPG ratio was calculated. Associations were tested using Spearman's correlations (ρ); partial Spearman's correlations (rank-residual approach) adjusted for age and BMI were used for key metabolic mediator–bone marker relationships.
Results: Osteoporosis (any site) was present in 88.2%. Higher DAS28ESR correlated with lower femoral neck Tscore (ρ=−0.273, p=0.022) and radius Tscore (ρ=−0.290, p=0.016), BMD at the femoral neck, lumbar spine and radius (all p<0.05). In the biomarker subset, inflammatory cytokines were associated with a more osteoclastogenic profile: IL6 correlated positively with RANKL/OPG ratio (ρ=0.323, p=0.006) and inversely with OPG (ρ=−0.355, p=0.0026); similar patterns were observed for TNFα (all p<0.05). Adiponectin and homocysteine showed strong positive associations with RANKL and OPG (adiponectin–OPG ρ=0.682; homocysteine–OPG ρ=0.602; p<10⁻⁶) and inverse associations with the RANKL/OPG ratio (adiponectin ρ=−0.370, p=0.0016 and homocysteine). These associations remained significant after adjustment for age and BMI (adiponectin–OPG partial ρ=0.702, p<0.001; homocysteine–OPG partial ρ=0.628, p<0.001).
Conclusion: In RA, higher inflammatory disease activity is associated with lower DXA-derived bone density, while cytokine profiles relate to a higher RANKL/OPG ratio. Homocysteine and adiponectin are strongly linked to the RANKL/OPG system after adjustment for age and BMI, supporting a metabolic–inflammatory contribution to altered bone remodeling that may be only partly captured by DXA.

P509

ENDOCRINE CORRELATES OF BONE FRAGILITY IN RHEUMATOID ARTHRITIS: LINKS BETWEEN SEX HORMONES, RANKL/OPG AND FRAX

E. Deseatnicova[1], M. Curchi[1], A. M. Ambros[1], A. Nistor[1], L. Andries[1], L. Groppa[1]

[1]State Medical and Pharmaceutical University Nicolae Testemitanu, Chisinau, Moldova

Objective: To evaluate associations between sex hormones, RA duration and classical osteoporosis risk factors with DXA-derived T-scores, FRAX probability and bone metabolism markers.
Methods: Cross-sectional analysis of 170 RA patients. Variables included age, osteoporosis risk factors, serum 25(OH)vitamin D, FRAX and DXA T-scores. Serum FSH, LH, estradiol, progesterone, RANKL and OPG were measured and the RANKL/OPG ratio was calculated. The patients with any chronic conditions that may influence the results were excluded from the study. Associations were assessed using Spearman correlations. Severe osteoporosis was defined as a minimum T-score ≤ −3.5 at any site.
Results: Osteoporosis (any site T-score ≤ −2.5) was present in 88.2% and severe osteoporosis in 64.5%. Vitamin D deficiency was observed in 46.7%, lifetime glucocorticoid exposure - in 86.3%. RA duration correlated with higher FRAX hip probability (Spearman's ρ=0.293, p=0.00022) and lower femoral neck and lumbar spine T-scores (ρ=−0.326, p=0.00495; ρ=−0.317, p=0.0056). In the biomarker subset, RA duration correlated with higher RANKL (ρ=0.323, p=0.0064) and OPG (ρ=0.425, p=0.00025) and with a lower RANKL/OPG ratio (ρ=−0.322, p=0.0066). Higher FSH correlated with higher FRAX hip probability (ρ=0.488, p<0.001) and lower lumbar spine T-score (ρ=−0.376, p=0.0030). Estradiol correlated inversely with FRAX hip probability (ρ=−0.410, p=0.00051). Progesterone correlated inversely with RANKL (ρ=−0.385, p=0.0010) and positively with 25(OH)D (ρ=0.279, p=0.020). Severe osteoporosis was associated with older age (median 60 vs 52 years; p=0.00084) and longer glucocorticoid exposure (median 48 vs 12 months; p=0.0069).
Conclusion: In RA, disease duration and sex-hormone profiles correlate with osteoporosis severity, FRAX probability and modulation of the RANKL/OPG pathway, supporting a potential endocrine contribution to skeletal fragility alongside established risk factors such as age and glucocorticoid exposure.

P510

THE RELATIONSHIP BETWEEN XANTHIN OXIDOREDUCTASE COMPLEX ENZYMES ACTIVITIES AND ACTIVITY OF IMMUNOINFLAMMATORY RHEUMATIC DISEASES

E. E. Mozgovaya[1], S. A. Bedina[1], A. S. Trofimenko[1], S. S. Spitsina[1], M. A. Mamus[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Immune inflammation activity is one of the key characteristics of immunoinflammatory rheumatic diseases (IIRD). Xanthine oxidoreductase (XOR) is an important component of innate immunity which involved in IIRD pathogenesis. We aimed to study the dependence of XOR interconvertible forms (xanthine oxidase ((XO), EC 1.17.3.2) and xanthine dehydrogenase ((XDG), EC 1.17.1.4)) activities in plasma and lysed blood cells (WBC and RBC) on the disease activity of systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and systemic scleroderma (SSc) patients.

Methods: Diagnosis of RA was verified using the ACR/EULAR criteria (2010), SLE – EULAR/ACR criteria (2019), SSc – ACR/EULAR criteria (2013). Activities of XO and XDG were measured by spectrophotometric methods [1]. The enzymatic activities were expressed as nmol/min/ml and normalized to 1×10^7 cells/ml in WBC, to 1×10^9 cells/ml in RBC. The statistical relationships between variables were assessed using the Spearman rank correlation method (ρ). Differences were considered significant when p<0.05.

Results: 77 adult RA patients, 56 adult SLE patients and 51 SSc patients were enrolled in the study. The values of enzyme indicators depended

on the activity of the pathological process in all included in the study diseases: in RA (XO_{pl} (ρ=0.83, p<0.001); XDG_{pl} (ρ=-0.43, p<0.001); XO_{RBG} (ρ=0.81, p<0.001); XDG_{RBC} (ρ=-0.80, p<0.001); XO_{WBC} (ρ=-0.81, p<0.001); XDG_{WBC} (ρ=-0.80, p<0.001)); in SLE (XO_{pl} (ρ=0.88, p<0.001); XDG_{pl} (ρ=-0.88, p<0.001); XO_{RBG} (ρ=-0.81, p<0.001); XDG_{RBC} (ρ=0.75, p<0.001); XO_{WBC} (ρ=-0.83, p<0.001); XDG_{WBC} (ρ=-0.90, p<0.001)); in SSc (XO_{pl} (ρ=0.50, p<0.001); XDG_{pl} (ρ=0.74, p<0.001); XO_{RBG} (ρ=-0.84, p<0.001); XDG_{RBC} (ρ=-0.76, p<0.001); XO_{WBC} (ρ=-0.84, p<0.001); XDG_{WBC} (ρ=-0.83, p<0.001)). Unidirectional relationships were observed in plasma of RA and SLE patients; in lysed WBC of RA, SLE, and SSc patients.

