PROANTHOCYANIDINS FROM RIBES NIGRUM LEAVES
TLC ANALYSIS

KEYWORDS: Ribes nigrum; Grossulariaceae; black-currant leaves; proanthocyanidins; prodelphinidins.

INTRODUCTION

The ten proanthocyanidins isolated from R. nigrum (black-currant) can be subdivided into three groups, according to the increasing degree of polymerization:
- **four monomers** including catechin 1, epicatechin 2, gallocatechin 3, epigallocatechin 4;
- **four dimers** comprising two major prodelphinidins: gallocatechin-(4α→8)-gallocatechin 5 and gallocatechin-(4α→8) epigallocatechin 6 and two minor compounds, gallocatechin-(4α→8)-catechin 7 and gallocatechin-(4α→6)-gallocatechin 8;
- **two trimers** including the new prodelphinidin gallocatechin-(4α→8)-gallocatechin-(4α→8)-gallocatechin 10 and the mixed proanthocyanidin, catechin-(4α→8)-gallocatechin-(4α→8) gallocatechin 9.

Here we report on the identification and TLC-fingerprint of these ten proanthocyanidins. The simultaneous examination of their Rf values and colorations with the vanillin-HCl reagent gives structural and stereochemical informations which is of use in the quality control of medicinal products based on R. nigrum leaves.

EXPERIMENTAL

Each proanthocyanidin solution was prepared by dissolving 1 mg of substance in 1 ml methanol. The solutions (10μl) were spotted on HPTLC silicagel 60F254 plates (10 x 20 cm) Merck® as 5 mm. bands. Plates were developed in the ascending mode in a saturated chamber (15 min) at room temperature, using the upper phase of ethyl acetate-water-formic acid-acetic acid (70:20:3:2;v/v/v/v) as mobile phase [1]. Following development, the plates were dried and sprayed with a 1 % vanillin solution in methanol-hydrochloric acid.
acid (8:2;v/v). The colours of the bands were observed 5 min and 24 hours after spraying. The Rf values were as follows: 1(0.89), 2(0.875), 3(0.80), 4(0.78), 5(0.41), 6(0.42), 7(0.51), 8(0.6), 9(0.21), 10(0.15).

RESULTS AND DISCUSSION

Examination of the plates 5 min. after spraying with vanillin-HCl reagent showed that flavan-3-ols (monomers and oligomers) afforded a red colour, which allows the proanthocyanidins and flavonoids present in the leaves of R. nigrum to be distinguished; however, the next day, re-examination of the plate allowed some of the stereoisomers to be differentiated. Prodelphinidins comprising gallocatechin unit(s) only (3,5,8,10) changed to violet at room temperature, while those containing epigallocatechin unit(s) (4,6) became browner. Evaluation of the Rf values revealed a characteristic TLC finger-print for the R. nigrum proanthocyanidins.

Four points may be noted:
I. Rf values decrease with increasing degree of polymerization (Rf 0.75-0.9 for monomers; 0.4-0.6 for dimers and 0.15-0.3 for trimers). This order is the same on silica gel with dibutyl ether-diethyl ether-isobutanol-acetic acid (5:2:2:1;v/v/v/v) [2]; nevertheless, this solvent system does not provide a good separation between the dimers and trimers. On cellulose, the Rf values do not depend on the average molecular weight.
II. Procyanidins are eluted before prodelphinidins of equivalent constitution.
III. Dimers with a (4α->8) inter-flavan linkage are eluted after their (4α->6) isomers; this elution order is reverse of that described earlier on Sephadex LH 20.
IV. Rf values of C-3 diastereoisomers are too close to allow quantitative densitometric determination of each constituent. The HPTLC method, however, can be used for the quantitative determination of some of the major oligomeric prodelphinidins. These observations corroborate and complete the previous studies on the chromatographic behaviour of flavan-3-ols [3].

In summary, the main oligomeric prodelphinidins of R. nigrum leaves can be identified by HPTLC; this method could also be utilized as a proanthocyanidin screen for determining their occurrence in other plants and for quantification of the major dimers. We are currently investigating the development of an appropriate densitometric method.