Conclusion: The obtained results indicate the involvement of XOR in immune inflammation. The identified relationships suggest that XOR and XDG may be further studied as markers of immune inflammation activity.

P511

URIC ACID LEVEL IN IMMUNOINFLAMMATORY RHEUMATIC DISEASES

E. E. Mozgovaya[1], S. A. Bedina[1], A. S. Trofimenko[1], M. A. Mamus[1], S. S. Spitsina[1], I. A. Zborovskaya[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: We aimed to study assess the uric acid level in plasma of rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and systemic scleroderma (SSc) patients.
Methods: Diagnosis of RA was verified using the ACR/EULAR criteria (2010), SLE – EULAR/ACR criteria (2019), SSc – ACR/EULAR criteria (2013). The UA level was determined in plasma using the Müller-Seifert method and expressed in mmol/l. Data are presented as Me [Q25–Q75]. Differences in UA levels between groups were assessed using Mann-Whitney test and were considered significant when p<0.05.
Results: 77 adult RA patients (mean age 45 [37; 49] years); 56 adult SLE patients (mean age 35 [31; 42] years); 51 SSc patients (mean age 43 [38; 48] years) and 35 healthy volunteers (mean age 39 [34; 46] years) were enrolled in the study. UA level in group of healthy individuals was 0,30 [0,27–0,33]; in RA group - 0,34 [0,25–0,38]; in SLE group 0,34 [0,31–0,37]; in SSc group - 0,35 [0,33–0,36]. In contrast to the healthy individuals, UA levels were higher in plasma of all patient groups (all p<0.001). There were no significant differences in UA levels between all included in the study diseases (all p>0.05).
Conclusion: We have previously published the results of studies confirming an increase in the prooxidant potential of plasma due to the implementation of all XOR activities in RA, SLE and SSc [1,2]. According to literature data, UA accounts for approximately half of the human plasma antioxidant activity [3]. Increasing UA levels may help protect cellular structures from the damaging effects of free radicals in RA, SLE and SSc.

P512

AGE-RELATED VARIATIONS IN WHOLE-BODY AND REGIONAL BODY COMPOSITION WITHIN HEALTHY, OVERWEIGHT AND OBESE BMI CATEGORIES IN ADULT MALES

E. F. Fellows[1]

[1]Unitversity of Nottingham, Nottingham, United Kingdom

Objective
This study aimed to investigate whether absolute (g) whole-body and regional body composition differ with age in adult males.
Material and Methods
This cross-sectional study harvested data from 1065 individuals using dual-energy X-ray absorptiometry (DEXA) which accurately measured whole-body fat mass (WBFM), whole-body lean mass (WBLM), leg fat mass (LFM), leg lean mass (LLM), android (abdominal) fat mass (AFM), and whole-body bone mineral density (WBBMD). Age groups were younger (18-40), middle-aged (41-64), and older (65+). Data for 381 males were matched according to their BMI group: healthy, overweight, and obese. Each BMI group was analysed separately. Statistical analysis was performed using Two-way Analysis of Variants (ANOVA) and the Kruskal-Wallis test.
Results
LFM in the obese weight BMI category and AFM in the overweight BMI category showed that LFM was lower, and AFM was higher in the older and middle-aged group compared to the younger group. There was no difference observed in WBFM across the age groups. The healthy weight BMI category showed that WBLM and LLM were lower in the older age group compared to the younger group. No significant difference in WBBMD was found across the age groups.
Conclusions
Fat mass demonstrated region-specific changes with age, with increases and decreases observed across the android and leg regions, respectively. This suggested that fat mass may increase and decrease within different regions of the body simultaneously as we age. Lean mass showed a decline with age, particularly in the later stages of ageing. In contrast, whole-body bone mineral density (WBBMD) remained relatively stable across age groups, suggesting that lifestyle and environmental factors may play a more influential role than age alone in determining bone mineral outcomes.

FIBROMYALGIA IN REAL CLINICAL PRACTICE

E. Filatova[1], A. Karateev[1], O. Teplyakova[2], S. Yakupova[3], S. Lapshina[3], E. Trofimov[4], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Ural State Medical University, Ministry of Health of Russia, Yekaterinburg, Yekaterinburg, Russia; [3]Kazan State Medical University Russian Federation, Kazan, Russia; [4]North-Western State Medical University named after I.I. Mechnikov, Ministry of Health of Russia, Saint Petersburg, Russia

Fibromyalgia (FM) is a chronic syndrome characterized by pain, fatigue, and other somatic symptoms. Not only does it significantly impact the quality of life of patients with rheumatic diseases, but it also often prevents them from achieving remission.

Objective: to assess the frequency of FM in real clinical practice among patients with confirmed rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) and its impact on key indicators.

Material and Methods: the study included 30 patients with RA, 33 with AS, and 23 patients with PsA. The diagnostic criteria for FM, as formulated by the American College of Rheumatology in 2016 (ACR2016), were uniformly applied to all patients enrolled in the study. To be diagnosed, pain lasting more than 3 months, generalized pain syndrome, a widespread pain index (WPI) WPI ≥ 7 or WPI 4–6, and a symptom severity scale (SSS) WPS ≥ 5 or SSS ≥ 9 were required.

Result: The main characteristics of the patients included in the study are presented in the table 1.

Table 1. Characteristics of patients included in the study

Parameters	RA (n=30)	AS (n=33)	PsA (n=23)
Gender	M –6; W - 24	M-19; W-14	M – 14; W - 9
Age	53.0[47.5;59.0]	42.0[38.0;51.0]	46.0[38.0;5.5]
Height	68.9[60.5;83.0]	78.0[63.0;90.0]	85.2[71.9;99.0]
Weight	164.0[160.5;171.5]	174.0[164.0;180.0]	171.0[163.5;180]
BMI	26.5[22.67;28.8]	26.2[22.3;29.3]	27.9[24.7;29.5]
Duration of illness	6.5[4.0;15.0]	5.0[3.0;10.0]	5.0[3.0;10.0]

Using the 2016 FM diagnostic criteria, FM was found to be present in 26.6% of patients with RA, 23.5% with AS, and 17.4% with PsA. Moreover, its presence is characteristic of patients with more severe pain according to the VAS scale, a significantly higher number of painful joints, anxiety disorders, and more severe functional impairments.

Conclusion. Given the high prevalence of FM in patients with RA, AS and PsA, individuals presenting with severe pain, a high number of tender joints, emotional disturbances, and a suboptimal response to therapy should be evaluated for the presence of FM.

P514

PORTRAIT OF A PATIENT WITH FIBROMYALGIA

E. Filatova[1], A. Karateev[1], O. Teplyakova[2], S. Yakupova[3], S. Lapshina[3], E. Trofimov[4], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Ural State Medical University, Ministry of Health of Russia, Yekaterinburg, Yekaterinburg, Russia; [3]Kazan State Medical University Russian Federation, Kazan, Russia; [4]North-Western State Medical University named after I.I. Mechnikov, Ministry of Health of Russia, Saint Petersburg, Russia

Objective: To study the characteristics of patients suffering from fibromyalgia.

Methods: the study encompassed 86 patients diagnosed with confirmed rheumatological diseases, including rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). All patients were examined using the FM criteria of the American College of Rheumatology (ACR 2016), and additional parameters such as educational attainment, marital status, employment status, and the presence of an association between disease onset and a self-reported stressful event were documented. Additionally, the study incorporated 39 patients without a rheumatological diagnosis who met the ACR 2016 FM criteria.

Result: FM was identified in one-third of patients with rheumatological diseases, with prevalence rates of 26.6% in RA, 23.5% in AS and 17.4% in PsA. In addition to significantly higher Visual Analog Scale (VAS) pain scores, a greater number of tender joints, and correspondingly elevated rheumatological diseases disease activity indices, patients with FM were more frequently single or divorced, had a general or incomplete higher education level, and experienced partial, remote employment, or job termination. Over 60% of patients with FM reported associating disease onset with prior stress exposure. The same clinical profile was observed in patients with FM without rheumatological diseases.

Conclusion. The clinical features of a patient with fibromyalgia encompass not only the presence of chronic generalized pain syndrome, elevated rheumatic disease activity indices, and diminished quality of life but also potentially a distinct clinical profile. A patient with FM is more frequently a single individual with an average educational attainment, prone to occupational shifts toward part-time employment, and exhibiting heightened anxiety levels.

P515

FIBROMYALGIA IN RHEUMATIC DISEASES: INFLUENCE ON THE ASSESSMENT OF DISEASE ACTIVITY

E. Filatova[1], A. Karateev[1], O. Teplyakova[2], S. Yakupova[3], S. Lapshina[3], E. Trofimov[4], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Ural State Medical University, Ministry of Health of Russia, Yekaterinburg, Yekaterinburg, Russia; [3]Kazan State Medical University Russian Federation, Kazan, Russia; [4]North-Western State Medical University named after I.I. Mechnikov, Ministry of Health of Russia, Saint Petersburg, Russia

Objective: to determine the effect of FM on disease activity and treatment choice in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Material and methods: the study included patients with reliable diagnoses of RA, AS and PsA. FM was diagnosed according to the criteria of the American College of Rheumatology in 2016 (ACR2016). The main characteristics of patients, indicators of disease activity (DAS28, BASDAI) were recorded and compared, and patient treatment tactics were analyzed.
Results: The study enrolled 86 patients with rheumatoid arthritis (RA, n=30), ankylosing spondylitis (AS, n=33), and psoriatic arthritis (PsA, n=23). Fibromyalgia (FM) was identified in 26.6% of RA patients, 23.5% of AS patients, and 17.4% of PsA patients. Demographic characteristics were comparable across groups, except for sex distribution, with a predominance of women in the FM group. Disease activity scores were significantly higher in FM patients within the RA group (DAS28 index: 5.2 [4.38; 6.9] vs. 3.5 [2.8; 5.4], p=0.03) and the PsA group (BASDAI: 7.2 [6.3; 8.3] vs. 4.3 [2.8; 6.2], p=0.02). In the AS group, scores differed but did not reach statistical significance (BASDAI: 5.4 [4.75; 6.45] vs. 4.8 [3.0; 5.8], p=0.2), potentially due to the small sample size. No differences in inflammatory markers were observed based on FM presence or absence. Analysis of treatment regimens revealed a higher percentage of patients receiving bDMARDs in the FM groups.
Conclusion: Fibromyalgia is a common comorbid condition in patients with RA, AS, and PsA. The presence of FM may affect disease activity index scores, which can lead to incorrect treatment strategies and unwarranted intensification of therapy.

P516

REAL-WORD USE OF ABALOPARATIDE IN WOMEN WITH SEVERE OSTEOPOROSIS: PATIENT PROFILE, TREATMENT PERSISTENCE AND EARLY DENSITOMETRIC OUTCOMES FROM A SPANISH TERTIARY HOSPITAL

E. Flores-Fernandez[1], P. Andujar-Brazal[1], L. Montolio-Chiva[1], A. Lozano-Saez[1], A. Conesa-Mateos[1]

[1]Universitary General Hospital of Castellon, Castellon de la Plana, Spain

Objectives
To describe the clinical characteristics, treatment persistence, safety profile and early densitometric changes in a single-centre cohort of Spanish patients with osteoporosis initiating treatment with ABL.

Methods
A retrospective single-centre descriptive study was conducted between May 2024 and December 2025 including patients treated with ABL in a tertiary Spanish hospital. Statistical analysis was performed using SPSS version 21.0.

Results
A total of 43 women were included in the study. The median age was 66 years [IQR 60–74]. At least one previous fracture was present in 68,3% of patients, with a mean number of 1,76 fractures per patient (SD 2,00). Regarding fracture type, vertebral fractures were the most frequent (60,5%), followed by wrist fractures (11,6%) and hip fractures (9,3%). Several patients presented with fractures at more than one site. Regarding previous osteoporosis treatments, oral bisphosphonates were the most frequently used (31%), followed by denosumab (19%) and teriparatide (12%). Baseline densitometry showed severe osteoporosis, with a mean T-score of −3,35 ± 0,82 SD at the lumbar spine, −2,34 ± 0,74 SD at the femoral neck and −2,25 ± 0,88 SD at the total hip. The median treatment duration was 272 days [IQR 92–344]. During follow-up, 12 patients (27,9%) discontinued treatment, predominantly early after treatment initiation. Discontinuations were attributed to mild adverse events in 8 patients and to the patient's own decision in 4 patients. No serious treatment-related adverse events were observed. In the small subgroup of patients with follow-up densitometry available (n=3), a trend towards improvement in T score was observed, with a mean relative increase of 12,9% at the femoral neck and 89,7% at the total hip compared with baseline, while changes at the lumbar spine were minimal. However, the very limited sample size precludes definitive conclusions.

Conclusions
This single-centre real-world study shows that ABL is mainly initiated in women with severe osteoporosis and high fracture burden. No fractures were recorded during follow-up. Discontinuations were mostly driven by patient decision or mild adverse events, and early densitometric improvements were observed in a small subgroup of patients specially in femoral neck and total hip.

P517

USE OF CINACALCET IN SECONDARY HYPERPARATHYROIDISM IN HEREDITARY HYPOPHOSPHATEMIC RICKETS

E. G. Giacoia[1], M. C. B. Balonga[1], S. T. Tormo[1], M. S. K. Kastelic[1], M. V. F. Forclaz[1]

[1]Hospital Posadas, Buenos Aires, Argentina

Introduction: X-linked hypophosphatemic rickets (XLH) is a rare disease caused by variants in the PHEX gene.Secondary and tertiary hyperparathyroidism have been described in these patients; among the possible causes are treatment with phosphate salts, deficient calcitriol production due to excess FGF23, and parathyroid resistance to the action of FGF23.

We present the case of a patient treated with burosumab plus calcitriol for the management of hyperparathyroidism secondary to XLH.

A 20-year-old patient has been under follow-up since birth for X-linked hypophosphatemic rickets. His mother, grandmother, and maternal aunt all have the same condition. He began conventional treatment with phosphate salts and calcitriol until age 11. From birth, the patient presented with elevated PTH levels and calcium levels at the upper limit of normal. He started burosumab 0.8 mg/kg subcutaneously every 14 days with clinical success, correction of bone deformities, improvement in pain, and school attendance appropriate for his age. He began participating in sports. At age 17, he began the transition process, during which an increase in calcium and PTH levels was observed. He weighed 66 kg, was 154.7 cm tall, and a renal ultrasound revealed mild nephrocalcinosis. The burosumab dose was reduced to 50 mg/kg every 28 days. Calcium levels stabilized until age 20, at which point they began to rise again. Initiate cinacalcet 30 mg orally every 12 hours.

	Birth (4 months)	3 years old	16	17	18	19	20
Calcium (8.2 a 10.3 mg/Dl)	10.1	10.5	11.2	10.4	9.5	10.7	9.7
Fosfato (2.5-4.5 mg/Dl)	3.1	2.6	2.3	3.7	2.5	2.1	2.9
PTH (15-65 pg/ml)	70	140	218	156	153	209	103
Vitamina D ng/ml	19		43	25			32

Conclusion:

The prevalence of secondary and tertiary hyperparathyroidism was 25% and 10% respectively in XLH[2]. Evaluation of the parathyroid axis is necessary from the time of diagnosis of the disease, as well as its treatment, to avoid associated complications.

Treatment with cinacalcet in combination with burosumab minimized the risk of hypercalcemia and nephrocalcinosis and prolonged the time on medical treatment until parathyroid surgery.

P518

SEVERE EARLY-ONSET OSTEOPOROSIS IN A YOUNG MALE WITH ANKYLOSING SPONDYLITIS TREATED WITH SECUKINUMAB AND GLUCOCORTICOIDS

E. Guci[1], A. Gremi[1]

[1]Qendra Spitalore Universitare Nene Tereza, Tiranë, Albania

Objective: To describe severe secondary osteoporosis in a young male with ankylosing spondylitis (AS) and to emphasize the importance of early bone density assessment in patients with inflammatory spondyloarthritis receiving long-term immunomodulatory and glucocorticoid therapy.
Methods: A 31 year old HLA-B27–positive male with ankylosing spondylitis underwent longitudinal laboratory assessment and dual-energy X-ray absorptiometry (DEXA). Inflammatory markers, complete blood count, liver enzymes, ferritin, coagulation markers, autoimmune serology, and procalcitonin were evaluated. Bone mineral density (BMD) was measured at the lumbar spine (L1–L4) and right femur. Fracture risk was assessed using FRAX. Anthropometric data were recorded. Current treatment included secukinumab; previous exposure to systemic glucocorticoids was documented.
Results: Marked systemic inflammation was observed with C-reactive protein up to 119.3 mg/L, erythrocyte sedimentation rate up to 112 mm/h, leukocytosis up to 22.9 K/μL with neutrophilia and immature granulocytes, and ferritin up to 518.5 ng/mL. Mild transaminase elevation was present. Procalcitonin remained low, excluding bacterial infection. Rheumatoid factor and anti–cyclic citrullinated peptide antibodies were negative. DEXA demonstrated severe osteoporosis: lumbar spine BMD 0.815 g/cm² (T-score −3.4) and right femoral neck BMD 0.633 g/cm² (T-score −3.4; Z-score −2.8). Ward's region T-score reached −3.6. Multiple fracture risk factors were identified, including inflammatory disease, smoking, alcohol intake, family history of hip fracture, prior glucocorticoid exposure. The patient received systemic corticosteroid therapy (prednisone) and disease-modifying treatment with clinical improvement.. Alendronate plus cholecalciferol 70mg/5600IU 1 capsule a week was added to the therapy considering the high risk of fracture. As the inflammatory markers lowered the prednisone dose was reduced to a minimum in ordered to establish minimum disease activity.
Conclusions: Young patients with ankylosing spondylitis may develop severe early osteoporosis due to chronic inflammation and cumulative risk factors. Early DEXA screening and aggressive bone-protective strategies should be integrated into the management of high-risk patients.

P519

NEUROPROTECTIVE EFFECTS OF ESTROGEN REPLACEMENT THERAPY IN AN ALZHEIMER'S DISEASE MOUSE MODEL ACROSS DIFFERENT LIFE STAGES

P. Juarez Camacho[1], E. H. Novoa Tanaka[1], H. Hermosillo Gutierrez[1], J. A. Betancourt-Valencia[1]

[1]Universidad Autonoma de Guadalajara, Guadalajara, Mexico

Objective(s)
To compare the neuroprotective effects of estrogen replacement therapy (ERT) on Alzheimer's disease (AD) pathology and cognition when initiated at different life stages in a mutant mouse model.
Material and Methods
Randomized controlled longitudinal experiment in 20 female APP-mutant C57BL/6 mice, aged 4–14 months. Animals will be allocated to four groups (n=5): control (no ERT), early ERT starting at 4–6 months (premenopausal equivalent), intermediate ERT starting at 8–10 months after ovariectomy (early postmenopause), and late ERT starting at 12–14 months after ovariectomy (late postmenopause). 17β-estradiol or vehicle will be administered for two weeks. Primary outcomes are amyloid plaque load and neurofibrillary pathology (immunohistochemistry), neuronal density in hippocampus and cortex, and cognitive performance in the Morris water maze. Group differences will be analysed with ANOVA (SPSS).
Results
As this is an ongoing protocol, no experimental data are yet available. We hypothesize that early ERT will reduce amyloid plaque burden, neuronal loss and cognitive decline compared with control, whereas late initiation will show attenuated or absent neuroprotective effects.
Conclusion(s)
As this is a protocol-based submission, no data-driven conclusions can yet be drawn. However, the proposed experimental design is expected to determine whether the timing of estrogen replacement therapy initiation influences amyloid burden, neuronal loss and cognitive decline in an Alzheimer's disease mouse model, thereby providing mechanistic support for or against the "critical window" hypothesis.

P520

IS ORAL HEALTH ASSESSMENT TOOL BETTER THAN HAND GRIP STRENGTH TO PREDICT COMPLICATIONS AFTER HIP FRACTURE? PRELIMINARY RESULTS

H. Gutierrez Hermosillo[1], E. H. Novoa Tanaka[2,3], J. L. A. Morales Torres[3,7], A. Navarro Sotelo[4], N. Compean Villarreal[5], E. Diaz de Leon Gonzalez[6]

[1]Escuela Nacional de Estudios Superiores, Unidad Leon, Universidad Nacional Autonoma de Mexico, Leon, Mexico; [2]Universidad Autonoma de Guadalajara, Guadalajara, Mexico; [3]Hospital Aranda de la Parra, Leon, Mexico; [4]Cirugia de Pelvis y Acetabulo, UMAE Bajio 1, Instituto Mexicano del Seguro Social, Leon, Mexico; [5]Departamento de Geriatria Hospital Aranda de la Parra, Leon, Mexico; [6]Instituto Mexicano del Seguro Social, Monterrey, Mexico; [7]Centro de Investigacion Morales Vargas, Leon, Mexico

Objective.
The primary objective is to compare the effectiveness of OHAT vs HGS to identify complications after hip fracture.
Material and methods
This is a prospective cohort study, in patients with hip fracture in the Hospital Aranda de la Parra, in Leòn, Mèxico. They are invited to participate, previous informed consent (either provided by the patient or, in case of dementia, the caregiver), once the diagnosis is confirmed by the orthopedic surgeon, they are included in the study; besides of regular medical history and sociodemographic approach, clinimetric variables were evaluated as well as physical exam, HGS was measured with a hydraulic Jamar dynamometer, and OHAT is applied to each patient, both by a trained physician, all laboratory results prior surgery are recorded, they will be followed up at 1 and 12 months after surgery. The study was evaluated and approved by the local Ethics and Research Committee.
Results
Currently 6 patients are included, all women, average age is 87, 1 with previous diagnosis of osteoporosis, Charlson index 4.2 Barthel Index 79.2, FRAIL 3.2. HGS 11 OHAT 5.7, 25HO Vitamin D 18.8 ng/ml, 3.2 length in hospital, only 1 has required transfusion (2 units) none of them has had delirium.
Conclusion
These are preliminary results, we can see that the HGS is very low, and the OHAT is high among these patients, only 1 patient has had complications, these results will change once the work is complete.

P521

CARDIOVASCULAR SAFETY OF ROMOSOZUMAB IN POSTMENOPAUSAL WOMEN WITH SEVERE OSTEOPOROSIS: INTERIM RESULTS FROM A EUROPEAN MULTI-DATABASE POST-AUTHORISATION SAFETY STUDY

T. Rathod-Mistry[1], M. T. Sanchez-Santos[1], E. H. Tan[1], C. Reyes[2,3], M. Far[3], J. Reinold[4], L. Pederson[5], B. Darvalics[5], K. Verhamme[6], A. Brutau Abia[7], F. Riefolo[7], P. Beukelaers[8], S. Lisart[8], A. Moayerri[9], D. Prieto-Alhambra[1]

[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]EAP Sardenya-Research Institute Sant Pau (EAP Sardenya-IR Sant Pau), Sardenya Primary Health Care Center, Barcelona, Spain; [3]Fundació Institut Universitari per a la Recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain; [4]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Department of Clinical Epidemiology, Bremen, Germany; [5]Aarhus University Hospital and Aarhus University, Department of Clinical Epidemiology, Aarhus, Denmark; [6]Erasmus MC, Department of Medical Informatics, Rotterdam, Netherlands; [7]Teamit Institute, Partnerships, Barcelona, Spain; [8]UCB, Brussels, Belgium; [9]UCB, Slough, United Kingdom

Objective(s): Romosozumab is approved for treatment of severe osteoporosis (OP) in postmenopausal women at high risk of fracture. A European post-authorization safety study has been implemented within the Risk Minimization Plan to evaluate the risk of serious cardiovascular (CV) events under real-world conditions. This interim analysis evaluates the safety of romosozumab compared to other OP treatments (including alendronate as main comparator) for outcomes of serious CV events (myocardial infarction [MI], stroke), cardiac arrhythmias, all-cause mortality, and CV death.
Materials and Methods: This European multi-database, new user active comparator cohort study used routinely collected healthcare data (Jan 2018–Jan 2025 for this interim analysis) from Denmark, Germany, the Netherlands, Spain, and the UK. The primary outcome was a composite of major adverse CV events (MACE-2: MI, stroke, all-cause mortality) within 12 months of treatment initiation. Propensity score matching (1:3) was applied to control confounding between romosozumab and alendronate users. Hazard ratios (HRs) and 95% confidence intervals (CIs) for MACE-2 and secondary outcomes were estimated using Cox regression and random-effects meta-analysed across databases. Sensitivity analyses included negative control outcomes, self-controlled case series, and instrumental variable analyses.
Results: This interim analysis contains 1,900 eligible romosozumab and 312,410 alendronate users. Too few MACE-2 and secondary events (i.e. 0 or <5) occurred among romosozumab users in four databases to estimate incidence rates. In Germany, MACE-2 incidence for romosozumab was 15.7 (95% CI: 6.3–32.4) vs. 28.2 (26.7–29.8) per 1,000 person-years for alendronate. In matched cohorts (1,763 romosozumab vs. 4,671 alendronate users), meta-analysis showed HR of 0.57 (95% CI: 0.31–1.03) for MACE-2. Majority of MACE-2 composite outcomes were all-cause mortality, and secondary outcomes (MI and stroke) could not be compared due to low numbers in romosozumab users.
Conclusions: Current interim data has not identified any clear difference in MACE-2 events between romosozumab and alendronate in European practice, though low number of events limit certainty. Final results with more data are expected next year for definitive conclusions.

CLINICAL ASPECTS OF DYSMORPHOGENETIC SYNDROMES: THE RESEARCH OF PHENOTYPES OF STUDENTS

E. Ibragimova[1], G. Reshetnik[2]

[1]Crimean Engineering and Pedagogical University named after FevziYakubov, Simferopol, Russia, [2]V. I. Vernadsky Crimean Federal University, Simferopol, Russia

Purpose: Genetic variations in the process of morphogenesis and development of connective tissue (CT) entail functional and structural abnormalities, namely connective tissue dysplasia (CTD), which necessitates the study of phenotypic markers of CTD.
Methods: The phenotypic marker of CTD is hypermobility syndrome (HMS) caused by an autosomal dominant type of inheritance. The HMS assessment was carried out on the Beighton score (9 points). The degree of hypermobility was classified as generalized (GHM, 9 points), severe (SHM, 5–8 points) or mild (MHM, 3–4 points). Joint hypermobility syndrome (JHS) itself was diagnosed in the presence of one or more of the following clinical markers: passive little finger bending backward >90°, thumb touching the forearm, elbows/knees bending backward>10°, and the ability to reach the floor with the palms of the hands when bending with straight legs. The obtained results were processed using mathematical statistics methods in the Excel program. The Student's t-test was used to assess the reliability of the data obtained.
Results: The results of the observations showed that signs of CTD were detected in 60% (n=63) of the participants, while the average number of signs observed in one person was 3.17±0.52.
63 students participated in the survey. 39 different types of CTD were identified, localized in various anatomical and topographic areas of the body. The identified symptoms were classified into two groups: major (joint hypermobility (JHM), skin hyperelasticity, chest deformity, and others) and minor (microanomalia). The analysis showed that of the students with CTD (n=63), the major signs were found in only 25 participants, 38 had only minor signs.
Conclusion: The results obtained emphasize the wide polymorphism of the phenotypic manifestations of CTD. A combination of various malformations, such as malformations of the heart, deformities of the chest and back, curvature, long trunk, arachnodactylia, striae and platypodia, with joint hypermobility (JHM), was revealed.

P525

DENOSUMAB FOR THE TREATMENT OF OSTEOPOROSIS IN HONG KONG CHINESE WOMEN: COMPLIANCE, EFFICACY AND ADVERSE EVENTS

E. Lau[1], D. Lam[2]

[1]Hong Kong Center for Clinical Research, Hong Kong, Hong Kong SAR China; [2]Hong Kong Orthopaedic and Osteoporosis Center for Treatment and Research, Hong Kong, Hong Kong SAR China

Objectives
To study the followings for denosumab in treating Chinese women with osteoporosis:

- Efficacy in increasing bone mineral density
- Compliance to treatment
- Adverse events

Material and methods
Six hundred and fifty-five postmenopausal women with osteoporosis or osteopenia with major risk factors, or fracture history were recruited. Subjects were treated by Denosumab injection every 6 months. Bone mineral density (BMD) was measured by Dual X-Ray densitometry (DEXA). Subjects were followed up for 5 years.

Results
A total of 655 subjects were recruited in the whole study for compliance, and 283 subjects participated in the DEXA study. The BMD increase is shown in the table. The percentage increase was comparable to international trials e.g. The Freedom Study. The compliance dropped quite rapidly and was 49% for the fifth injection; and 15% for the 11 injections.
No osteoporosis of the jaw nor atypical femoral fracture were observed. One patient developed skin reaction which led to discontinuation of treatment.

Conclusion
Denosumab is a safe and efficacious drug for treating osteoporosis in Chinese women. Efforts should be made to increase long term compliance.
Percentage change (mean±SD) in BMD at the total hip and total spine

	1st year 6 months after 2nd injection (N=283)	3rd year 6 months after 6th injection (N=144)	5th year 6 months after 10th injection (N=63)
Total hip BMD (gm/cm^2)	0.730±0.094	0.738±0.098	0.736±0.096
Percentage change from baseline	2.69±2.55	4.90±3.20	6.99±3.68
Total spine BMD (gm/cm^2)	0.832±0.100	0.838±0.091	0.860±0.091
Percentage change from baseline	4.33±4.18	7.20±5.31	10.08±7.09

P526

FROM MORTALITY TO DISABILITY: THREE DECADES OF CHANGING BURDEN OF RHEUMATOID ARTHRITIS IN ECUADOR

E. Lopez Gavilanez[1], L. Imaicela Naula[2], M. Navarro Grijalva[3]

[1]AECE Research Group. The Association of Clinical Endocrinologists of Eduador, Guayaquil, Ecuador; [2]Aece Research Group. The Association of Clinical Endocrinologist of Ecuador, Guayaquil, Ecuador; [3]AECE Research Group. The Association of Clinical Endocrinologists of Ecuador., Guayaquil, Ecuador

Rheumatoid arthritis (RA) is a significant cause of chronic disability and global health burden. In Ecuador, longitudinal information on the evolution of the burden of RA is limited, which hinders the planning of specialized services and evidence-based health policies.

Objectives

Describe temporal changes in mortality, incidence, prevalence, and disability-adjusted life years (DALYs) due to RA in adults ≥35 years of age in Ecuador between 1990 and 2021, evaluating age-standardized rates and trends using Joinpoint models.

Materials and methods

Data from the Global Burden of Disease 2021 for Ecuador were analyzed. Absolute numbers and age-standardized rates of mortality (ASDR), incidence (ASIR), prevalence (ASPR), and DALYs (ASYR) were estimated, stratified by sex. Temporal trends were evaluated using Joinpoint models.

Results

Between 1990 and 2021, in Ecuador, the incidence increased from 507.1 to 2,277.2 per 100,000 inhabitants, and the prevalence from 9,151.3 to 43,294.2 per 100,000. DALYs increased from 2,040.4 to 7,323.4 per 100,000, while absolute mortality doubled from 45.5 to 101.0 per 100,000. In contrast, the ASDR decreased from 1.2 to 0.8 per 100,000. The ASIR and ASPR increased from 12.5 to 19.4 and from 199.9 to 328.6 per 100,000, respectively.

The Joinpoint models showed a significant increase in incidence (AAPC 1.33%) and prevalence (AAPC 1.48%), a decrease in mortality (AAPC −3.21%), and a slight reduction in ASYR (AAPC −0.77%).

Table 1. Age-standardized rate* of mortality, incidence, prevalence, and DALYs for rheumatoid arthritis (≥35 years) 1990–2021)

Year	1990				2021			
	ASDR	ASIR	ASPR	ASYR	ASDR	ASIR	ASPR	ASYR
Both	1.2 (1.3–1.1)	12.5 (13.7–11.3)	199.9 (226.9–176.8)	47.0 (57.4–38.3)	0.8 (0.9–0.6)	19.4 (21.4–17.7)	328.6 (368.9–290.4)	55.8 (72.5–41.1)
Men	1.0 (1.0–0.9)	6.24 (6.95–5.57)	94.7 (110.7–80.7)	29.3 (34.6–24.9)	0.4 (0.5–0.3)	9.38 (10.50–8.31)	148.7 (174.0–126.9)	25.4 (34.7–18.7)
Women	1.4 (1.5–1.2)	18.4 (20.3–16.7)	301.3 (340.9–264.6)	64.1 (79.5–50.4)	1.1 (1.3–0.9)	28.9 (31.9–26.2)	495.7 (556.2–439.1)	83.6 (108.3–61.4)

*per 100,000 persons (95% CI); ASDR, age-standardized mortality rate; ASIR, age-standardized incidence rate; ASPR, age-standardized prevalence rate; ASYR, age-standardized DALY rate.

Conclusions

In Ecuador, between 1990 and 2021, RA showed an epidemiological transition characterized by a sustained decrease in ASDR, a persistent increase in incidence and prevalence, and a relative stabilization of the burden of disability, with a disproportionately greater impact on women.

P527

SEX- AND DISTRIBUTION-SPECIFIC PROSPECTIVE MUSCLE-FAT-FRACTURE RELATIONSHIPS IN UK BIOBANK

E. M. Curtis[1], S. X. Lin[1], S. D'Angelo[1], L. Westbury[1], R. Moon[1], C. Cooper[1], K. A. Ward[1], N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objectives

We aimed to quantify the prospective associations between site-specific MRIderived fat and muscle volumes and incident fracture in the UK Biobank Imaging Study.

Materials and Methods

We analysed data from UK Biobank Imaging Study participants with MRIderived visceral adipose tissue volume (VAT), abdominal subcutaneous adipose tissue volume (ASAT) and thigh muscle volume (TMV) as exposures. The primary outcome was first osteoporotic fracture, ascertained via hospital record linkage. Cox proportional hazards models were used to estimate hazard ratios (HRs) per standard deviation (SD) increase in each exposure, adjusting for age, socioeconomic deprivation, smoking, exercise, diabetes, and prior fracture. Femoral neck bone mineral density (BMD) adjustments were applied in sensitivity analyses. Participants were followed until first osteoporotic fracture, death, loss to followup or 31 March 2023.

Results

The dataset comprised 50,151 participants (mean age: women 63.7 years; men 65.1 years) with MRI data. 806 incident osteoporotic fractures occurred during a total 223,069 person-years follow-up time. In fully adjusted models, higher ASAT was consistently associated with lower fracture risk in both sexes [women HR/SD(95%CI): 0.67(0.60–0.74); men 0.79(0.67–0.93)], with similar findings for VAT [women 0.67(0.59-0.75); men 0.82(0.71-0.95)]. These associations remained robust after adjustment for BMD, except for VAT in men. Greater TMV was associated with lower fracture risk in women [0.74(0.64-0.86)] but this relationship was substantially attenuated by adjustment for BMD [0.92(0.78-1.08)], and there was no evidence of an association in men [1.03(0.83-1.28)].

Conclusions

Greater fat volume in subcutaneous or visceral compartments was protective against incident osteoporotic fracture in both sexes, as was

greater thigh muscle volume in women, but not men. Associations between incident fracture and visceral adipose tissue (men) or thigh muscle (women) volume appeared BMD-dependent. These findings inform fracture risk assessment and biological understanding of body composition in skeletal health. (UK Biobank access application 3593).

P528
OSTEOPOROSIS AND QUALITY OF LIFE

E. Martin Castillo[1], N. A. Abbas Khoja[1], A. Baez Suarez[2]

[1]Hospital Universitario de La Palma, Breña Alta, Spain; [2]Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Objective Describe the impact on quality of life in a patient with a recent diagnosis of osteoporosis.

Materials and Methods Description of a clinical case

Results
An 85-year-old patient, with a single personal history of high blood pressure, with a very good quality of life, who attended a rehabilitation consultation for low back pain with irradiation to the left hip for 3 days, sudden onset when getting up. On physical examination, the spine stands out: no pain on palpation of the spinous processes, no palpable trigger points. Limited joint balance from the beginning of all routes. In the left hip there are no inflammatory signs, pain on palpation in the inguinal ligament, limited joint balance in all areas due to pain. Impossibility to walk.In the plain radiograph, degenerative changes with spondylosis deformans, osteophytes and syndesmophytes were observed in the lumbar spine, without apparent signs of fracture. The MRI also shows a L1 fracture that affects the superior plate with extension to both the anterior and posterior walls, without significant displacement with minimal decrease in the height of the vertebral body. Associated bone edema. Bone densitometry shows T-score 1.1 in the spine and T-score 3.0 in the femoral neck. Given the results of the analgesic treatment regimen with Tramadol, treatment with Denosumab and Calcium was initiated. After a month of rest and treatment, the patient has gone from pain of 10 points on the VAS to 2 and has been able to restart walking without assistance.

Conclusion
Osteoporosis can cause fractures without requiring impact, so it can seriously affect the quality of life of patients.

P529
IMPORTANCE OF USING FRAX IN DAILY CONSULTATION

E. Martín Castillo[1], J. Medina Díaz[1], A. Baez Suarez[2]

[1]Hospital Universitario de La Palma, Breña Alta, Spain; [2]Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain

Objective Describe the importance of using the Frax Scale in daily consultation in patients with previous fractures.

Materials and Methods
Description of a clinical case.

Results
2-year-old patient who came for evaluation for osteoporosis screening derived from the Traumatology Service after a D8, L1-L4 fracture after an accidental fall. The patient reports that more than 10 years ago she had a fracture of the left ulna and radius after a fall from her own height, which followed orthopedic treatment with a cast. He has never had a diagnosis or previous treatment for osteoporpsis. During the consultation, a DEXA was requested with femoral T-score -3.0 and right forearm T-score -2.9. The fracture risk (FRAX) is calculated. Weighing 80Kg, height 160cm, BMI 31.2. Previous osteoporotic fracture, tobacco consumption 30 cig/day. Total Frax after fracture with DEXA 25.

Conclusion The patient is at high risk of fracture. The parameters of the FRAX calculation have not changed in recent years, so if it had been calculated from the first fracture, osteoporosis would have been diagnosed and with appropriate treatment, the following could have been reduced or avoided.

P530
MENTAL HEALTH IN HIGHER EDUCATIONAL STUDENTS

E. Matzaroglou - Chairistanidou[1], C. Matzaroglou[2], C. K. Koutserimpas[2], M. T. Tsekoura[2], K. Kaliarntas[2], E. Tsepis[2], K. Kafchitsas[2], N. Stefanopoulos[3]

[1]School of Medicine, University of Patras, Patras, Greece; [2]School of Health Sciences, Department of Physiotherpy and Department of Orthopedics, University of Patras, Patras, Greece; [3]Department of Nursing , University of Patras, Patras, Greece

Introduction: Despite the perception that Health related students [Medical - Physiotherapy and Nursing students] should be "stealth" in mental health, challenges are common in this population. These students have low levels of help seeking their own psychiatric problems often only presenting to mental health services once a crisis arises.

Material and Methods: We set out to investigate "Health students" mental health. The questionnaire consisted of the Hospital Anxiety and Depression scale (HADS) and the Sense of Coherence scale (SOC-3) questionnaires, evaluation of suicidal risk, self-rated health status (SRHS).

Results: Among 145 students who completed the survey, the prevalence of clinically relevant anxiety was high (42.5%) and contrasted with the lower prevalence of depression (10.33%). 17.5% of all students admitted that they had thought about suicide at least once during their lifetime and a similar number of students thought about suicide during the previous year. High levels of anxiety and depression were statistically significant predictors of suicidal ideation and planning during the past year in binary regression models.

Conclusions: Fear of exposure to stigmatisation is a crucial factor contributing to symptom concealment and is a barrier to accessing mental health services. Our study highlights anxiety and suicidality to be burdensome mental health issues among higher education students [Medical - Physiotherapy and Nursing students] in Greece.

Keywords: Mental health, Anxiety and Depression, Medical students, Physiotherapy students

PREVALENCE OF PATIENT SELF-REPORTED FRACTURE RISK FACTORS – PRELIMINARY ANALYSIS OF A DIGITAL STUDY IN THE PRIMARY CARE SETTING (THE SELF-FRAX STUDY)

M. Paggiosi[1], S. Wathall[2], H. Johansson[3], A. Sturrock[4], S. Nedungayil[5], E. Curtis[6], J. Edwards[7], E. McCloskey[8]

[1]Mellanby Centre for Musculoskeletal Research, Division of Clinical Medicine, School of Medicine & Population Health, University of Sheffield, Sheffield, United Kingdom; [2]Keele Clinical Trials Unit (CTU), David Weatherall Building, Keele University, Keele, United Kingdom; [3]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [4]NHS Education for Scotland Hospitals and Health Care, Edinburgh, United Kingdom; [5]East Lancashire Hospital NHS Trust, Rossendale, United Kingdom; [6]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [7]Wolstanton Medical Centre, Wolstanton, Newcastle-under-Lyme, United Kingdom; [8]Mellanby Centre for Musculoskeletal Research, Division of Clinical Medicine, School of Medicine & Population Health, University of Sheffield,, Sheffield, United Kingdom

Objective: The SELF-FRAX study aims to explore the concordance between patient self-reported risk factors and risk factor documentation within the GP electronic patient record (EPR) with the hope of enhancing and automating fracture risk assessments in primary care to improve treatment access. The aim of the current analysis is to describe recruitment and present the prevalence of self-reported risk factors.
Materials and Methods: Across England, a total of 181 GP practices using SystmOne EPR software were recruited through the NIHR Research Delivery Network. Eligible patients within each GP practices were identified and 500 were randomly approached comprising 125 in each of four groups (men: 50-65 years, >65 years; women 50-65 years, >65 years). Patients were invited to participate via a GP practice-generated SMS message containing a URL directing them to study information, an e-consent form and an online questionnaire including the FRAX risk factors. Paper forms were available to patients without an active mobile phone number or by request.
Results: Approximately 90,500 patients were approached and 5707 questionnaire responses (99% digital) collected (response rate 6.3%). Participation rate was greater in women than in men (8.1% vs 4.5%) with a lower mean age in women than in men (64.3 vs. 67.4 years, p<0.001). Risk factor prevalence was highest for previous fracture (similar in women 39.1% and men 40.6%) and lowest for current smoking (similar in women 5.6% and men 4.7%). The prevalence of most FRAX risk factors was similar in men and women, but women reported a slightly higher prevalence of parental hip fracture (16.5% vs 12.7%, p<0.001) but a lower prevalence of alcohol intake of 3 or more units daily (6.6% vs. 16.4%, p<0.001).
Conclusions: Despite a relatively low response rate, SELF-FRAX is one of the few studies to compare self-reported rates of risk factors in men and women in UK primary care. The prevalences are comparable to those reported in other studies in women. Further analysis will determine the concordance with risk factors in the EPR and determine whether a combination of patient self-reported and EHR data may permit enhanced risk assessment and intervention to mitigate future fracture risk.

P533

IMPACT OF POST-HIP FRACTURE ANTI-OSTEOPOROTIC THERAPY ON MORTALITY: A REAL-WORLD STUDY

E. Monleón Acosta[1], J. A. Rodríguez Fernández[1], P. J. Manuel Hernández[1], A. López Lisón[1], M. R. Oliva Ruiz[1], J. M. Andreu Ubero[1], A. Pérez González[1], G. Albaladejo Paredes[1], P. V. Castillo Dayer[1], C. Fernández Díaz[1], A. Egea Fuentes[1], M. Fernández Salamanca[1], V. Cogolludo Campillo[1]

[1]Hospital Universitario Santa Lucía, Cartagena, Spain

Objectives:

• To evaluate the impact of post-hip fracture anti-osteoporotic therapy and calcium/vitamin D supplementation on mortality.

• To assess the association between the type of anti-osteoporotic agent and mortality.

• To assess whether the implementation of a fracture unit coordinated by a bone metabolism expert would be beneficial.

Methods:
A retrospective observational study was conducted at Hospital Santa Lucía, including patients with osteoporotic hip fractures between January 2017 and January 2023. Statistical analysis was performed using SPSSv21.
Results:
1068 patients were included. 22.2% had a previous osteoporotic fracture. Only 2.6% had received osteoporosis-specific treatment before the fracture. Post-hip fracture, osteoporosis treatment was prescribed in 20.4% of patients and 41.3% received calcium/vitamin D supplementation.
A significant association was found between post-hip fracture osteoporosis treatment and reduced mortality ($p = 0.04$). Patients not receiving anti-osteoporotic therapy had a mortality rate of 49.1%, while those treated had a significantly lower rate of 23.85% ($p = 0.04$).
Stratified by anti-osteoporotic regimen, mortality were 24.8% for denosumab, 22.7% for bisphosphonates, and 14.28% for teriparatide. Standardized residual analysis revealed that survival was significantly higher in patients treated with bisphosphonates (residual = 2.2) and, particularly, denosumab (residual = 4.8), ($p = 0.004$). Calcium/vitamin D supplementation post-fracture also showed a significant association with lower mortality ($p = 0.033$). Patients followed by a bone metabolism expert had a significantly lower mortality rate compared to those without follow-up ($p < 0.005$).
Conclusions:
Our data shows a significant reduction in mortality in patients receiving anti-osteoporotic treatment and calcium/vitamin D supplementation. Denosumab showed the lowest mortality. Despite these findings, fewer than 25% of patients received post-fracture osteoporosis treatment. Mortality was also lower in patients followed by a bone metabolism expert, showing the benefits of specialized osteoporosis management. These results support the potential advantages of implementing a fracture unit coordinated by a bone metabolism expert.

P534

MEDICATION-RELATED OSTEONECROSIS OF THE JAW: THE IMPACT OF THERAPY INDICATION

E. Monleón Acosta[1], J. A. Rodríguez Fernández[1], P. J. Manuel Hernández[1], A. López Lisón[1], J. M. Andreu Ubero[1], M. R. Oliva Ruiz[1], A. Pérez González[1], G. Albaladejo Paredes[1], P. V. Castillo Dayer[1], C. Fernández Díaz[1], A. Egea Fuentes[1], V. Cogolludo Campillo[1]

[1]Hospital Universitario Santa Lucía, Cartagena, Spain

OBJECTIVE
To analyse which drugs are associated with the development of medication-related osteonecrosis of the jaw (MRONJ).
METHODS
A retrospective observational study was conducted at Hospital Santa Lucía, including diagnosed of MRONJ between 2015 to 2025.
RESULTS
We recollected 34 individuals with MRONJ. 55,9% were women. The average age was 69 +- 13.2 years. Of these patients 52,9% were hypertensive, 23,5% diabetic and 8,8% had stage 3-4 chronic kidney disease. 58,8% of the individuals had an underlying oncological disease and 5,9% had a rheumatological disease. Of all people, 26,5% had previously had an invasive dental procedure.
At the time of MRONJ diagnosis, 100% of the individuals were being treated with antiresorptive drugs: 64,7% with bisphosphonates (BF) and 35,3% with denosumab. Of those on BF therapy, 59,1% were on intravenous bisphosphonates. These treatments were indicated as oncological treatment in 57,1% of cases, while only 39,3% were used as anti-osteoporotic treatment.
